The ground area of the large sub-station in Waterbury, known as sub-station No. 1, is 125 feet by 78 feet, and its elevation includes a high basement and main operating room or first floor above, together with a somewhat lower structure running along the side as shown by the sectional elevation in Fig. 3. From ground to coping the height of the station is 28 feet;

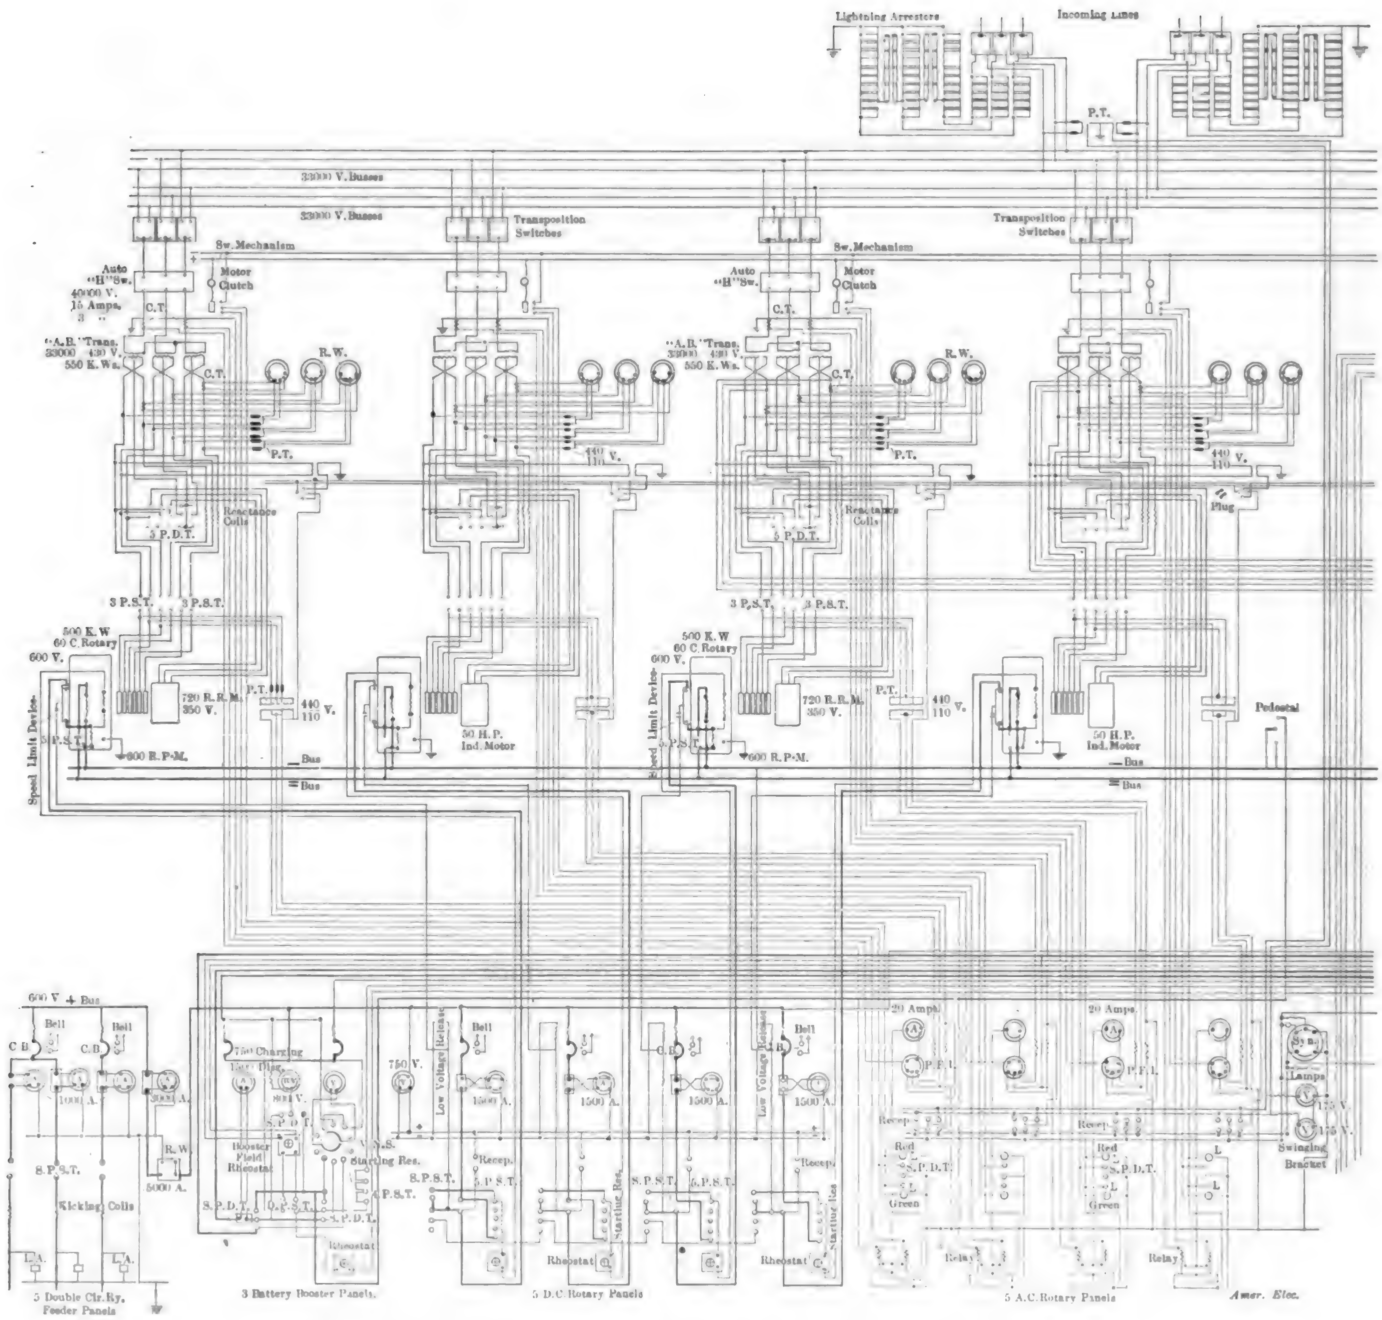

FIG. 11.—DIAGRAM OF SWITCHBOARD CONNECTIONS, WATERBURY SUB-STATION NO. 1.

high-tension tower and running almost the entire width is a weather shield having a roof of concrete on expanded metal, with one inch slate sides and ends projecting downward a distance of 27 ins. Eighteen inches below the roof of this projection and supported on T-iron extensions is a slab of one-inch slate completely closing the shield. This slab is pierced by six porcelain floor tubes placed 26 ins. apart and in a line 11 inches from the building wall to the center of the tubes. Resting in 22-inch openings in the wall, 4⅜ ins. from the inner side to tube. The insulators in the wall are separated by a 4-in. partition.

After passing through the weather shield and openings in the wall the six bare wires of the transmission circuits enter single-throw double-blade knife switches which connect each wire with a bank of lightning arresters and with duplicate 33,000 volt bus-bars in the basement. Double-blade jack-knife switches tap these bus-bars and connect them with 30,000-volt motor-driven oil-break switches. From here the circuit leads to 550-kw. three-phase transformers and from basement to main floor the distance is 10 feet, while the distance from the main floor to the lower cord of the steel roof trusses is 18½ feet.

In structure the sub-station is of brick, concrete and steel. The walls are 12 inches thick, which is increased to 16 inches at buttresses. The basement floor is formed of a one-inch layer of cement on nine inches of concrete, and the main floor is composed of concrete arches resting on steel I-beams and all supported by the outer and by 16-in. interior walls. The floor of

the adjacent room, which is used as a storage battery room, is composed of six inches of concrete covered with four and one-half inches of vitrified brick. Two towers, one on either side of the main building, as shown in the plan view, Fig. 2, 40 feet high with an interior space 13 feet square, are used for high-tension and low-tension transmission wires, the tower nearest the river being used for high-tension wires. by brick abutments. A small gallery on the side nearest the river contains the lightning arresters and knife switches for the incoming high-tension lines. These pass directly to the basement, a narrow chamber formed by partition walls being provided for the purpose of isolating them from the main floor.

The air lock doors for the air-pressure chamber are 2¾ feet by 7 feet. They are has a ⅛-in. rubber gasket on each end. A 4-in. hole is provided in the door so that when the outer door of the air lock chamber has been shut this hole may be uncovered and the pressure on either side of the door equalized, thus permitting the door to be opened with ease. The hole is provided with a 1/16-in. rubber gasket and is covered with a heavy iron flap hinged at the top.

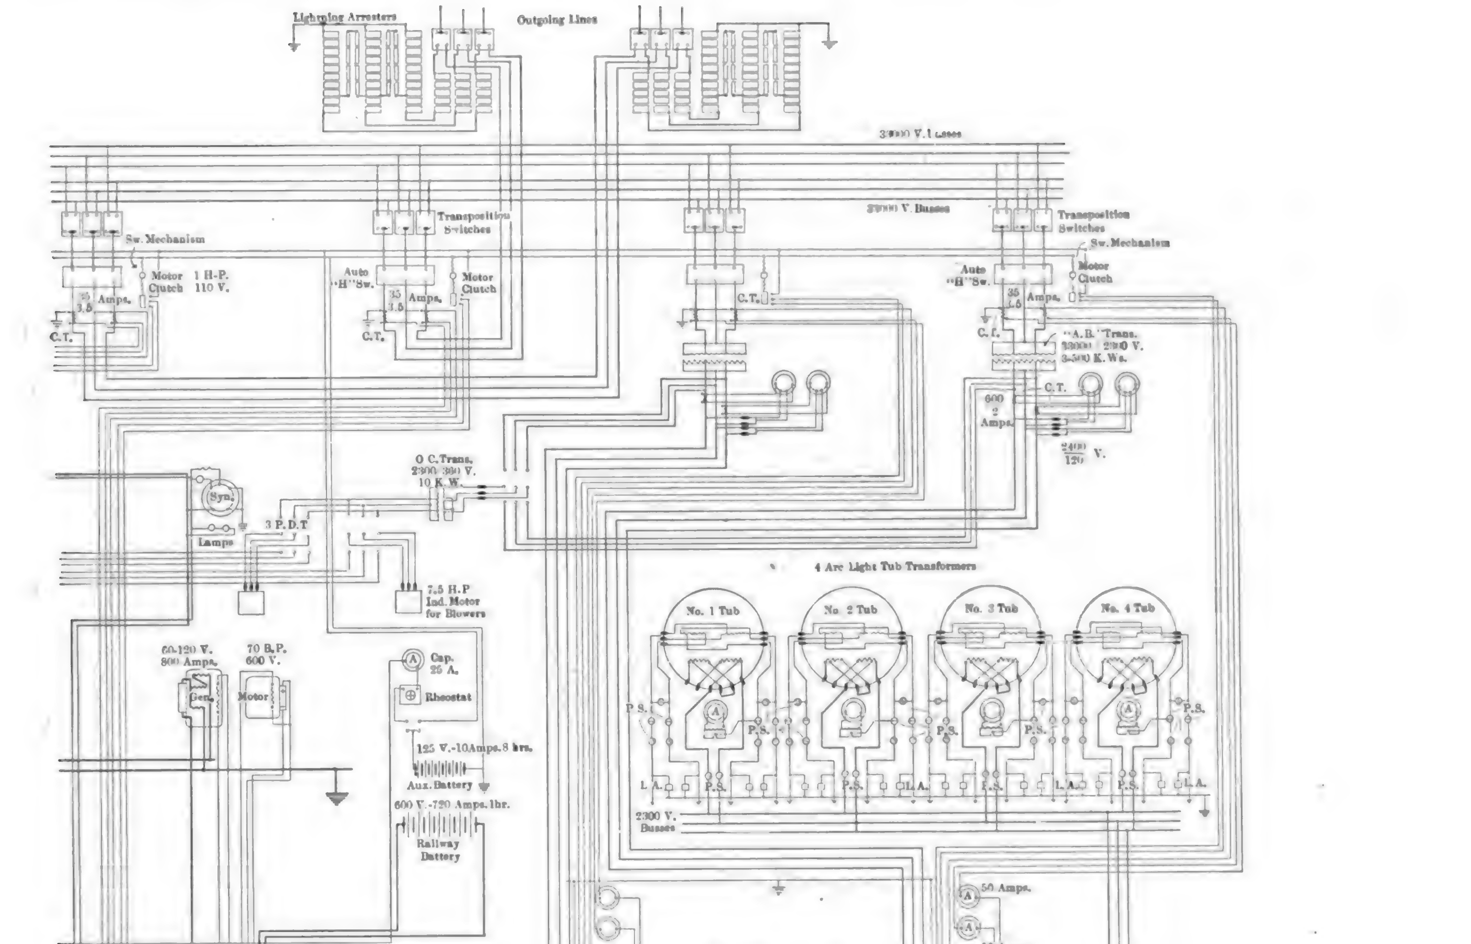

FIG. 12.—DIAGRAM OF SWITCHBOARD CONNECTIONS, WATERBURY SUB-STATION NO. 1.

The station is lighted by large windows along the sides and by windows in the monitor roof running along the center of the main building.

The basement is divided by 16-in. interior walls into spaces for air pressure chambers, bus-bar compartments and oil switch cells. The air pressure chamber is 19 feet wide and all high-tension bus-bars are located therein. The main floor, which is 113 feet long by 50 feet wide, is swept by a ten-ton traveling crane. The I-beams on the side walls of the station are supported made of 3/16-in. plate riveted to a 2-in. by 2-in. by 3/16-in. L-iron frame and hinged to the wall. The handle passes through the door and catches on the curved side of the angle of a 2½-in. by 2½-in. by ¼-in. L-iron frame fastened to the wall and against which the door shuts. A ⅜-in. rubber gasket is cemented to the angle of this frame around the entire surface and the pressure of the door against this gasket precludes the escape of air from the chamber. The door may be opened from either side and the bolt passing through the door

Fig 2 is a plain view of the sub-station showing the layout of the apparatus, and Figs. 9 and 10 show photographic views of the main transformer room. The equipment housed in this station consists of four 500-kw rotary converters, one 48-kw booster, four 550-kw, 33,000-volt, 60-cycle transformers with their reactance coils, eight motor-driven, high-tension oil switches, two motor-driven blowers, six single-phase transformers, six arc light transformers, a railway storage battery and an auxiliary storage battery, together with controlling

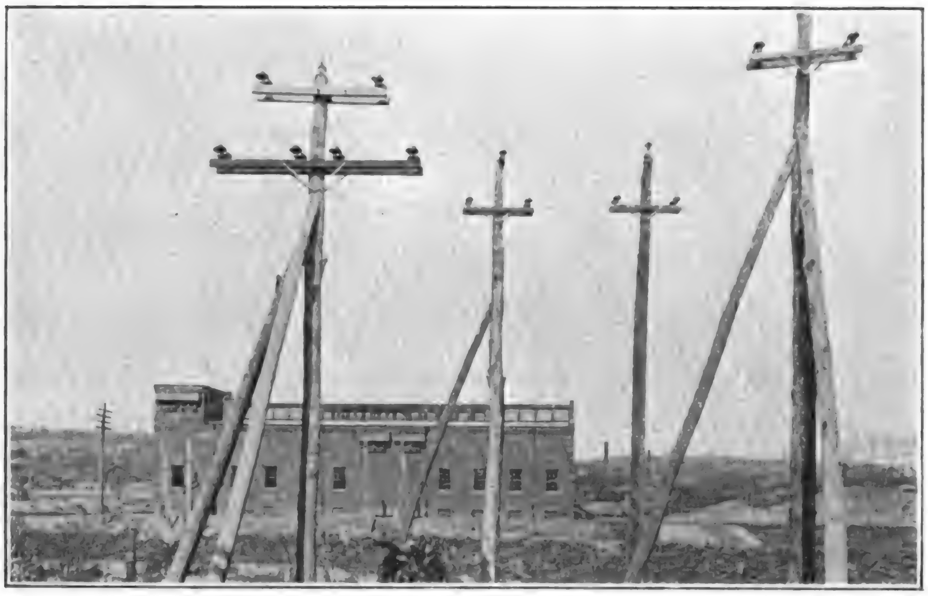

FIG. 13.—WATERBURY SUB-STATION NO. 1, SHOWING INCOMING AND OUTGOING HIGH-TENSION TRANSMISSION LINES.

switchboards. Space is provided as indicated for additional apparatus.

The transformers are all of the air blast type, the primary and secondary voltages of the 550-kw. units being 33,000 and 430, respectively. The primary and secondary voltages of the 500-kw., single-phase transformers are 33,000 and 2,300, respectively. The air pressure maintained in the chamber beneath the transformers is ⅝ oz. Two Buffalo Forge Company's fans, each direct-driven by a 350-volt, 60-cycle, 7½-h.p. induction motor, supply the air for the air pressure chamber. These units are located just beyond and in line with the large transformers about the center of the room and beside each induction motor is a switch panel carrying the necessary apparatus for throwing the motor into circuit.

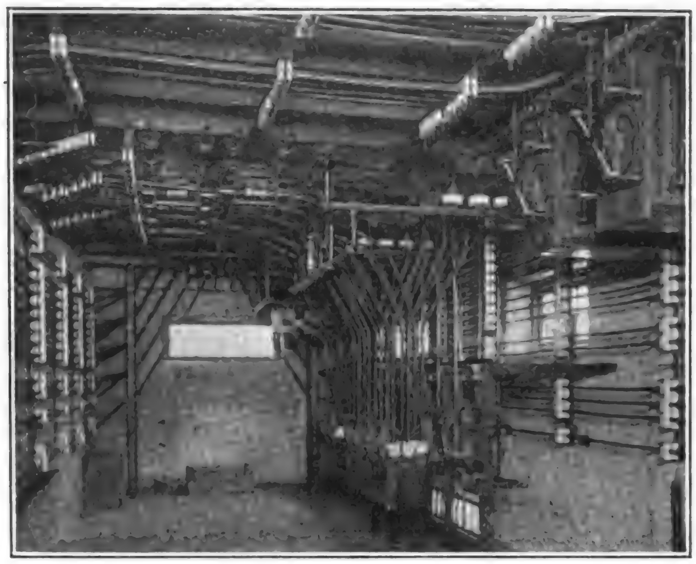

FIG. 14.—OIL SWITCHES AND REGULATORS IN BASEMENT OF SUB-STATION NO. 1.

The rotaries, of which there are four installed, are 60-cycle machines having twelve poles and running at 600 r.p.m. They each deliver 833 amperes of direct current at a potential of 600 volts. Each rotary is started from standstill by means of a 50-h.p. induction motor mounted upon the rotary converter shaft, and when the armature is thus brought up to synchronous speed connection is made to the alternating-current mains. Switches are provided for starting the rotaries as direct-current motors from the commutator end, but this method of starting is seldom if ever used. The current from the rotaries is used entirely for railway purposes, the maximum load of which is 2500 amperes, which comes on at noon.

The high - tension transformer oil switches have a capacity of 200 amperes at 30,000 volts. These switches are operated by direct-current series motors taking 11 amperes at 110 volts and running at 2,800 r.p.m. The operation of the oil switch may be accomplished by a small single-pole, double - throw, hand - controlling switch mounted on a panel of the main switchboard. Red and green lights indicate whether the oil switch is closed or open. Six breaks are provided in the triple-pole switch, each break taking place in a separate oil receptacle and in addition each phase is enclosed in a fireproof compartment. The cells are constructed of brick, with top and bottom slabs of slate. The switches installed are all automatic in operation, a relay operated by current transformers closing the direct-current operating motor circuit. Fig. 5 shows the line of large oil switches.

The six 500-kw. transformers are arranged in banks of three, and the 2,300-volt secondary current obained from them is transmitted over two separate trunk lines of No. 000 copper to sub-station No. 2 in the center of the town. The six constant-current transformers are used for series arc lighting; single-phase arc lighting circuits running to Naugatuck, North Willow and Highland Park, Waterville, East Waterbury, North Waterbury and Forest Park, Watertown, South Waterbury and Platt's Mill. The line to Watertown has a straight run of six miles before distribution is made. A three-phase feeder line also runs to Naugatuck, where it is split up into three single-phase circuits.

The storage battery used on the railway circuits consists of 288 type G-27 cells. The voltage is 600 and the rate of discharge is 720 amperes for one hour. The auxiliary storage battery consists of 55 type D-9 cells and the voltage is 110, with a discharge rate of 10 amperes for eight hours. This battery is used to supply current to the motors of the oil switches and pilots. The indescent lamps are wired five in

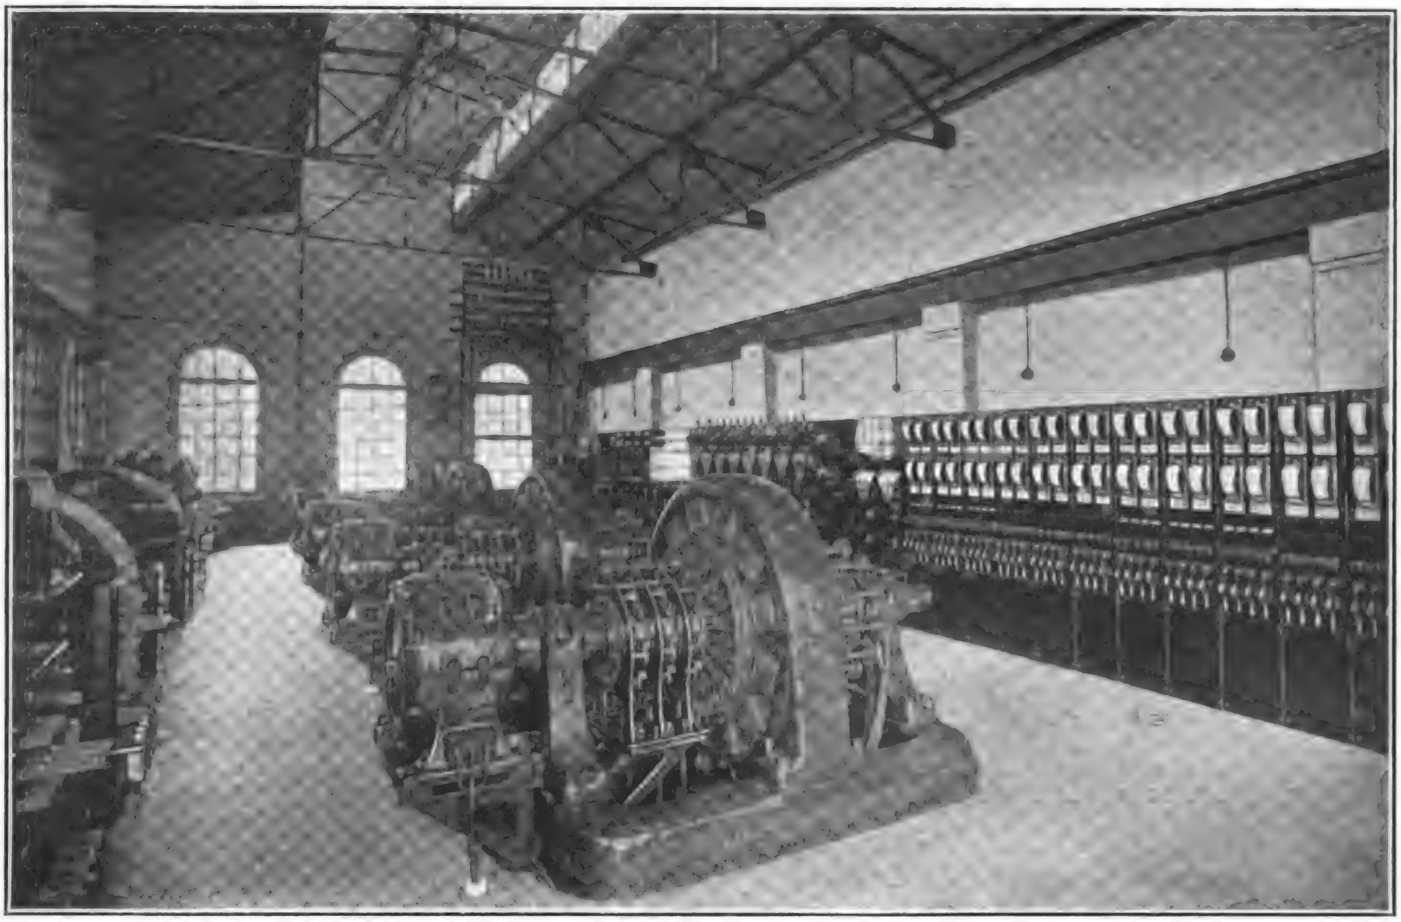

FIG. 16.—GENERAL VIEW OF THE INTERIOR OF WATERBURY SUB-STATION NO. 2.

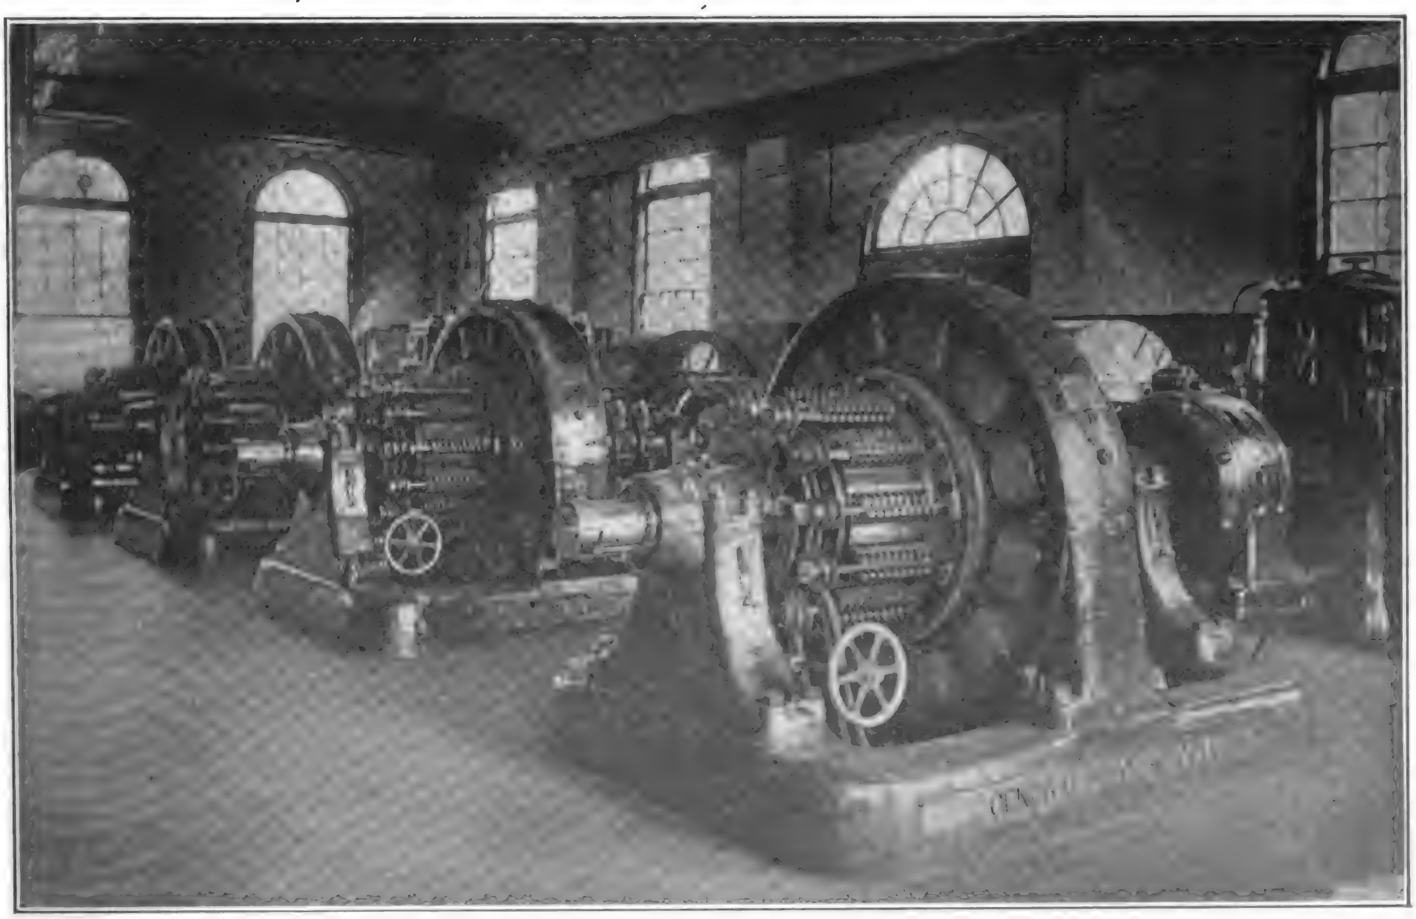

FIG. 17.—NEARER VIEW OF ROTARY CONVERTER S FROM THE DIRECT-CURRENT END.

series with a 2,300/500 volt transformer to a supply circuit. In case of shut down at New Milford a throw-over switch connects these circuits with the main storage battery so that the station will at no time be without light. The alternating-current enclosed arc lights with which the station is bountifully provided are fed from a separate 104-volt transformer circuit in the station.

A view of the switchboard is shown by Fig. 7 and a diagram of its connections cut in two for convenience of printing, is shown in Figs. 11 and 12. The board is made of black enameled slate and contains 40 panels, distributed as follows: Five double-circuit railway feeder panels, five single-circuit feeder panels, three battery-booster panels, four direct-current rotary panels, four three-phase power panels, two three-phase trunk line panels to sub-station No. 2, one totalizing panel for arc light circuits, one three-phase panel, six single-phase lighting panels and three sectioning panels. The circuit-breakers, ammeters, rheostats, hand-wheels, switches, etc., are of uniform design and occupy the same position on all panels thus giving a symmetrical appearance to the switchboard. The circuit-breakers on the railway feeder panels are equipped with a tell-tale device which completes the circuit of an alarm bell when the breaker opens. The device is automatically reset when the breaker is closed again. The circuit-breakers on the converter panels in addition to having this tell-tale device have low-voltage release coils which trip the breakers when the voltage drops below a certain point. The low-voltage release coil is used in connection with a centrifugal speed limiting switch mounted on the shaft of the rotary, and which short-circuits the low-voltage release coil and opens the circuit-breaker in case the speed exceeds the normal.

The panels controlling the 2,300-volt three-phase and single-phase circuits are grouped together, but the bus-bars are divided into four sections by three section switches, thereby giving great flexibility in the matter of connections. The power circuits, trunk-line circuits, arc-light circuits and incandescent circuits are all metered separately. Oil switches are used on these

panels, the operating mechanism being controlled by the switch through rods passing through the floor. Fig. 14 shows the oil cells and regulators in the basement beneath the switchboard. The oil switches are electrically tripped on overload, with the exception of the sectioning switches which are not equipped with the electrical releasing device. The device is shown clearly beneath the switches in the engraving of the switchbooard, Fig. 7. Practically all of the wiring is run in the basement, where ample room is provided in which to work. No wires carrying high-tension current are brought directly to the switchboard. 450 series arc lamps and about 30,000 incandescent lamps are fed from this station.

Sub-station No. 2 is somewhat smaller in size and equipment than the sub-station just described and covers an area 35 feet by 70 feet. A plan view of the station and its equipment is shown by Fig. 18, and Figs. 16 and 17 are photographic views of the rotaries. The incoming trunk lines from Sub-station No. 1 may be seen in the background of Fig. 16. These pass directly to the bus-bars and switches in the basement.

The equipment of the station consists of four 300-kw. rotary converters, with their starting motors, four 300-kw., three-phase transformers with potential regulators and two motor-driven fans together with a switchboard running along the side almost the entire length of the station. That portion of the basement beneath the transformers is laid out as an air-pressure chamber, while that portion below the switchboard contains the oil switches, busbars, regulators, etc., as shown in Fig. 20.

The converters are 60-cycle machines, running at 600 r.p.m. and delivering direct-current at 275 volts. They are brought up to speed by 30-h.p. induction motors, but may be started from the direct-current side also. Space is provided for additional machines. The transformers have a primary voltage of 2,300 volts and secondary voltage of 188 volts. The fans are of the Buffalo Forge Company's make and are driven by a 5-h.p., direct-current motor at 400 r.p.m. The air pressure maintained is ⅜ oz. Four I-T-R potential regulators are installed, each being operated by a ¼-h.p. induction motor. These regulate the alternating-current voltage delivered to the transformers. Almost all the regulation is obtained in this way, very little being possible from the direct-current end. The panel in front of each regulator contains a three-point, double-throw starting switch, a single-throw neutral switch and two double-pole, double-throw, alternating-current running switches.

The switchboard is shown in Fig. 22 and a diagram of its connections is shown by Fig. 21. It is equipped with high and low voltage bus-bars and the switches are double-throw, so that when thrown up they connect with the high voltage bus, and when thrown down they connect to the low-voltage bus. The high-voltage busbars are, however, not at present in use. The board contains 12 feeder panels, having 48 feeder switches, one-half of which

are only at present connected. The station is devoted entirely to power and lighting work on the Edison three-wire system.

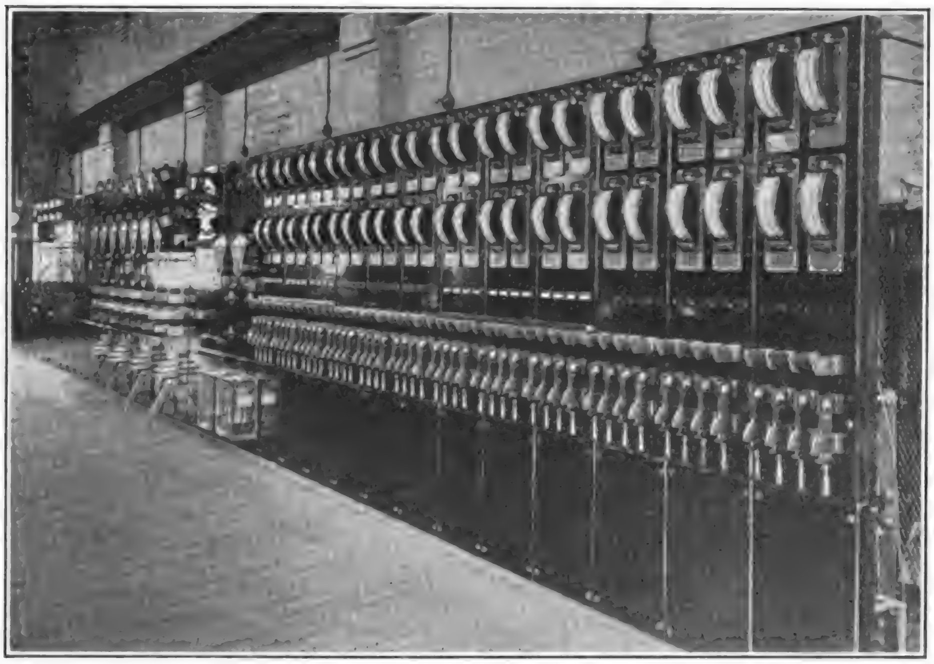

FIG. 22.—SWITCHBOARD, WATERBURY SUB-STATION NO. 2.

The territory fed by the station is about one square mile, the station being at about the center of the load. Overhead wires are at present used, but by the time this article appears, work will be commenced on an underground conduit system. The commercial multiple-arc lamps connected number abut 900 and the incandescent lamps number over 20,000. The entire electrical equipment of the Connecticut Railway & Lighting Company's sub-stations at Waterbury, including series and multiple arc lamps, as well as the electrical equipment of the New Milford Company's hydroelectric station at Bulls Bridge was supplied by the General Electric Company.

The load in Waterbury was previously carried by a steam-driven central station on Bank Street bordering on the Naugatuck River. This station is now maintained as a reserve in case of any accident to the transmission plant at Bulls Bridge; but this is so well guarded against that a failure of supply is almost impossible, and it will be only a matter of time when the old steam station will be dismantled. The superintendent of the Waterbury station is Mr. D. B. Neth, to whom we are indebted for many courtesies extended in the preparation of this article.

MOTOR-CONTROLLING APPARATUS.

BY FRANCIS W. APPLETON.

The development of the variable-speed motor has brought with it much improvement in the design and construction of motor-controlling apparatus, but there yet remains room for some improvement. The many automatic or semi-automatic motor starters now in use constitute a highly commendable step forward, and the combined starting and speed-regulating "boxes" which represent the latest development in this field are wonderfully complete in their functions and are reasonably reliable in service. It is undeniably true, however, that electrically operated mechanisms for starting motors from a distance have not been brought to the "irreducible minimum" of parts, nor do the electrical contacts in such appliances represent the final effort in the way of design.

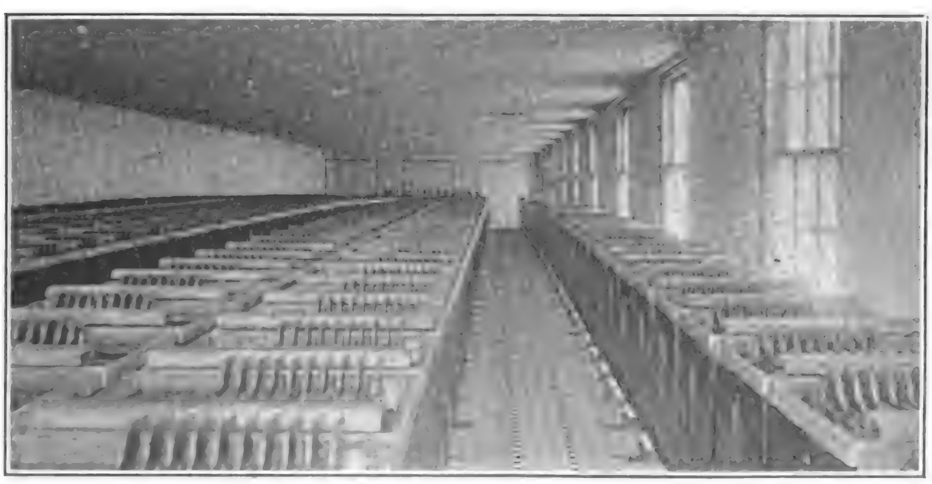

FIG. 23.—STORAGE-BATTERIES IN WATERBURY SUB-STATION NO. I.

Sliding contacts have the great advantage of keeping themselves mechanically clean—until arcing occurs; then they degenerate into the least reliable of all moving contacts. If made of carbon, to minimize the effects of arcing, they wear away very rapidly and very unevenly. On the other hand, butt contacts of carbon are not affected by ordinary arcing and their wear is trifling, but they are liable to accumulate dust and particles of charred carbon which seriously impair the efficiency of the contacts.

It would seem evident from the foregoing well-recognized facts that the nearest approach to perfection that is attainable in the present general "state of the art" in motor-controlling apparatus would be realized by the use of carbon butt contacts which have a slight sliding motion after coming into touch, with a leaf-copper yielding butt contact to short-circuit the carbons after the last one of the latter has closed. This is doubtless true, and the writer is strongly of the opinion that a motor-starter built on this fundamental idea will give more reliable service, with vastly less attention and repairs, than the old-fashioned sliding brush and row of contact plates or a series of metal butt contacts.

In order to make up a starting apparatus of the type just mentioned, it is necessary to use at least four or five expensive solenoid switches, together with an overload relay to open-circuit the switches at a predetermined load. Such an outfit is ideal from a purely engineering standpoint, but its cost is prohibitive in all cases except highly special ones, such as passenger elevators, printing presses, or large motors that must be started and stopped from a distance.

The writer recently saw in successful operation a crudely simple arrangement consisting of a number of carbon-faced contact fingers and a leaf-copper contact which, when closed, short-circuited all of the carbons after all of the armature resistance was cut out by them; a solenoid and a dashpot controlled these contacts, and a small relay magnet connected in series with the motor armature served to open the exciting circuit of the solenoid when the load reached a certain point beyond the rated ability of the motor. This outfit has been in active operation for eight months without a hitch, with no attention whatever, no renewal of contacts or other repairs having been found necessary; it starts a 35-h.p., 220-volt motor dozens of times daily, and the acceleration is smooth, without any sparking at the motor brushes and with practically no arcing at the carbons, except for the slight flash at the first carbon when the motor is cut off while under a heavy load.

The control of motor field excitation is a simpler matter than that of armature circuit, and for this class of work sliding contacts are less annoying; but an arrangement somewhat similar to that just described would undoubtedly prove far more satisfactory in all ordinary cases. The application of such an arrangement to the control

of a sectional conductor, whether inductive or not, confers the immense advantage that fewer divisions of the conductor are necessary than when sliding contacts are used, the operation of butt contacts being affected to only a negligible extent by arcing. For example, the motor starter already described had only five contacts, four of which cut out dead resistance coils and the fifth short-circuited a heavy series field winding. It requires very little imagination to picture what would happen if an attempt were made to cut in and out such a combination by means of a swinging arm traveling over contact plates.

In conclusion, it may be well to state that the writer has no interest, pecuniary or otherwise, in the manufacture or sale of motor-controlling appliances; the worse service they give in his immediate vicinity, the more profitable is his occupation likely to be. The most cursory comparison of the actual performance of a sliding-brush apparatus and that of a combination of solenoid switches will readily vindicate the argument here advanced, and the simplified arrangement described is, of course, merely a condensation of solenoid switches.

THE SEPARATION OF MOISTURE FROM STEAM.

BY R. T. STROHM.

The steam which is discharged from the ordinary steam boiler is in most cases initially wet. This is due to the method of formation of the steam. Take, for example, the return tubular boiler. With the application of heat to the water after the boiling point is reached, steam globules are formed along the water surface of the lower plates. These globules, being much lighter than the volume of water which they displace, rise rapidly to the surface of the water. In so doing, they likewise expand slightly, and upon reaching the surface, break through the thin skin on the water surface, and burst. This breaking through and bursting results in throwing a fine mist or spray of hot water upward into the steam space, and the more rapid the boiling, the more violent is this action.

Inasmuch as the water spray thus projected into the steam space is quite finely divided, it is easily held in suspension in the steam and carried along with the current. Consequently, in the case of a boiler which is being forced to its utmost, considerable moisture is thrown into the steam, and is the action which engineers commonly call priming. The percentage of moisture in steam varies greatly, depending upon the details of construction of the boiler, the amount of liberating surface, and the conditions under which the boiler is operated. Ordinarily, however, with normal loading and a fairly well-designed boiler, there is from 2 to 8 per cent of moisture in the steam at the boiler nozzle, while under less favorable conditions the percentage of moisture easily reaches 15 per cent and frequently runs much higher.

Neglecting the moisture which is entrained by the steam before leaving the boiler, the steam entering the cylinder of the engine would still contain more or less moisture, due to the unavoidable loss of heat because of radiation during its passage through the steam pipe. The amount of condensation brought about in this manner depends upon the length of the pipe, the quality of its covering, and the relative temperatures inside and outside the pipe.

As a consequence of the presence of moisture in the steam, it becomes desirable to remove this water for three good reasons: First, the safety of the engine; second, economy; and third, the better lubrication of the engine.

Consider the first reason. Water is practically incompressible. Therefore, if any great amount of it should get into the cylinder and be caught in the clearance space during compression, there would be considerable likelihood of a cracked cylinder, piston or head, or perhaps a buckled rod. It is true that drain cocks properly fitted to the cylinder will remove all ordinary collections of moisture; also, in engines of the Corliss type, the exhaust valves are in such positions as to drain the cylinder quite readily. However, if a boiler primes or foams badly, water may be carried over to the engine in such quantities that the drain cocks cannot possibly discharge it rapidly enough to prevent damage to the engine.

Next, consider the question of economy. It is evident that if the condensation passes through the engine and is thrown out with the exhaust, it loses much of its heat, so that even if it is returned to the boilers, together with the condensed steam, there is a definite loss. On the other hand, if this condensation is removed from the live steam, and immediately returned to the boilers, it will require little more heat to bring it to the temperature of vaporization, since it will have very nearly the temperature of the steam in the main steam pipe. Further than this, the economy of the engine itself will be increased by the use of drier steam, since it is well known that there is less loss by condensation when dry steam is used than when wet steam is used.

Finally, there will be better lubrication in the steam engine cylinder, which will give a higher engine efficiency. For, if there is one thing above all others which will tend to spoil the cylinder lubrication, it is condensation. The hot water washes the oil from the surfaces which would otherwise be well lubricated, and the friction and wear are correspondingly increased. Increasing the rate of oil feeding only partially overcomes the difficulty and makes the oil bill greater.

The point is, therefore, to get rid of this moisture to the greatest possible extent, which may be accomplished either by superheating or by separation. In the present discussion, mechanical methods of separation only will be treated.

All mechanical devices for removing entrained moisture involve one or more of the following principles: First, separation by screens or meshes; second, decrease in velocity of the steam current; third, inertia; fourth, centrifugal force; fifth, baffle plates.

The first method is exemplified by the ordinary perforated dry pipe, by which the water particles are separated from the steam in passing through the holes. This form, however, is adapted only to internal separation; that is, separation occurring within the boiler itself. Consequently, it would remove only such moisture as would be present in the steam before it left the boiler, and would not catch that due to condensation in the steam main.

By decreasing the velocity of flow of a steam current, it is possible to remove a portion of its moisture, especially the larger globules. A current moving at a high velocity is capable of carrying with it water particles of considerable size. If, however, the velocity be suddenly decreased, the force of gravity may so assert itself as to draw out the heavier drops of moisture, even against the entraining influence of the current. In commercial separators this object is accomplished by enlarging the cross-sectional area of the pipe through which the steam must pass on its way to the engine. This is most conveniently done by placing a receiver of considerable volume in the pipe line, this receiver usually containing other devices for removing moisture. The amount of steam leaving the receiver is practically the same as that entering it. Furthermore, the quantity flowing in a given time is always $Q = A V$, in which Q is the cubic feet per minute, A is the area of the passage in square feet and V is the velocity in feet per minute. It is evident from this formula that if the area of the cross-section of the receiver is four times that of the steam pipe, the velocity of the steam in the receiver will be approximately one-fourth that in the pipe. And at this low velocity many of the heavier water particles will fall out of the current to the bottom of the receiver.

Inertia plays no small part in the action of many separators. It is a well-established law that no body can, of itself, set itself into motion, or bring itself to rest, or even change its direction of motion. These effects must be produced by some external force or forces. The application of this principle is of great value in the separation of moisture from steam. If the current of mingled water and steam, flowing along a straight pipe, is suddenly changed in its direction, as by a short bend, or by baffle plates placed directly in its path, a large amount of water may be removed. For the heavy water particles, by reason of their inertia, tend to move in a straight line, while the steam, being lighter, is readily deflected in any desired direction. The result is that the water strikes the walls or baffle plates and clings there, while the steam passes on.

In employing centrifugal force as a means of separating the moisture from the steam, the current is given a whirling or rotary motion. The result is that the water is thrown outward, lodging finally against the containing walls, from which it trickles and is drained off into suitable compartments.

The use of baffle plates of various forms

and varieties of construction is for the purpose of breaking up the steam current into numerous eddies and counter-currents, and also to change the direction of flow as frequently as possible. This enables the inertia of the water particles to be used to the best advantage and at the same time offers a greater area of surface on which the moisture may collect. These baffle plates are usually corrugated.

Fig. 1 illustrates a form of separator which is intended to be placed on a horizontal line of steam piping. The steam enters the separator at *A* and is deflected downward into the annular chamber be-

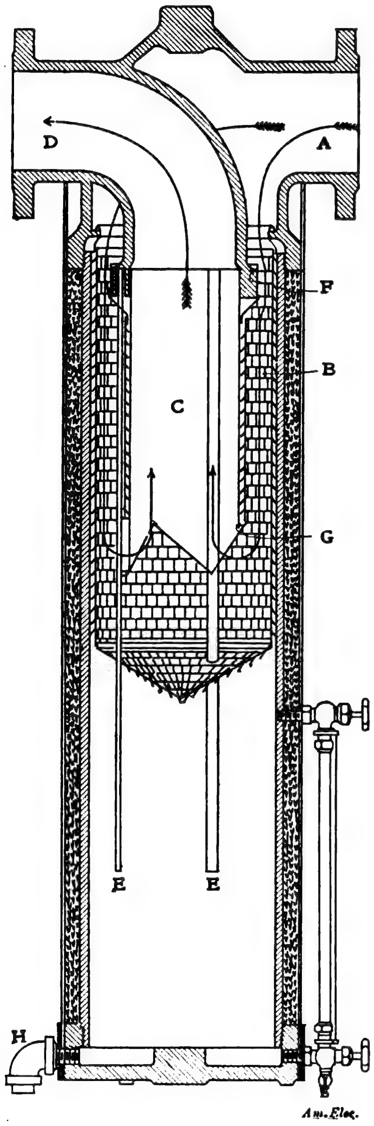

FIG. 1.

tween the central pipe and the perforated cylinder, *B*. The moisture is thus given a rapid downward motion. As it strikes the sides or bottom of the sieve, it goes through the perforations and drips to the bottom of the chamber. The short tongues of metal broken out in making the sieve are bent outward and downward, so that when the moisture has once passed through the sieve it cannot return so as to be caught up again by the steam current. The steam, thus liberated of much of its moisture, passes up the central pipe, *C*, and out at *D*. The pipes *E E* are drain pipes, which carry off the moisture which collects in the projecting lips, *F* and *G*, at the top and bottom, respectively, of the central pipe. It is evident that if this moisture were permitted to run down the sides of the pipe, *C*, and to drop from its lower end, there would be considerable likelihood of its being re-

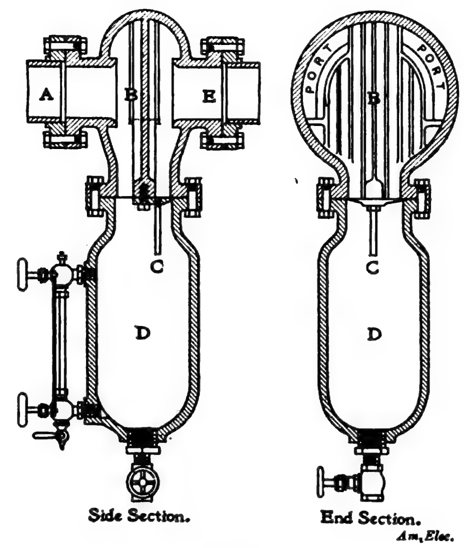

FIG. 2.

absorbed and carried along with the ascending steam current at that point. The water is drawn off through the outlet, *H*, at the bottom of the collecting chamber. The gauge glass is attached so as to enable the engineer to be certain at all times that the separator is fulfilling its duty, and that the water is being properly removed.

In Fig. 2 are shown two views, one a side section and the other an end section, of another well-known make of separator, designed for service on horizontal pipe lines. The steam, entering at *A*, meets a baffle plate, *B*, placed directly in its path. This baffle, as shown in the end section, is contained in an enlarged portion of the separator, and greatly exceeds the area of the steam pipe. On either side of this plate is a port leading to the discharge side of the separator, the sum of these two port

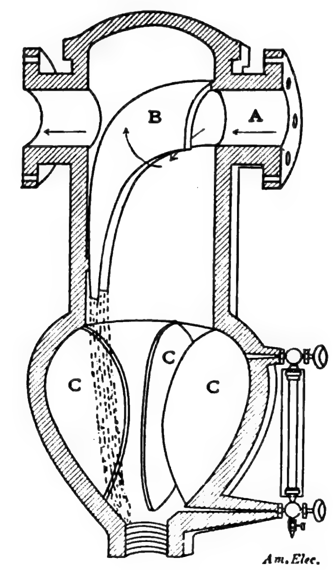

FIG. 3.

areas being likewise greater than that of the steam pipe. It will be seen that this type depends upon change of direction and the baffle plate to secure the desired result. The plate is ribbed vertically, so as to prevent the water from being carried laterally in the current, after having once impinged against the baffle, and also to carry it straight downward into the receiver at the bottom. The advantage claimed for placing the openings at the sides of the baffle plate instead of over it or underneath it, is that this arrangement prevents any possibility of entraining the water with the steam after it has collected on the baffle plate. The drip pipe, *C*, removes all condensation beyond the baffle discharging it into the chamber, *D*. It will be observed that this chamber is totally disconnected from the outlet, *E*, so that the steam cannot possibly pick up water from the settling well, *D*, and carry it out of the separator.

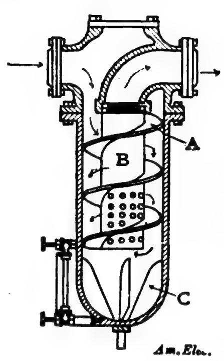

FIG. 4.

The type of separator illustrated by Fig. 3 depends solely upon decrease of velocity and change of direction. The steam current, entering at *A*, is quickly turned downward into the body of the separator by the curved partition, *B*, which serves to precipitate the moisture at the bottom of the reservoir. The vanes, *C*, *C*, *C*, are intended to destroy any rotary motion of the steam current, and also to prevent the water at the bottom of the chamber from being reentrained.

A separator depending largely upon the action of centrifugal force is shown in section in Fig. 4. Here the steam current is given a spiral motion by the vane, *A*, during which the moisture particles are thrown off against the outer wall, from which they trickle to the bottom of the separator. Some of the steam passes through the perforations in the central pipe, *B*, being further relieved of moisture in so doing, while the remainder passes into the bottom of

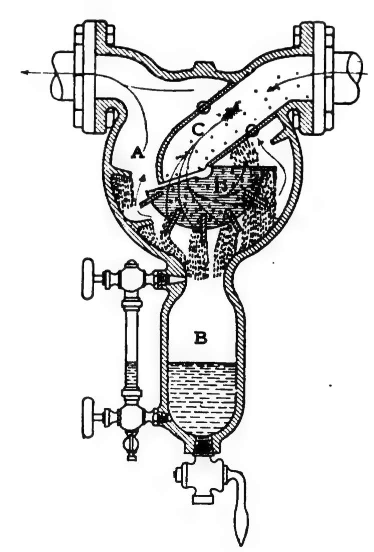

FIG. 5.

the separator, where its whirling motion is largely destroyed by the wings, *C*. It then rises through the pipe, *B*, to the outlet.

A type of steam separator combining all of the four methods of separation previously

mentioned is illustrated in Fig. 5. The device is a cast-iron chamber having practically two compartments, *A* and *B*. The steam is led into the larger chamber, *A*, by the pipe *C*, which is curved at its inner end so as to discharge the steam vertically downward. The inertia of the water then carries it down into the chamber, *B*. The large chamber, *A*, gives the necessary decrease of velocity, which will allow gravity to act upon the moisture, also. Centrifugal force is brought into play by passing the steam current between two curved vanes, one of which is shown at *D*. Finally, a number of baffle plates are placed along the lower edges of these vanes, to catch the moisture thrown out of the current by centrifugal force.

Separators intended for use on vertical lines of steam piping depend upon the same basic principles as the horizontal types already described, and differ only in the details of their construction.

A steam separator should be placed as close as possible to the engine, if the full benefit of separation is to be obtained. If it is placed at some intermediate point on the line, the condensation occurring between the separator and the cylinder will be carried into the engine. If it be placed near the boiler, it will remove only the initial moisture in the steam. Whereas, if placed close to the cylinder, it will take out moisture due either to priming or to later condensation. Ordinarily, the steam pipe to an engine is vertical just above the throttle valve, connecting with the main by a long bend and a horizontal. Manifestly, the nearest point of attachment of a horizontal separator would be in the horizontal pipe leading to the bend, and near the steam header. If a vertical separator is used, it can be placed directly above the throttle valve, in which position it will replace a portion of the pipe, and will act not only as a separator, but as a steam reservoir, as well.

ELECTRIC POWER IN MARBLE QUARRIES.

BY GEORGE E. WALSH.

The marble industry is comparatively young in this country, but in recent years its development in New England and parts of the West has been remarkable. The most extensive marble deposits have been found in Rutland County, Vt., where the resources and quality of the marble are such as to give to this section the name of the Carrara of America. The working of the American marble quarries has been accompanied by the development of tools and machinery for simplifying the work to an extent unknown elsewhere, and while the Italian quarries have been mined for centuries, the methods employed in getting out the marble and cutting and polishing it for the market are crude and primitive compared to those found in operation in the American marble regions.

The latest adaptation of power and machinery to the marble industry is the result of changing conditions. When the quarries were first opened, the range of work was kept within a narrow field, and a single steam plant would often serve to operate derricks, drills and channeling machines. Steam was conducted through pipes to the different machines, and air compressors were driven by the same power to the various places where pneumatic tools were employed. So long as the quarries were of moderate size, the hand and steam derricks, drills and locomotive cranes were sufficient to answer all purposes.

But marble quarrying is rapidly assuming an importance that makes a change of power distribution necessary, and some of the marble quarries have already reached such dimensions that steam power distribution has grown unwieldy and costly and electricity has entered to lessen cost. The smaller quarries may continue indefinitely in their dependence upon steam for operating their drills, cranes, locomotives, channeling machines, polishers and other tools; but the larger quarries are steadily installing electric motors for driving all sorts of labor-saving devices.

Owing to the enormous weight of some of the blocks of marble that are cut and dressed for shipment, such as for obelisks, mausoleums, statuary groups and so on, the derricks and cranes are the most important implements, and modern powerful electric gantry cranes are now installed in most of the larger quarries. One of the most noteworthy of these electric cranes has been in operation for some time at Proctor. Vt. This is a huge, five-motor, electric traveling gantry crane and it displaced ten of the old steam power derricks. It can be operated by one man, and, therefore, saves as much in labor as it does in efficiency. The gantry travels 800 feet, but the distance can be increased indefinitely as the quarry extends. Its maximum capacity is 50 tons, and the blocks of marble can be lifted to a height of 35 feet. This crane was installed chiefly for loading cars; the trains pass directly under the crane, and as the bridge on which the crane travels is 160 feet long it has a wide field of operation.

Smaller three-motor electric traveling cranes on steel railways are also employed. Several ten-ton electric cranes are used for lifting the marble blocks from the quarry and for handling them in the cutting and polishing department. The old powerful boom derricks driven by steam power are still in operation, but their use is gradually diminishing since the advent of the electric cranes, and they are employed now chiefly in isolated parts of the quarry for lifting the blocks from the beds after being cut out.

Portable or locomotive cranes are further making the boom derricks unprofitable; they can travel from one part of the quarry to another, and load blocks directly from the beds to the cars. Both electric drills and channeling machines are now in use in the West Rutland and Proctor quarries, and careful data are being compiled to ascertain the relative cost of the two types. The channeling machines are the most important in a marble quarry, for it is impossible to drill holes in marble and then use high explosives. The blocks must be cut out carefully and lifted without cracking them.

It has only been in the last year or two that electric channeling machines were used at all. But they have given so much satisfaction that their number is being rapidly increased. The new type of electric machine cuts a channel on either side of it from four to ten feet deep and less than two inches wide, whereas the steam type of channeling machine cut but one channel at a time. A single electric motor mounted on the new machine and traveling with it operates the cutting implements and also drives the traction gear of the machine.

Electrically operated chisels, "sand saws," buffers, etc., are also used in the Vermont quarries; in fact, nearly every practical means of reducing hand labor by means of electricity has been adopted. More than $5,000,000 is invested in the quarry machinery and other equipment, a large portion of which is electrical.

THE PERFORMANCE OF DIFFERENT TYPES OF ELECTROMAGNET.

BY CHARLES R. UNDERHILL.

The electromagnet is used in so many

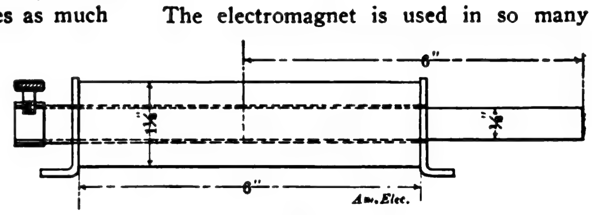

FIG. 1.

different ways, and electromagnetic phenomena taken advantage of to such an extent, that a complete classification of the numerous types would be rather difficult. However, the subject may be treated from a general standpoint, and in this article it is intended to show the general relations between the types in common use. The common types of electromagnet windings were discussed in a former article.*

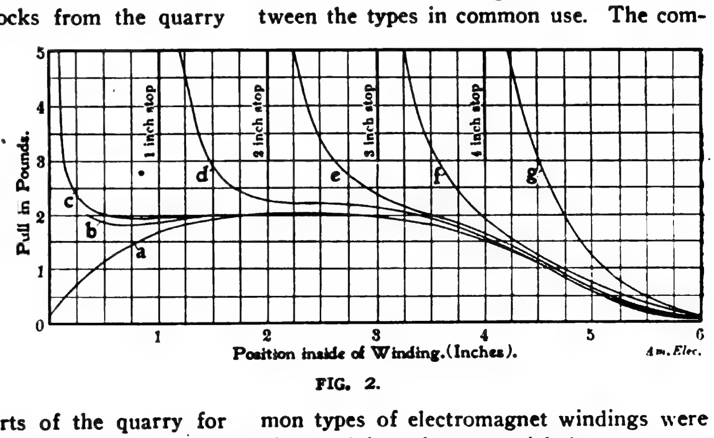

FIG. 2.

If one end of an iron core be placed within the field of a solenoid, it will become a magnet, and mutual attraction will result between the field of the solenoid and the iron core, or plunger, as it is called. Elec-

*AMERICAN ELECTRICIAN, May, 1905.

tromagnets of this type are used where a long range of action is desired. In Fig. 1 is shown a coil-and-plunger arranged for experimental purposes, and Fig. 2 is a chart showing the results of tests made with it. In all cases the ampere-turns were 6300.

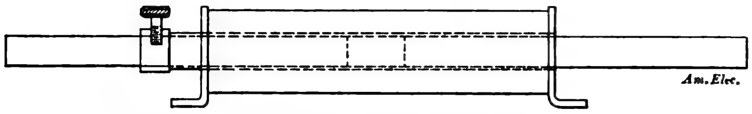

FIG. 3.

Curve *a* is due to the attraction of this coil-and-plunger, the distances being measured from the left end of the plunger to the left end of the winding.

By clamping a rod of iron inside the winding as in Fig. 3, a different effect is obtained. The magnet is now a "stopped" solenoid, or stopped coil-and-plunger.

Curve *b*, in Fig. 2, was obtained from the same coil as before, but with a stop 1 inch long, its right-hand end being flush with the left-hand end of the winding. Curve *c* is from a test with a stop of approximately the same length as the plunger, and with its right-hand end flush with the left-hand end of the winding, as in the case of curve *b*. It is obvious that a small piece of iron at the end of the winding is beneficial, as it prevents the pull from falling off at that end, thereby increasing the effective range of the solenoid. It should be noted that all parts of the frame of this experimental solenoid were of non-magnetic material, the only ferric portions being the plunger and stop.

The curves, *d*, *e*, *f* and *g*, are due to the end of the stop being inserted in the coil 1 inch, 2 inches, 3 inches and 4 inches, respectively. An examination of Fig. 2 shows that curves *c*, *d*, *e*, etc., are the result of the attraction between the plunger and the stop plus the solenoid effect.

A simple solenoid with an iron jacket or frame, commonly called an "iron-clad" solenoid, confines the field within the limits of the frame, thereby raising the curve at the right end, or mouth of the winding, also. Fig. 4 is the result of a test of the iron-clad solenoid in Fig. 5.

An iron-clad stopped solenoid is commonly called a plunger electromagnet; the form shown in Fig. 6 may be considered a plunger electromagnet with a stop practically flush with the left end of the winding.

Fig. 7 shows the difference between the tests of this electromagnet with and without the iron frame. The curve due to the test with the iron frame is marked "iron-clad solenoid," and the test without the frame is designated "simple solenoid." The increased effective range is plainly shown here.

The curves marked "plunger electromagnet" are due to the plunger electromagnets in Figs. 8 and 9. These curves should be compared with curve *f* in Fig. 2. On account of the iron frame, the pulls near the mouth of the coil will be greater than with the simple stopped solenoid.

Tapering the end of the plunger and countersinking the stop have the effect of increasing the pull for long ranges, owing

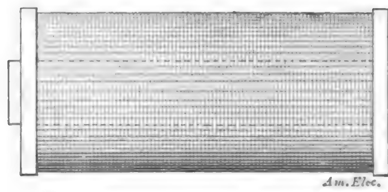

FIG. 14.

to the increased attracting surfaces, but the pull is less as the plunger passes within the stop, owing to the line of attraction being at an angle to the direction of the required pull. An extreme case of the tapered plunger and countersunk stop is shown in Fig. 10 where the taper is nearly as long as the winding.

Fig. 11 shows the result of a test of the plunger electromagnet in Fig. 8 with a stop 2½ inches long. As the test was made, the current in amperes and the pull was noted, and since the number of turns in the winding were known, the ampere-turns were easily calculated, and the curves plotted for each length of air gap. Fig. 12 is plotted from Fig. 11 by taking points vertically on the ordinate for 10,000 ampere-turns, 15,000 ampere-turns, etc., where they intersect the curves representing the different lengths of air gaps.

Returning to the stopped solenoid in Fig. 3, the stop was set at various distances, and the pull then noted for 0.035 inch gaps be-

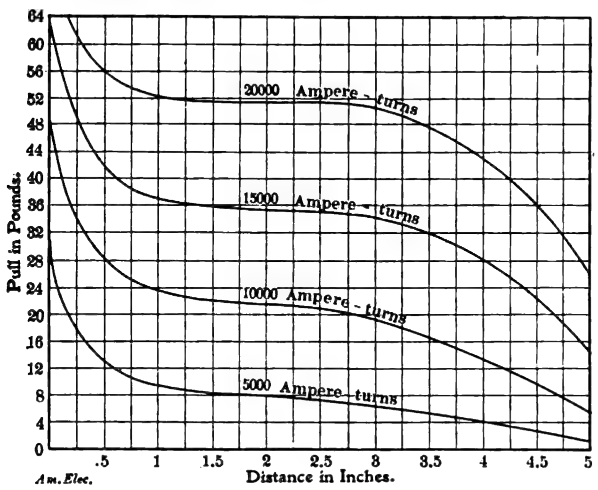

FIG. 4.

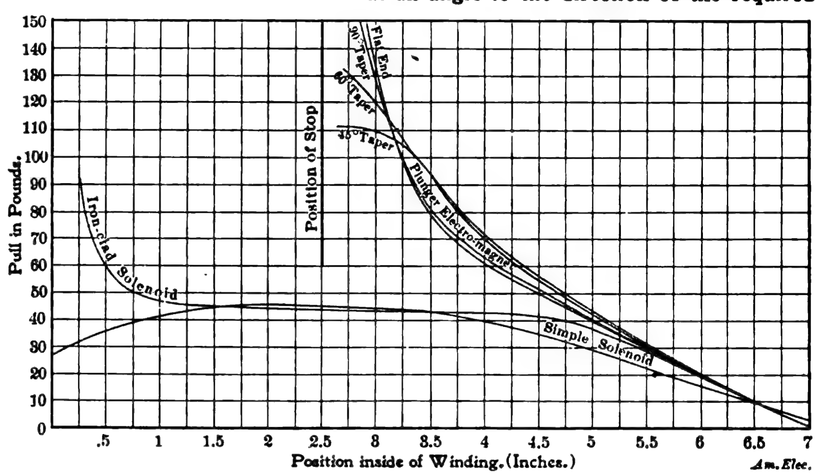

FIG. 7.

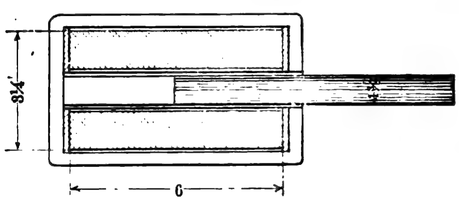

FIG. 5.

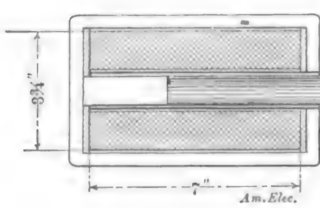

FIG. 6.

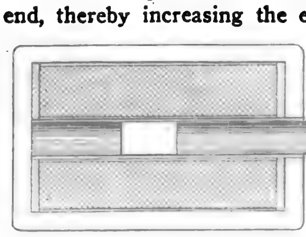

FIG. 8.

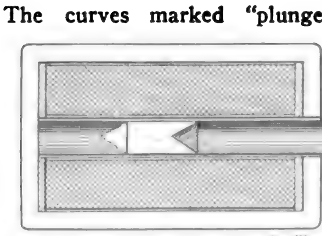

FIG. 9.

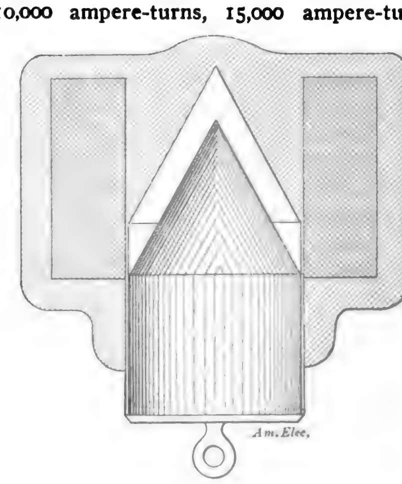

FIG. 10.

tween the plunger and the stop. The curve in Fig. 13 shows the result of this test.

In Fig. 14 is shown a bar electromagnet, which is simply a solenoid with the plunger rigidly fastened within it, so that there can be no motion between them. Therefore, the only function of this type of electromagnet is to attract other magnetic materials to it. If the plunger were clamped firmly inside the solenoid in Fig. 1, this would then be a bar electromagnet.

Now the stopped solenoid in Fig. 3 may be considered as a bar electromagnet with its armature, the plunger, projecting into the winding. It is therefore evident that the bar electromagnet in Fig. 14 is not so efficient as the stopped solenoid (or extreme case for a bar electromagnet), in Fig. 3, as reference to Fig. 13 indicates. Thus, where the working air gap is 1½ inches within the winding, the pull is 25 pounds, while for the same air gap at the mouth o1 the winding, the pull is only 13½ pounds, or about one-half the pull within the winding.

It is also evident that the pull continues to fall off as the proportion of air gap outside of the winding increases. The reason for this is, that the lines leak back on the outside of the winding to the other end of the winding, and therefore do not pass through the working air gap as they would be compelled to do were the gap inside of the winding. This reasoning applies to the horseshoe type of electromagnet, which is a bar electromagnet so bent as to bring its two poles near together; although the strength is comparatively great when the iron armature is in actual contact, or very close to the pole pieces of the magnet, the attraction of the armature by the poles is very weak when the air gap is comparatively small, owing to the leakage back of the armature, from end to end of the cores of the electromagnet. Fig. 15 shows the re-

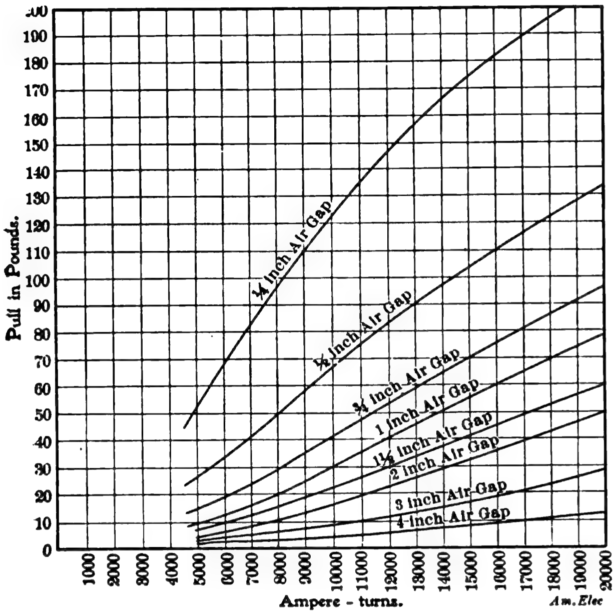

FIG. 11.

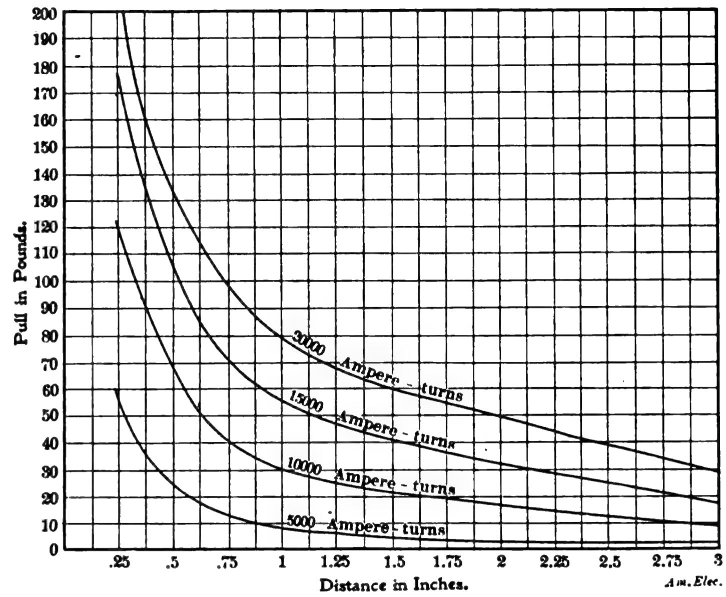

FIG. 12.

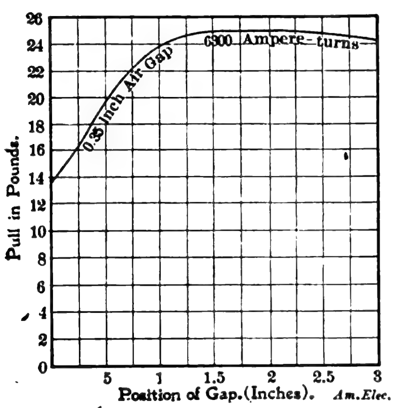

FIG. 13.

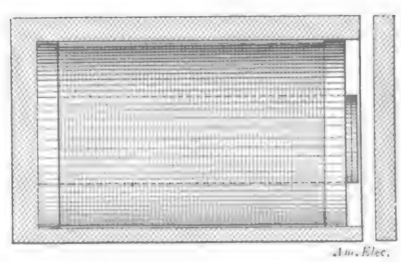

FIG. 18.

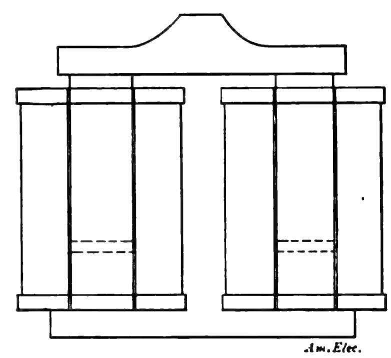

FIG. 19.

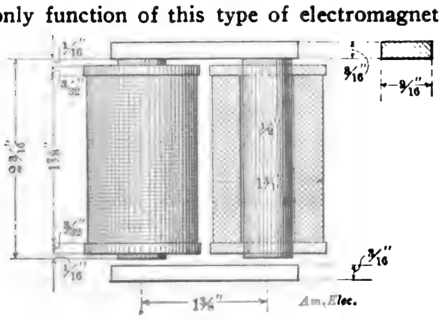

FIG. 16.

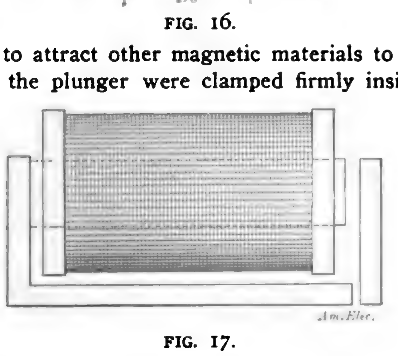

FIG. 17.

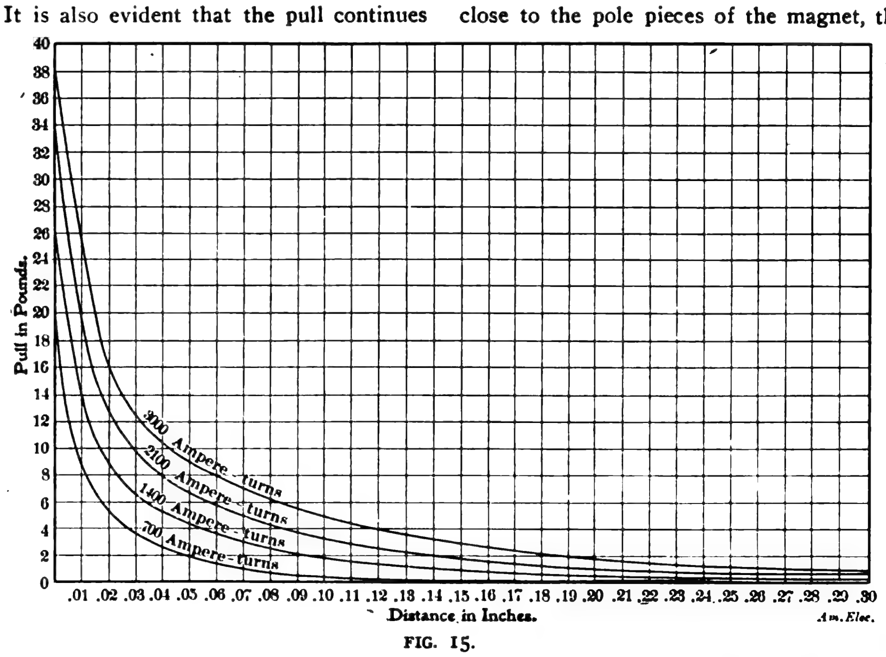

FIG. 15.

sult of a test of the practical horseshoe electromagnet in Fig. 16. The horseshoe electromagnet has many modifications, such as the club-footed electromagnet in Fig. 17, the iron-clad electromagnet in Fig. 18, etc.

From the foregoing it is evident that the bar electromagnet (Fig. 14) or the horseshoe electromagnet are not well adapted for long range work. They are, however, indispensable where rapid action is desired.

It is obvious that the solenoid and plunger electromagnet may have two coils and two plungers as well as one. Fig. 19 shows a two-coil plunger electromagnet, which is really a horseshoe electromagnet with its ordinary armature fastened to the ends of the cores, the cores then being separated at or near the centre of the windings. In this type each core serves as a return circuit for the other core.

Plunger electromagnets and solenoids are adapted for use where a strong pull is required over a considerable range, such as for operating brakes for hoisting motors, electric elevator controllers, railway switches, etc., while electromagnets of the horseshoe type are used for signaling purposes, as in telegraphy and telephony, and also for lifting magnetic bodies in close contact with their pole-pieces.

American Types of Control Apparatus for Direct Current Motors.

BY LAURENCE B. MATHER.

Motor-controlling apparatus may be divided into two general classes, one for merely starting a motor and bringing it up to normal running speed, and the other for starting the machine and also regulating its rate of speed. The former class includes both manually and electromagnetically operated mechanism, while the latter, excepting in very special cases, is restricted to purely manual operation. Simple motor-starting apparatus of the modern manually operated type is always provided with automatic means for restoring the movable member to the "off" or starting position in the event of the failure of the supply current. The apparatus itself comprises a series of resistance coils which are put in series with the armature when the circuit is first closed and then gradually cut out by means of a brush mounted on the free end of a swinging arm and arranged to sweep over a row of stationary contacts connected to the resistance coils. This type is familiar to everyone at all experienced in motor operation. The automatic release consists of a small magnet which is energized as long as the circuit is intact and which holds the starting arm in the full-speed position; cessation of the supply current de-energizes the magnet, of course, releasing the arm, and a spring returns it to the starting position.

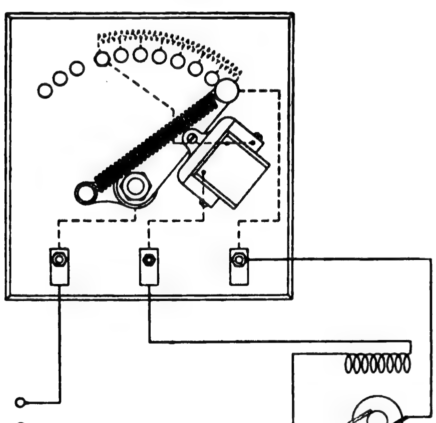

FIG. 1.—FIELD CIRCUIT ALWAYS CLOSED.

Fig. 1 shows a common arrangement of the release magnet and the other parts of the starter. The release magnet is connected in series with the shunt field magnet winding of the motor and the starting resistance when the arm is in the full-speed position, as shown in the diagram; the object of this method of connection is to keep the field circuit always closed. At the first step of the starting arm, the shunt field and release magnet are excited and current is admitted to the armature through the complete starting resistance, and as the resistance is gradually cut out of the armature circuit it is cut into the field circuit;

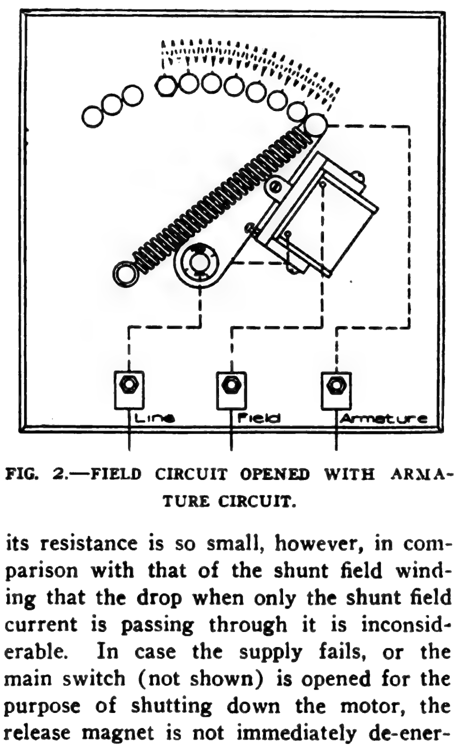

FIG. 2.—FIELD CIRCUIT OPENED WITH ARMATURE CIRCUIT.

its resistance is so small, however, in comparison with that of the shunt field winding that the drop when only the shunt field current is passing through it is inconsiderable. In case the supply fails, or the main switch (not shown) is opened for the purpose of shutting down the motor, the release magnet is not immediately de-energized because the momentum of the armature and sluggish decay of the field magnetism convert the machine into a dynamo of rapidly decreasing e.m.f., and it keeps the release magnet energized for several seconds in some cases; when the armature e.m.f. diminishes sufficiently to reduce the current in the release magnet below the "sticking" point, it lets go and the arm is thrown back to the starting position; but as the release magnet is connected to one terminal of the starting resistance and the free armature brush is connected to the other, there remains a closed circuit through the field winding, armature, starting resistance and release magnet, so that any remaining magnetism in the field magnet has an opportunity to discharge.

The arrangement shown in Fig. 2 was formerly used exclusively, but it has been superseded in many cases by the connection shown in Fig. 1, which is usually preferable because large motor field magnets do not always lose their magnetism sufficiently, before the release magnet lets go, to avoid an objectionable inductive flash when the swinging arm opens the field circuit by leaving the first starting button as it is thrown back to zero by the spring.

Fig. 3 shows still another method of connecting up the release magnet; here, it is connected across the line in series with the starting resistance when the arm is in the running position, as shown in the diagram. This arrangement has the obvious advantage that the magnet is sure to receive full excitation regardless of the character of the shunt field winding of the motor, while in the other cases a shunt field winding of unusually high resistance might take insufficient current to make the release magnet hold the starting arm reliably; in practice, however, this is a rather remote contin-

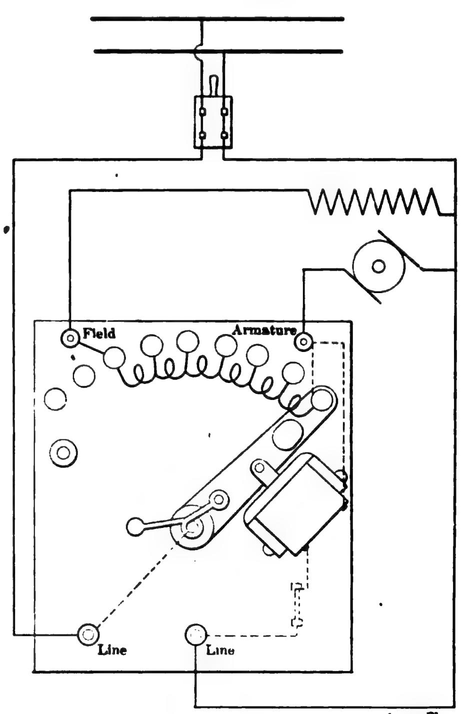

FIG. 3.—FIELD CIRCUIT ALWAYS CLOSED; RELEASE MAGNET ACROSS LINE.

gency, since the release magnet can readily be designed for reliable operation with a current smaller than the field winding can possibly be excited with, and still have radiating surface sufficient to enable it to carry the largest current that any normal

motor field will require. The arrangement of Fig. 3 has the real advantage, however, of being universal so far as the type of the motor field winding is concerned; it can be used with a series, shunt or compound-wound motor without any changes whatever in its own circuits or parts; the diagram shows it applied to a shunt-wound motor, and it is evident that erasing the

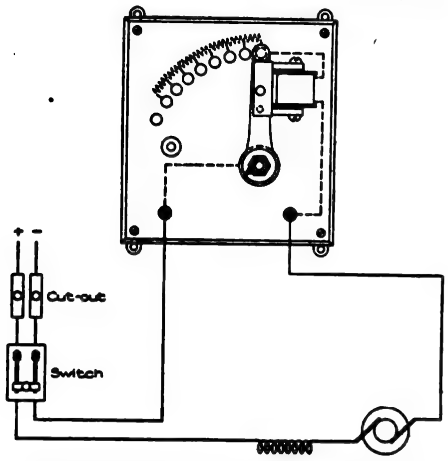

FIG. 4.—USUAL CONNECTIONS FOR SERIES MOTOR.

shunt-field winding and connections from the diagram and inserting a field winding in the armature circuit would make it ap-

FIG. 5.—CUTLER-HAMMER STARTING RHEOSTAT.

ply to a series motor, while inserting the series field without disturbing the shunt-field winding would show it as applied to a compound-wound motor.

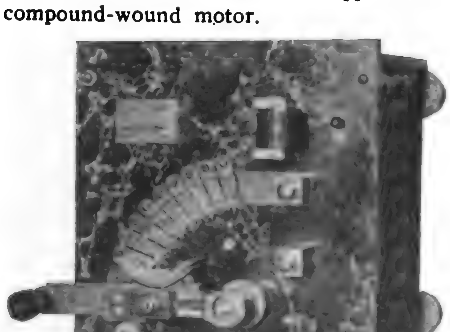

FIG. 6.—CUTLER-HAMMER HEAVY-DUTY STARTER.

For series motors, the common arrangement is as shown in Fig. 4, which requires no explanation. In this case, it is not so important to maintain the field circuit closed after the motor is disconnected from the supply circuit because there are not nearly so many turns in the winding and the inductive e.m.f. due to the discharge of the

FIG. 7.—GENERAL ELECTRIC STARTING BOX.

field magnetism is not high enough to do any damage.

The Cutler - Hammer Manufacturing

FIG. 8.—DOUBLE-CONTACT STARTING BOX.

Company, Milwaukee, for shunt-wound motors uses the method of connection shown by Fig. 1, and its starting box is shown complete by Fig. 5. The starting arm carries near the handle a small bar of iron which comes into alignment with the poles of the single-core release magnet at the right-hand side of the box when the arm reaches the running position. For larger sizes of motor, the starting box is modified slightly to the form shown by Fig. 6. The modification consists in adding a laminated contact brush which, when the arm has been carried around to the running position, bridges two heavy block contacts located beneath the release magnet and thereby short-circuits the starting contacts entirely and eliminates danger of trouble from insufficient contact area in those parts.

In smaller sizes, the General Electric Company uses the starter shown in Fig. 7, which is very similar to that shown in Fig. 5. The chief difference is that a helical spring is employed to restore the starting arm to the "off" position when it is released by the magnet, while in the Cutler-Hammer box the spring is a spiral, coiled about the pivot stud. The method of connecting the release magnet is that shown by Fig. 1. For larger sizes the G. E. starter is made in the form shown by Fig. 8, the internal connections being shown by Fig. 9. The starting resistance is divided into a larger number of steps by the addition of another row of contacts interconnected as indicated. The swinging arm carries an auxiliary finger which is pivoted to the end of the arm and makes a quick snap break when the arm passes the upper button of the right-hand row on being thrown back to "off."

In the largest sizes, the General Electric Company uses the substantial form of starter shown in Fig. 10, in which the traveling brush is of laminated construction like the metal contact bridge of an automatic circuit-breaker, the stationary contacts are trapezoidal plates instead of round

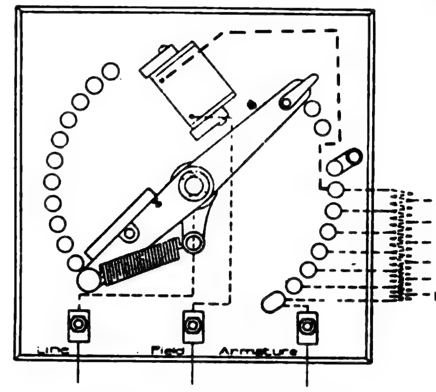

FIG. 9.—DIAGRAM FOR FIG. 8.

buttons, and the release magnet holds the starting arm at "full on" by means of a latch instead of direct magnetic attraction. By reference to the diagram, Fig. 11, and close inspection of Fig. 10, it will be noticed that the swinging arm carries a traveling brush at each end and that only one end of each of these brushes rests on the stationary contacts during the movement of the arm, but when it reaches the running position both ends of both brushes rest on the last contact plates of the two rows, which are extended for that purpose; this gives ample contact surface to carry the full running current without entailing the extra friction that would attend the use of the full contact surface during manipulation of the arm. Fig. 11-A is a detail of the release magnet, its armature and the latch finger on the end of the swinging arm.

FIG. 10.—G. E. HEAVY-DUTY STARTER.

The next step in the simple motor starter line is the addition of an automatic device to open the motor circuit in the event of an overload. The Ward Leonard Electric Company, Bronxville, N. Y., uses an auto-

matic circuit-breaker which operates on exactly the same principle as the apparatus used on switchboards for protecting station apparatus, and interlocks with the starting arm. Fig. 12 illustrates the apparatus. The no-voltage release magnet is shown at the right of the face-plate, as in some of the previous cases, and the circuit-breaker solenoid is located at the lower left-hand part under the auxiliary arm. This arm is pivoted concentrically with the starting arm, and a spiral spring around the pivot

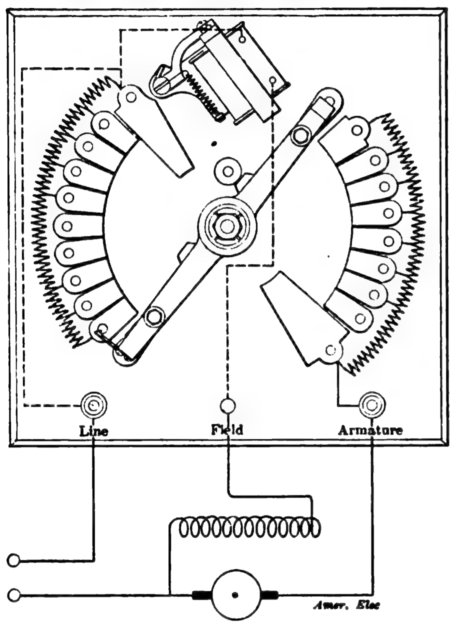

FIG. 11.—DIAGRAM FOR FIG. 10.

post is attached at one end to the starting arm and at the other to the circuit-breaker or auxiliary arm. The right-hand end of the latter carries a brush which bridges two stationary blocks and thereby closes the main motor circuit when the arm is in the normal position shown; in that position it is held at the left-hand end by a latch which is tripped by the solenoid when the load passes the point for which it is set. A lug on the starting arm engages the auxiliary arm when the movement is from right

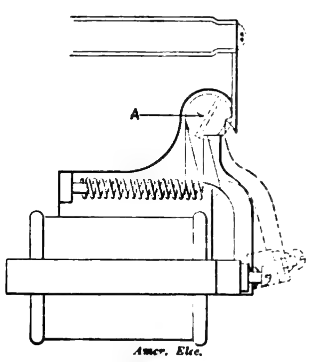

FIG. 11-A.

to left, but when the starting arm is moved around to the running position the circuit-breaker arm is left free to open if it should be released by the solenoid.

When the circuit-breaker lets go with the starting arm in the full running position, the spring throws the auxiliary arm clockwise until it takes up against the lug on the starting arm; this leaves the latter arm still in the full "on" position, but the motor cannot be put in circuit with it in that position except maliciously and by taking the trouble to hold the arm against the release magnet and resetting the circuit-breaker arm with the other hand. There being no handle on the latter arm, there is no normal incentive to do this; the natural

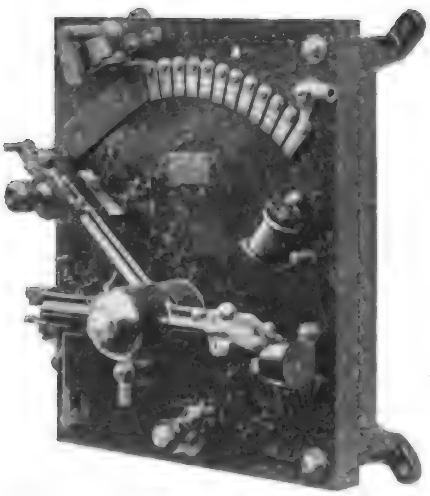

FIG. 12.—WARD-LEONARD STARTER WITH OVERLOAD CIRCUIT-BREAKER.

procedure is to set the circuit-breaker by means of the handle on the starting arm, moving the latter back to its "off" position and thereby restoring the auxiliary arm to its latch. The connections of the starting resistance and release magnet are as shown in Fig. 3; the circuit-breaker solenoid is connected in series with the motor, of course.

As Fig. 12 shows with fair distinctness,

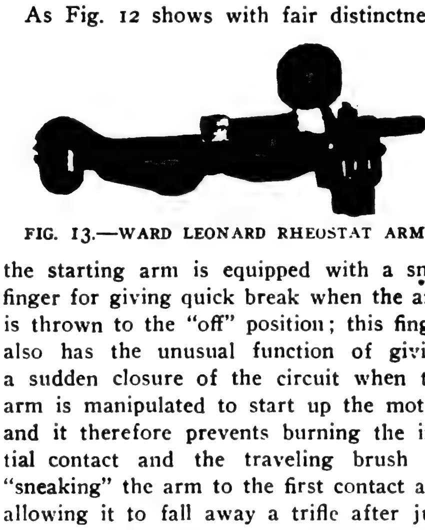

FIG. 13.—WARD LEONARD RHEOSTAT ARM.

the starting arm is equipped with a snap finger for giving quick break when the arm is thrown to the "off" position; this finger also has the unusual function of giving a sudden closure of the circuit when the arm is manipulated to start up the motor, and it therefore prevents burning the initial contact and the traveling brush by "sneaking" the arm to the first contact and allowing it to fall away a trifle after just

FIG. 14.—G. E. STARTER WITH NO-VOLTAGE AND OVERLOAD RELEASE.

touching. The finger is pivoted to the end of the arm and carries a pin which strikes the projecting lug on the post near the first stationary contact when the arm is moved toward that contact and holds the finger out of engagement with its co-operating stationary contact until just before the main brush reaches the first regular contact plate, when it slips past and is thrown by a spring into rubbing contact with a stationary brush. The quick break on the reverse movement is accomplished in a similar manner. Fig. 13 illustrates the construction of the traveling brush on the arm; it consists of several skates on the ends of plungers socketed in the end of the starting arm and pressed downward on the stationary contact plates by individual

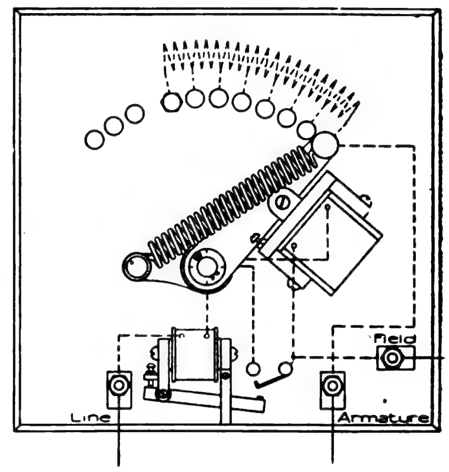

FIG. 15.—DIAGRAM FOR FIG. 14.

springs. The skates are connected to the main part of the arm by means of individual flexible cords so as to obviate the uncertainty and liability to arcing and burning in the sockets which would attend reliance on the contact between the plungers and their housing.

Fig. 14 shows the General Electric type of combined no-voltage and overload release, and Fig. 15 is the corresponding diagram of connections. The overload release consists of an extra magnet in series with the motor and having its armature arranged to short-circuit the no-voltage

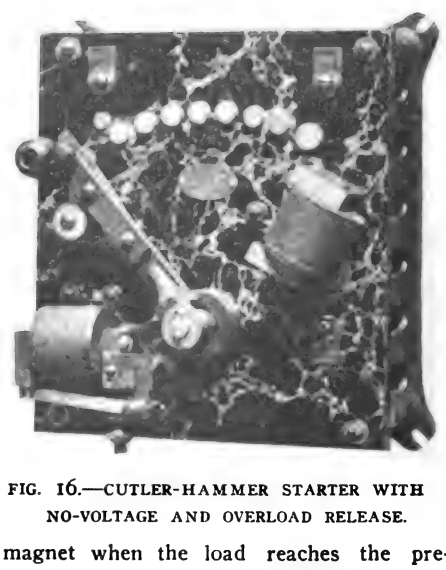

FIG. 16.—CUTLER-HAMMER STARTER WITH NO-VOLTAGE AND OVERLOAD RELEASE.

magnet when the load reaches the predetermined point; in this diagram the no-voltage release magnet is shown connected as in Fig. 2, but the method of connection shown in Fig. 1 is also employed.

Fig. 16 shows the Cutler-Hammer starting box with no-voltage and overload release, the latter feature being arranged as shown in the diagram, Fig. 15. This arrangement is recommended for protection from moderate overloads, but not for

short-circuits or sudden and heavy overloads; it furnishes an excellent means of determining how much current the motor is taking without making an ammeter test, the magnet armature being adjustable to respond to different currents and the short-circuiting connection being rendered inoperative by removing a single screw.

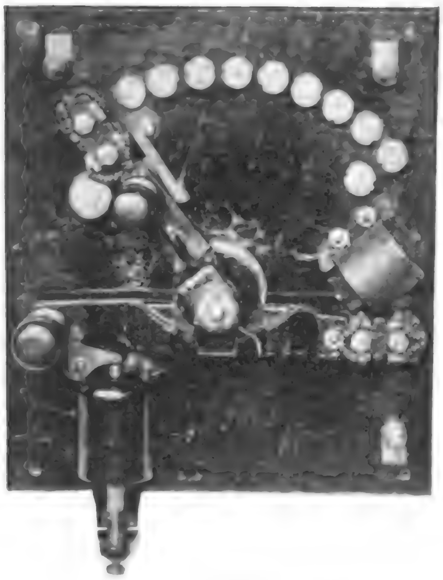

FIG. 17.—CUTLER-HAMMER STARTER WITH OVERLOAD CIRCUIT-BREAKER.

For universal protection against overloads, the circuit-breaker attachment illustrated in Fig. 17 is employed. This mechanism is very much like that already described and illustrated by Fig. 12. When the circuit-breaker lever is released by the solenoid and latch, it is thrown against the starting lever and automatically locked with it so that it cannot be reset without carrying the starting lever back to the "off" position.

The Cutler-Hammer starting box for series-wound motors has the release magnet connected in series with a resistance coil directly across the line instead of in series with the motor, as in Fig. 4.

Fig. 18 illustrates the Cutler-Hammer motor-starter for heavy duty and large motors and Fig. 19 is a diagrammatic view of this type applied to a shunt-wound motor.

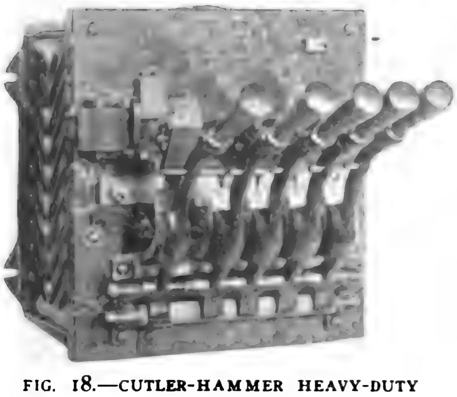

FIG. 18.—CUTLER-HAMMER HEAVY-DUTY SWITCH STARTER.

tor. The starting resistance is divided into a smaller number of sections, the absence of sliding contacts rendering finer division unnecessary. The apparatus consists of a series of switches having laminated butt contacts like those of an automatic circuit-breaker and arranged to short-circuit the sections of the starting resistance. The first switch (on the extreme left) is held in by the release magnet after it has been closed by hand; the others are held closed by latches and are normally prevented from closing by stops, these being arranged so that as each switch is closed it removes the stop from the path of the next switch. The latches are similarly arranged, but in reverse order; thus, in starting, the extreme left-hand switch is closed first, and this closes the motor-armature circuit to the supply line through all of the starting resistance, and closes the field circuit direct; it also removes the stop from the path of the second switch, which is next closed, cutting out a section of the starting resistance; the other switches are closed successively, the last one putting the armature directly across the line, as usual. To shut down the motor, the main switch (shown in the diagram) is opened, cutting off the supply of current to the motor and the release magnet, and the latter releases the first switch. This is equipped with an auxiliary carbon break, and when it opens this takes whatever flash there may

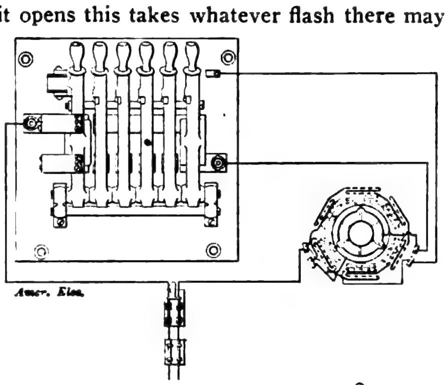

FIG. 19.—DIAGRAM FOR FIG. 18.

be. The opening of the first switch trips the latch of the second one, and that one falls open, tripping the latch of the third one, and so on. The apparatus should never be left with the motor running until all the switches have been closed, and this type is subject to the slight disadvantage that it is possible to leave it in that condition, whereas the older type already described cannot be made to keep the motor in circuit unless the arm is carried all the way to the "full-on" position.

Starting and Regulating Hand Rheostats.

The development of the variable-speed motor regulated by field variation alone or in combination with some armature resistance has led to the perfection of a very convenient form of starting box, including also means for regulating the field strength of the motor. Fig. 20 illustrates the Cutler-Hammer apparatus of this type with both no-voltage and overload release, and Fig. 21 is the corresponding diagram of connections. Two arms are pivoted on the same post, the one nearest the face-plate being the starting lever and the other, having the handle mounted on it, being the speed-regulating lever. The starting lever is moved over to the running position by means of the handle on the speed lever, the latter engaging with the pin in the starting arm near the pivot; when the starting arm reaches the first contact in the armature circuit, it also makes contact with the sector beneath the row of starting contact buttons and thereby short-circuits the field-regulating resistance, giving maximum field; when it reaches the full-speed running position, it

FIG. 20.—CUTLER-HAMMER COMBINED STARTER AND REGULATOR.

leaves the sector and releases the field resistance to the control of the other lever, which may then be moved to any position within its travel. This latter lever connects with the upper row of buttons, which are tapped to the field regulating resistance, and is capable of varying the field strength in the ratio of 2:1 ordinarily, but the rheostat is also built for 3 to 1 and 4 to 1 ranges when so ordered. When the no-voltage release magnet lets go, the starting arm is thrown back to "off" as usual, and carries with it the field-regu-

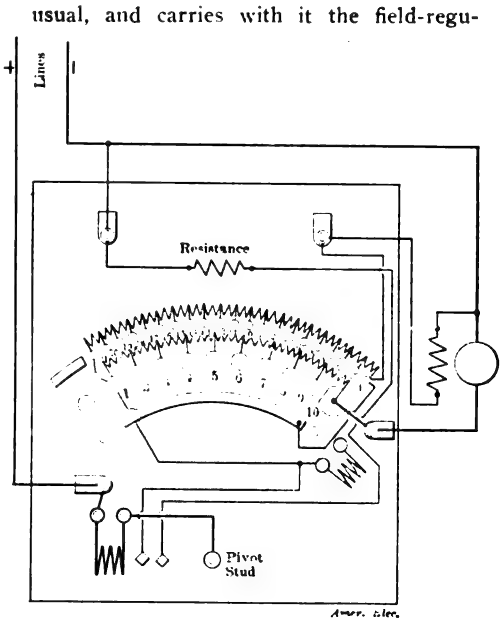

FIG. 21.—DIAGRAM FOR FIG. 20.

lating arm. The release magnet is connected in series with a resistance coil across the line, as shown in the diagram, the variation of field current making it undesirable to put it in the field circuit. The overload release is of the type already described in connection with Fig. 16. This style of starter and regulator is also built

without the overload release, but not without the no-voltage release.

The Ward Leonard combined starter and field regulator is shown in its simplest form by Fig. 22, with no-voltage release and overload circuit-breaker. The starting arrangement, circuit-breaker and release

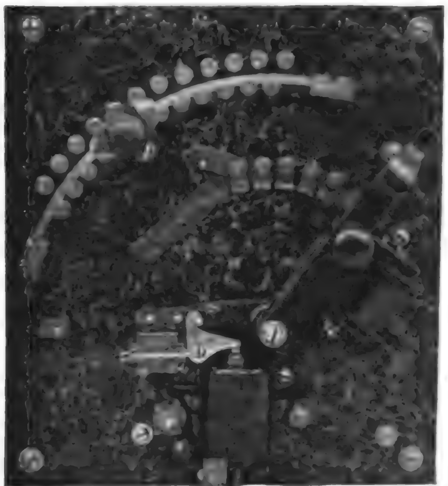

FIG. 22.—WARD LEONARD COMBINED STARTER AND REGULATOR; DOUBLE RELEASE.

magnet are exactly like those described in connection with the Ward Leonard starter. The field strength is regulated by means of the slider and row of contacts shown above the starting contacts, and the starting arm is provided with an extension which carries the speed-regulating slider back to the point of maximum field strength when the arm is thrown to "off" by its spring or by its handle after the opening of the circuit-breaker. This outfit is also built without the overload circuit-breaker.

Fig. 23 shows the Ward Leonard speed regulator for motors driving fans or blowers or in other similar service, where regulation by armature resistance is practical. This device has two arms concentrically pivoted, one of them being held by the no-voltage release magnet while operating con-

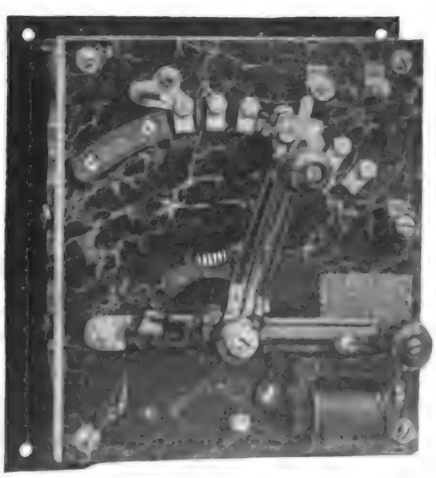

FIG. 23.—WARD LEONARD SPEED REGULATOR; AUTOMATIC RELEASE.

ditions prevail and thrown to the other extreme of its travel by a spring when released by the magnet. The other arm starts and regulates the speed of the motor by varying the resistance in the armature circuit, and it is free to remain in any position in which it may be set. When the spring-controlled arm is released by the magnet, it is drawn over to the left by its spring and carries with it the regulating arm; the latter is equipped with the rapid make and break finger described in connection with the Ward Leonard starting box. This regulator is also built with an interlocking overload circuit-breaker like that used on the ordinary starting boxes of the Ward Leonard Company.

The Ward Leonard controller shown in Fig. 24 combines the functions of the two just described, namely, speed regulation by mean of armature resistance, field variation, and the starting up of the motor from a standstill. It has two operating arms, like the one last described, one of which is held in restraint by the no-voltage release magnet and returned to zero by a spring when released, and the other serves to start and control the speed of the motor. In starting, the right-hand arm is thrown over until the magnet armature rests against the magnet poles, and the other arm is then moved to the first contact plate to start the motor; the first five

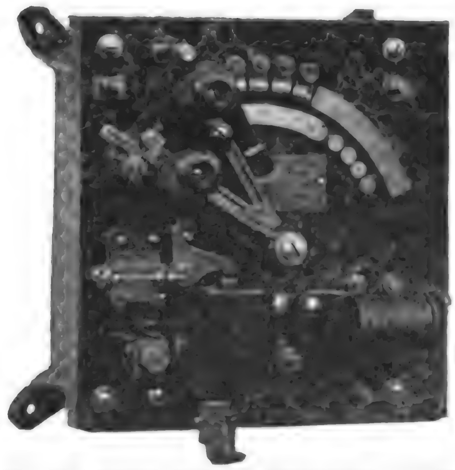

FIG. 24.—WARD LEONARD REGULATOR; AUTOMATIC RELEASE AND CIRCUIT-BREAKER.

contact plates control the speed by resistance in the armature and the last four cut resistance into the shunt-field circuit; the arm remains wherever it is set, of course. To shut down, the main switch (not shown) is opened, and the no-voltage magnet releases the spring-controlled arm, which is thrown back, carrying the speed-regulating arm with it to the "off" position. The engraving shows the apparatus equipped with the overload interlocking circuit-breaker already described, but it is also built without this feature.

Fig. 25 illustrates the Cutler-Hammer compound speed-regulating rheostat. It is of the single-lever type, with no-voltage and overload release and automatic return to the "off" position when released. The swinging arm is held in any position to which it may be adjusted by means of a pawl mounted on the armature of the release magnet and a ratchet mounted on the arm. The first eleven steps vary the resistance in the armature circuit and the last four control that in the field circuit. The no-voltage release magnet is connected in series with the field winding, its duty being so light that the smallest practical field current will operate it; when its armature is attracted, the spring pawl is drawn into mesh with the ratchet teeth in the edge of the disc of the starting and regulating arm, and these teeth are located at the proper points too hold the arm

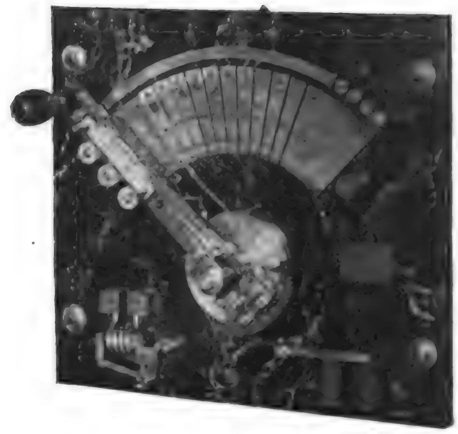

FIG. 25.—CUTLER-HAMMER REGULATOR; BOTH RELEASES.

squarely over one of the contacts, thereby preventing insufficient contact between the stationary plates and the brush. After the armature resistance has been all cut out by the arm, the next step inserts the first section of resistance in the field circuit. When the ratchet is released by the magnet, the arm is thrown to the "off" position by a spring in the usual fashion. The illustration shows the box equipped with an overload release magnet of the short-circuiting type—arranged to short-circuit the other magnet—but the controller is also built without this. It is also built without the field regulating feature, speed regulation being accomplished by varying the resistance in the armature circuit, and all

FIG. 26.—REVERSING STARTER AND REGULATOR; NO-VOLTAGE RELEASE.

other features being the same as in the type described.

The Cutler-Hammer Company also builds an entirely enclosed form of combined starting and speed regulating box,

with and without reversing features and with different automatic combinations. Fig. 26 illustrates the "Carpenter type" compound reversing controller with fifteen forward and three reverse speed and no-voltage release, for printing presses, machine tools, etc.; Fig. 27 is the diagram of connections. The lever cuts in and out resistance in the armature circuit and also inserts more or less resistance in the shunt field circuit in the manner clearly shown by the diagram. It has two arms, solidly connected, one of which controls the armature resistance and one reversing contact and the other controls the field resistance and the other reversing contact. A curved rack on the face-plate co-operates with a roller on the under side of the arm shown in the horizontal position, so as to hold the arm in any running position at which it may be set and prevent the brush being left in a position bridging two of the contact plates and not making adequate contact with either of them. The no-voltage release magnet is provided with a disc-shaped armature mounted on the end of a slider which carries also a copper disc adapted to bridge two stationary contacts and thus complete the armature circuit of the motor. The magnet armature, however, when in its lowest position, is not situated near enough to the magnet poles to enable them to lift it, so that if the supply current should be cut off accidentally while the regulating lever is set at full speed or some intermediate point, and should be restored while the lever is still so set, the magnet will not lift its armature and the motor armature circuit will remain open. Moving the regulating arm to the "off" position causes a pin which it carries to lift the curved lever shown just above the pivot post of the arm; the end of this curved lever is linked to the upper end of the slider, which carries the magnet armature, and when the regulating arm is brought to zero, the magnet armature is lifted near enough to the poles to enable them to lift it all the way when the magnet is energized. The motor may be shut down by swinging the regulating arm to the "off" position, of course; an auxiliary carbon break is provided to take the flash and a magnetic blow-out extinguishes it.

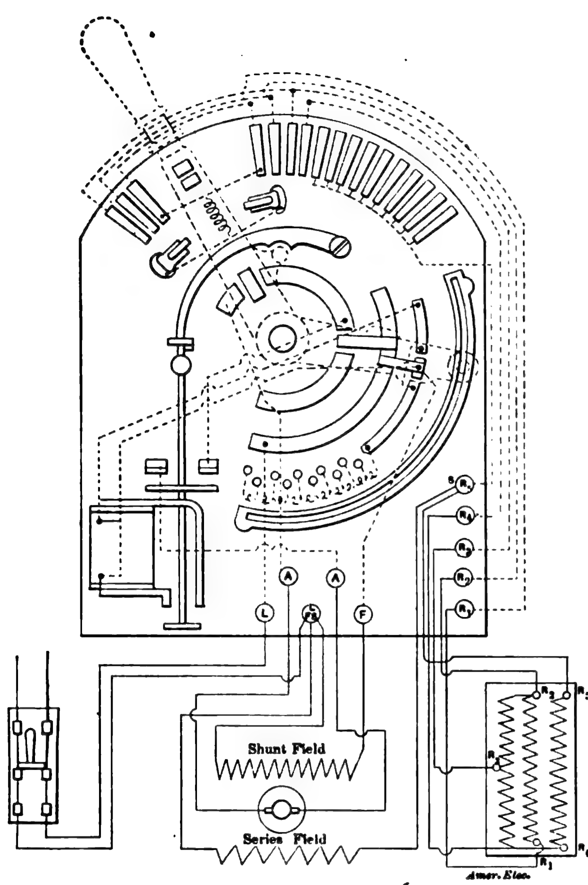

FIG. 27.—DIAGRAM FOR FIG. 26.

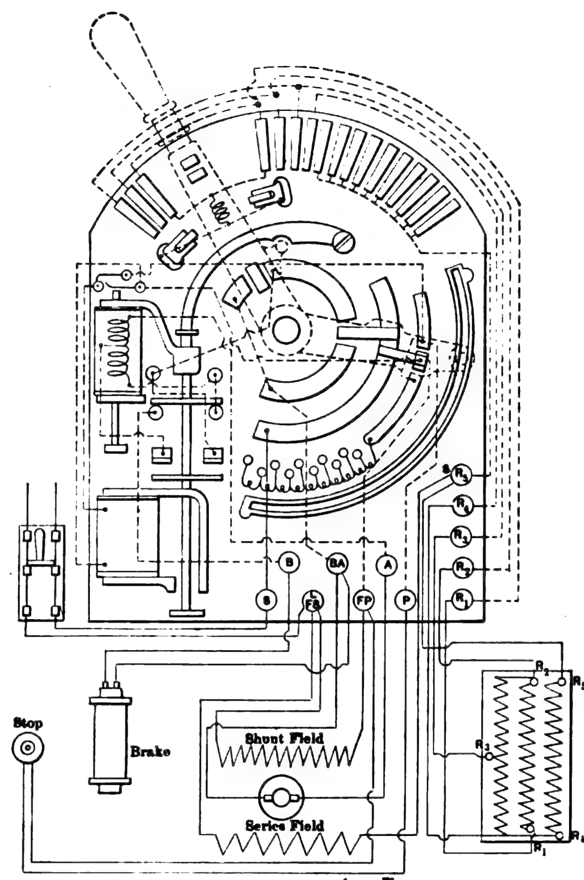

FIG. 29.—DIAGRAM FOR FIG. 28.

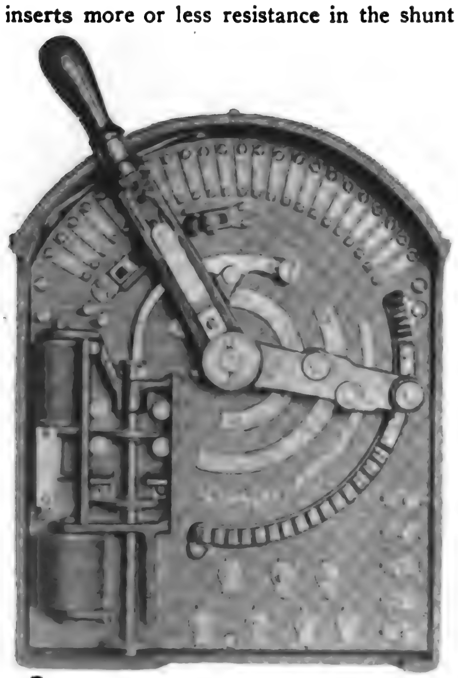

FIG. 28.—REVERSING CONTROLLER WITH BOTH RELEASES.

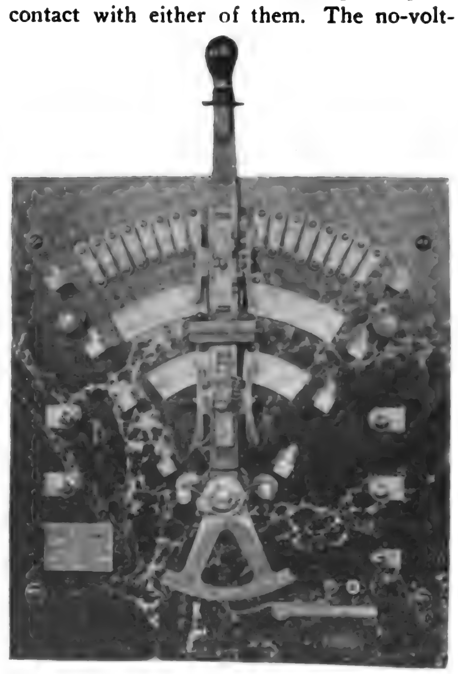

FIG. 30.—CUTLER-HAMMER REVERSING STARTER; NO-VOLTAGE RELEASE.

Fig. 28 shows the same type of controller equipped with overload and push-button release. The overload release consists of a solenoid and plunger arranged to open the circuit of the no-voltage magnet and cause that magnet to drop its armature and open the motor-armature circuit. This break is made on a revolving disc and in a powerful magnetic field which extinguishes the arc instantaneously. This outfit is also provided with a dynamic brake consisting of a resistance which is connected across the armature terminals by an auxiliary pair of contacts located beneath the upper disc on the release-magnet slider so that when the slider drops the brake resistance is connected to the armature. Fig. 29 is a complete diagram of the connections of this controller as applied to a compound-wound motor. The push-button release is merely a circuit-closer of the push-button type connected up to the controller so that closing it energizes the overload solenoid, which is provided with an auxiliary winding for this purpose, and thereby causes the no-voltage magnet to be de-energized and drop its armature.

Full Reversing Hand-Operated Rheostats.

Fig. 30 represents a reversing motor-starter built by the Cutler-Hammer Manu-

facturing Company. Two sets of contact plates are employed and these are cross-connected to avoid duplication of resist-

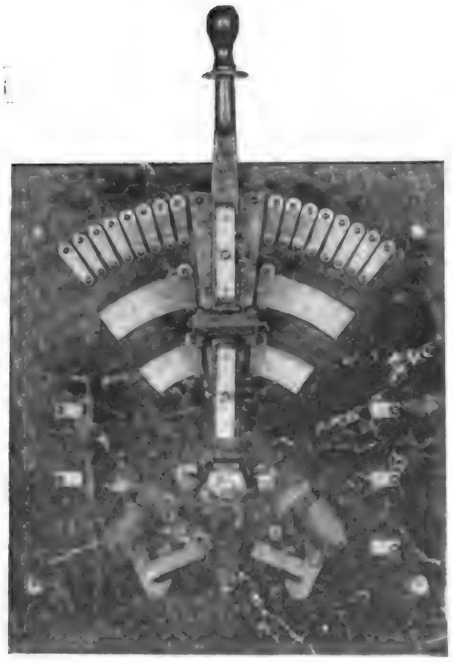

FIG. 31.—CUTLER-HAMMER REVERSING STARTER; NO-VOLTAGE RELEASE.

ance coils; the engraving shows the lever in the "off" position, to which it is returned by one of two springs when not restrained by the no-voltage-release magnet. The magnet holds the lever in either of the full running positions by means of a spring detent attached to the armature and arranged to enter one of two notches in the segment attached to the lever. The rheostat is intended only for starting and bringing the motor to full speed in either

FIG. 32.—CUTLER-HAMMER REVERSING FACE-PLATE CONTROLLER.

direction. The starting lever is divided into two parts which are insulated from each other for the reason that it makes contact with both of the motor brushes in order to reverse the direction of rotation. Each part of the lever carries two laminated copper brushes, one on each edge of it, and when the lever reaches the full

FIG. 34.—WESTINGHOUSE 10-H.P. REVERSING CONTROLLER.

running position in either direction, the two brushes on that side of it short-circuit all of the moving contacts by bridging across stationary contact posts. A similar starting box is shown by Fig. 31, the only important difference being that two restraining magnets are employed and the laminated brushes carried on the edges of the lever in Fig. 30 are not used, the sliding contacts being made of ample area to carry the maximum running current. The

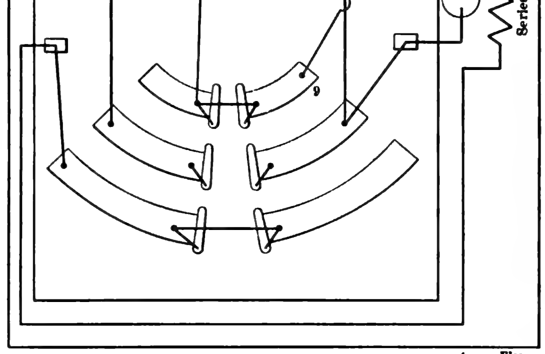

FIG. 33.—DIAGRAM PARTLY APPLYING TO FIG. 32.

restraining magnets hold the arm in the running positions by means of pivoted latches which are automatically set by the short end of the lever as it approaches the "full-on" position. The magnets are connected in series with each other and with the shunt field winding of the motor, directly across the line, so that the field circuit is opened when the lever is drawn to the "off" position, but the magnets have

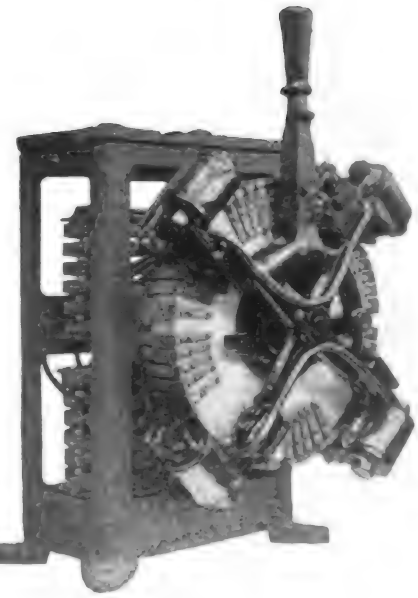

FIG. 35.—WESTINGHOUSE 30-H.P. REVERSING CONTROLLER.

such a powerful "leverage" over the arm that they do not release it until the field magnetism is practically discharged, so that there is no inductive "kick" at the breaking of the connection.

The Cutler-Hammer reversible starter and regulator for crane motors, hoists, etc., is shown by Fig. 32, and Fig. 33 is the diagram of connections for a controller of the same type, but with a single row of contacts. In view of the descriptions thus far

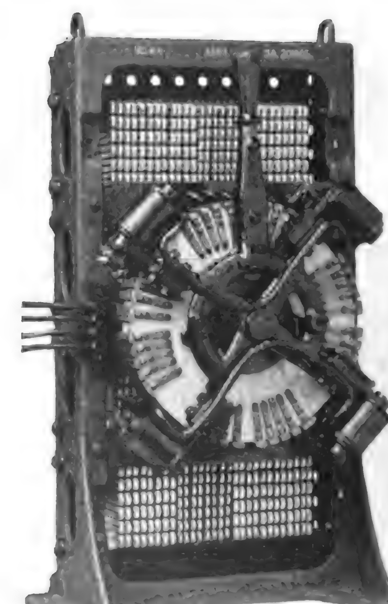

FIG. 36.—WESTINGHOUSE 75-H.P. REVERSING CONTROLLER.

given, these two engravings require no explanation. This rheostat has the unusual feature of a special slow-speed range giving as low as 10 per cent. of the normal full-load speed; the contacts for this slow-

speed range are the three immediately next to the central dead plate on each side, the remaining contacts giving the customary speed ranges up to maximum. Blow-out magnets are provided when necessary for disrupting the arc when the lever is thrown to the "off" position.

Fig. 34 illustrates the reversing and regulating controller of the rheostat type built by the Westinghouse Electric & Manufacturing Company for motors up to 10 horse-power; Fig. 35 shows the form used for motors of 10 to 30 horse-power, and Fig. 36 represents the same class of controller for motors of 40 to 75 horse-power. These controllers are unique in that no separate contacts are employed for reversing the direction of rotation, the arrangement of the brushes and contacts for starting and regulating being such that reversal is accomplished by shifting the spider around to the adjacent row of contacts. For example, lettering the rows of contacts and numbering the four sets of sliding brushes, if brushes *1*, *2*, *3* and *4* have been working on contacts *A*, *B*, *C* and *D* respectively, the motor will be operated in the reverse direction by working brush *1* on contacts *B*, *2* on *C*, *3* on *D* and *4* on *A*. Each brush or set of brushes has its individual blow-out magnet, and the circuit is broken at all four sets of brushes when the lever is thrown to the "off" position. As the illustrations show, the smallest size of rheostat is of the face-plate type, while the others are of an unusual construction, the stationary contacts being mounted around the periphery of a soapstone disc instead of on the face of it.

Resistance Conductors.

In the smaller capacities of motor-starting and speed-regulating rheostats the Cutler-Hammer Company uses helical coils of resistance wire wound on asbestos tubes, as indicated in Fig. 38. The joints are all soldered and so located that they are kept cool even when the resistance coil is very hot. The ends of the asbestos tubes are made moisture proof, and the iron frame in which they are mounted is heavily enameled; it is claimed that the insulation resistance between the conductors and the frame is over a megohm. For larger sizes,

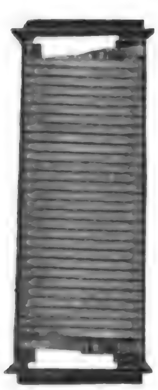

FIG. 37.

FIG. 38.

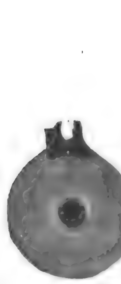

FIG. 39.

the conductor is a thin ribbon wound on an insulated iron frame, as shown by Fig. 37; the material and the insulating precautions are the same as in the smaller type. The next higher capacity is a thicker ribbon wound into a disc, as shown by Fig. 39, with an asbestos strip between the successive convolutions. Grids are also used in the very heavy capacity rheostats.

The insulation of the resistance conductor in the controllers illustrated by Figs. 26

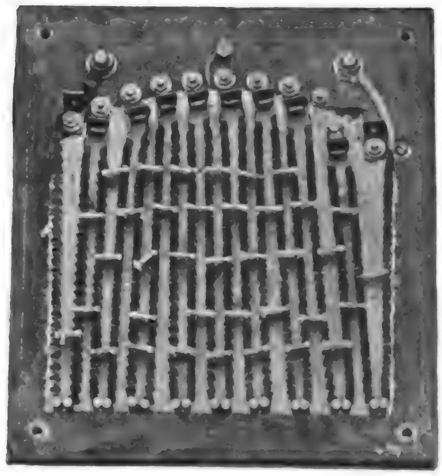

FIG. 40.—WARD-LEONARD RESISTANCE.

to 29 is accomplished in a highly novel manner. A pane of glass, the full size of the resistance case, is laid in the case, and on this are laid strips of glass on which are wound the conductor; on top of these is laid another pane of glass the full interior size of the case. The whole is then heated in an oven to a temperature just sufficient to soften the glass thoroughly, and it is then removed and the mass compressed while the glass is in the softened state; the result is a non-absorptive insulating structure in which the resistance conductor is thoroughly embedded.

The resistance conductor used by the Ward Leonard Company is a special alloy made up in either helical coils of wire or corrugated strips

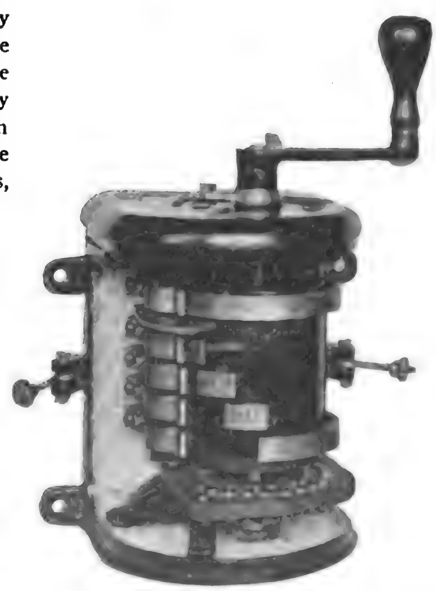

FIG. 41.—CUTLER-HAMMER DRUM CONTROLLER.

of thin ribbon, according to the current to be carried. The conductor is attached to the back of the slate face-plate, as indicated in Fig. 40, several sheets of asbestos being interposed between the conductors and the slate to prevent heating the latter. A hollow iron casing, closed on all sides except the one next to the slate, is then fastened to the slate, a tight joint between the two being made with putty; pure sand is then poured into the casing through a small hole in the wall which is afterwards closed with a plug. The sand completely fills all spaces between the casing and the slate not occupied by the conductor and its fastenings. The claims made for this sand filling are as follows: (1) It has a low temperature coefficient, or more properly, a high specific heat capacity, so that it will absorb and transmit to the iron casing a great deal of heat without an objectionable rise in temperature; (2) it is highly insulating and fire-proof; (3) it does not absorb moisture; (4) it flows freely and makes perfect contact with the surface of the metal ribbon even if the ribbon moves slightly, due to expansion and contraction, or due to vibration; (5) it is a good conductor of heat, hence the heat developed in the ribbon is rapidly and evenly taken up by the mass of sand; (6) it can be readily removed, so that the cast-iron box can be taken off for the purpose of inspection or repair of the resistance, and the same sand can be readily put back again in the box afterward; (7) it fills the entire space and holds the ribbon so that it is not subjected to any mechanical strain; (8) in case the resistance be fused by excessive current, the arc is instantly and quickly extinguished, just as in the case of an enclosed fuse.

Drum-Type Controllers.

For machine-tool motors, the drum type of controller has come more into favor because of its rugged structure, compactness

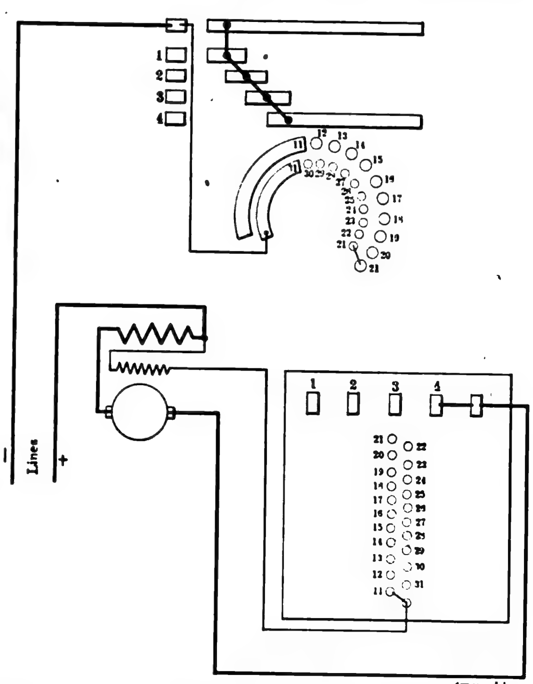

FIG. 42.—DIAGRAM FOR FIG. 41.

and complete enclosure. Fig. 41 represents the Cutler-Hammer drum controller for this class of service, designed for motors to be regulated by field vibration. The starting resistance is cut out of circuit by means of

spring fingers and cross-connecting curved contact plates on the drum, while the field resistance is inserted, little by little by means of a finger attached to the drum immediately below the drum and arranged to travel over a double row of stationary contacts. The general lay-out is clearly indicated in the engraving, and Fig. 42 shows the connections plainly. The resistance coils are

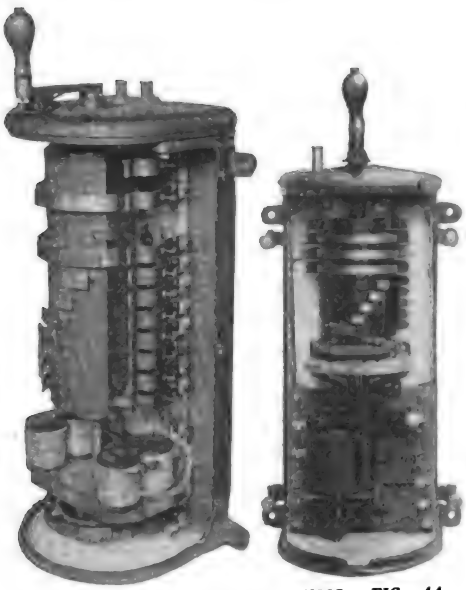

FIG. 43.—CUTLER-HAMMER DRUMS.—FIG. 44.

mounted in a separate frame and connected to the two divisions of the controller as indicated by the numbers on the terminal posts in Fig. 42. Magnetic blow-outs are provided wherever necessary. The controller here shown is non-reversing, but the same type is made in the reversing form, in which the handle is swung in one direction for forward rotation and the other direction for reversing; the lever is prevented from going past the zero point, when thrown back to it, by means of a latch which may be released by the push-button in the center of the controller handle when it is desired to reverse.

Fig. 43 illustrates the Cutler-Hammer

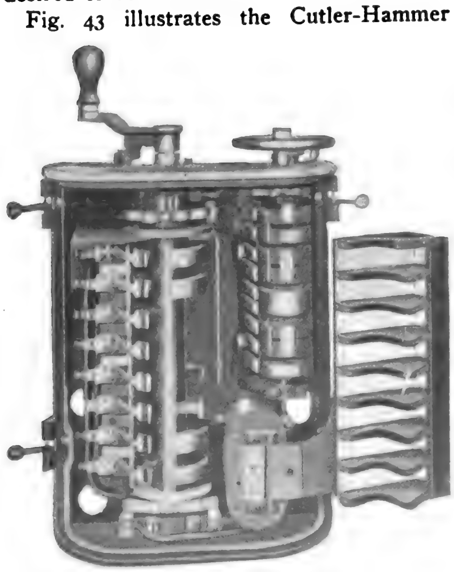

FIG. 45.—GENERAL ELECTRIC RHEOSTATIC CONTROLLER.

drum controller for cranes or other classes of service where speed regulation by variable resistance in the armature circuit is employed. This is a reversing apparatus, and the resistance coils are, of course, contained in a separate frame and connected to the controller by the usual multiple-conductor cable. The main circuit is initially closed and finally broken by contacts in the bottom compartment of the case, and blow-out magnets are mounted directly above this compartment; the contacts on the main part of the drum are for speed regulation only.

When no-voltage and overload release are

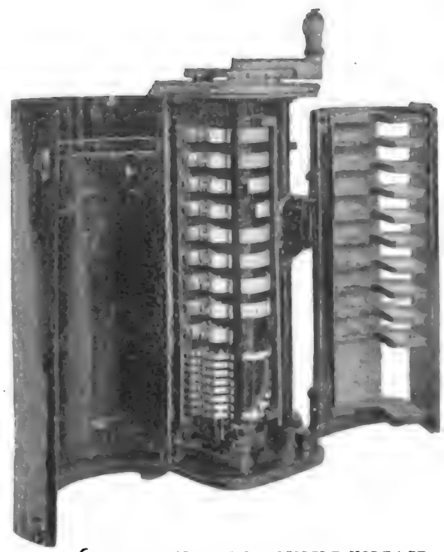

FIG. 46.—WESTINGHOUSE SINGLE-VOLTAGE CONTROLLER.

desired, the Cutler-Hammer drum-type controllers are fitted up as shown by Fig. 44, the magnets being located beneath the drum part of the controller. The no-voltage release device is a solenoid switch, the winding of which is either across the line in series with a small resistance coil or in series with the shunt field winding of the motor, and the switch contacts are in the main motor circuit. The overload release is a small magnet in the motor armature circuit, its armature being arranged to cut out the release magnet when maximum load is exceeded, as previously described in connection with the face-plate types of motor starter.

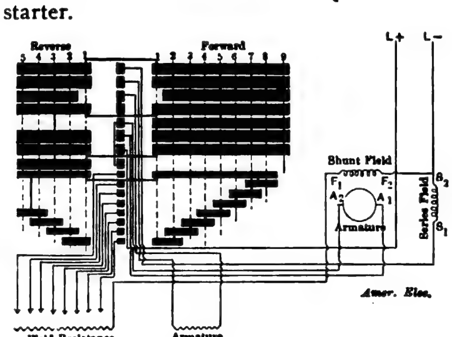

FIG. 47.—SMALL-MOTOR CONNECTIONS.

The General Electric Company makes a very complete line of drum controllers for power and mining-service motors which are of exactly the same general type as the company's well-known street railway apparatus. Fig. 45 illustrates a reversing controller of this class, for rheostatic control; the reversal of the motor is accomplished by means of a separate drum, as in the usual street-car controller, and a powerful blow-out magnet is provided to disrupt the arc when the controller is thrown to the "off" position under a load. The "K type" drum controller is also built for mining motors, cranes and similar heavy duty, where more than one motor is employed and the machines are series-wound; this being a series-parallel controller exclusively.

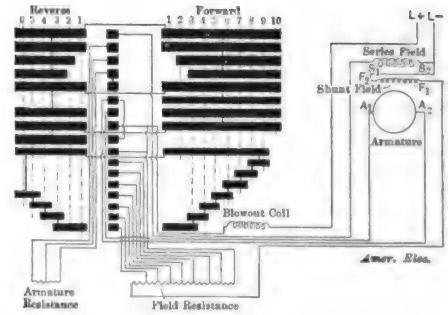

FIG. 48.—LARGE-MOTOR CONNECTIONS.

The Westinghouse Electric & Manufacturing Company builds drum-type controllers for both single voltage and double voltage, the latter being used in connection

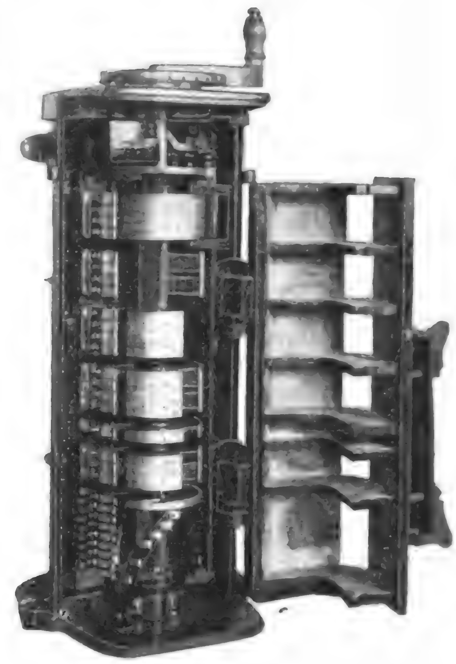

FIG. 49.—WESTINGHOUSE DOUBLE-VOLTAGE CONTROLLER.

with the Westinghouse three-wire system or any other giving the same two fundamental voltages. Fig. 46 illustrates the single-voltage controller; in medium and larger capacities, this type has two starting notches and gives eight forward running speeds and four reverse speeds. Speed control is effected entirely by varying resistance in the shunt field circuit, resistance coils being

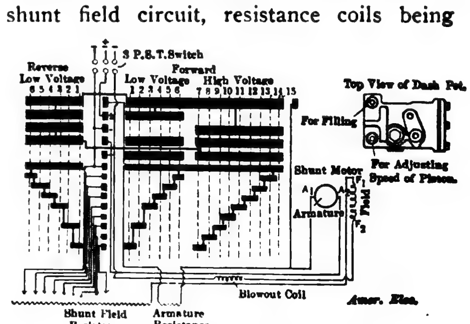

FIG. 50.—DIAGRAM FOR FIG. 49.

used in the armature circuit for starting only. The resistance coils are all mounted in a separate frame and connected to the controller and the motor by cables. Fig. 47 is the diagram of connections for the 10-h.p.

size and Fig. 48 is that for larger sizes, the controller strips being shown "developed." The double-voltage controller is represented

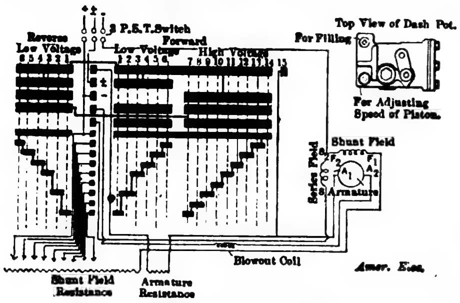

FIG. 51.—DIAGRAM FOR FIG. 49.

by Fig. 49; Fig. 50 is the corresponding diagram of connections for this controller used with a shunt-wound motor, and Fig. 51 the diagram for use with a compound-wound machine. The controller gives fifteen forward speeds and six reverse speeds, six of the forward speeds and all of the reverse speeds being obtained on the lower voltage and the remaining nine forward speeds at the higher voltage. The starting resistance is automatically cut out by a spring-actuated contact which is released by the controller and retarded by a dash-pot. In both the single-voltage and double-voltage controllers the notched disc which locates the controller "points" is so arranged that it is difficult for the operator to sweep the handle past a notch without a pause.

Remote Control Apparatus.

The industrial field in which remote control of direct-current motors is chiefly practised is that of electrically-driven elevators; there are, of course, several special cases such as turret motors on warships, derricks and hoists in peculiar situations, high-speed electric railways such as the Manhattan elevated and subway systems, etc. Space limitations preclude a discussion, even of the briefest kind, of all such special apparatus and systems.

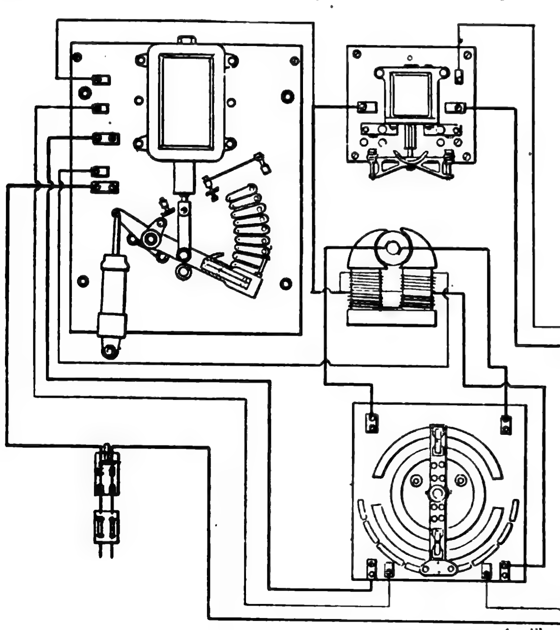

FIG. 52.—ELEVATOR SYSTEM WITH MECHANICAL PRIMARY CONTROL.

In the electric elevator field, the connection between the apparatus manipulated by the attendant and that which directly controls the motor may be either mechanical or electrical; the latter is becoming more and more preferred over the former, which is employed now almost exclusively for freight service and unimportant passenger installations. Even when mechanical primary control is employed, the mechanism which effects the acceleration of the motor from standstill to full speed is purely automatic after it has been

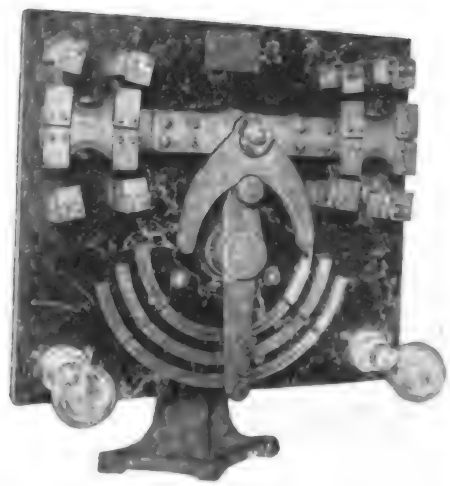

FIG. 53.—MECHANICALLY-OPERATED REVERSING SWITCH.

released by the operator. As a general rule such a system comprises a main reversing switch operated mechanically by means of either a hand-rope or a wheel and small cables from the car, a switch for cutting out the starting resistance and arranged to be put into operation by the closure of the reversing switch in either direction, and either a simple mechanical connection between the brake-band or shoes and the reversing switch or a solenoid put in circuit by the closing of the reversing switch and arranged to release the brake.

Fig. 52 is a diagram of one of the Cutler-Hammer elevator systems with mechanical primary control from the car. It consists of a reversing switch, which is shown in Fig. 53, a main circuit-closing solenoid switch, shown by Fig. 54, and another solenoid switch, Fig. 55, which cuts out the resistance in the armature circuit. Referring to Fig. 53, the horizontal arm makes the connections to the brushes of the motor which determine its direction of rotation and the vertical arm closes the circuit of the main solenoid switch and then that of the accelerating switch. The vertical arm is mounted on a spindle which carries on its other end a sheave to which the cable running to the elevator car is attached. When the operator pulls the switch arm to zero it breaks the exciting circuits of the main-switch solenoid and accelerating solenoid and then throws the reversing-switch arm to the mid position; it also connects to the shunt field terminals the two incandescent lamps on the panel so that the field magnet may discharge without an objectionable "kick." The diagram shows a circular type of reversing switch which is used for small capacities, but the reader will easily understand the substitution of the knife-blade switch shown by Fig. 53. The automatic accelerating switch (Fig. 55) is provided with a small auxiliary contact finger which short-circuits an incandescent lamp connected in series with the solenoid winding; when the lever is drawn up to the position of full speed it lifts this finger and puts the lamp actively in circuit with the winding and prevents overheating. The main solenoid switch is equipped with auxiliary carbon-faced contacts which take the arc when the circuit is opened; it also has powerful blow-out magnets mounted on the back of the panel with their poles projecting through holes on each side of the vertical plane of each pair of carbon contacts.

The highest development in the way of electric elevator controlling apparatus comprises solenoid-actuated switches for making all contacts, a simple two-way switch in the elevator car serving to put the apparatus into or out of operation. Fig. 56 illustrates an outfit of this type built for four sections of starting resistance in the armature circuit and having a special equipment of pressure regulators. The two switches at the bottom of the panel close the main circuit to the motor, the one for operation in one direction and the other for running in the contrary direction. The solenoid windings of these two are connected to the supply cir-

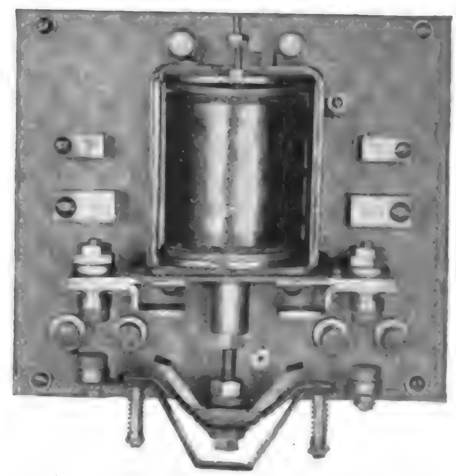

FIG. 54.—CUTLER-HAMMER SOLENOID SWITCH.

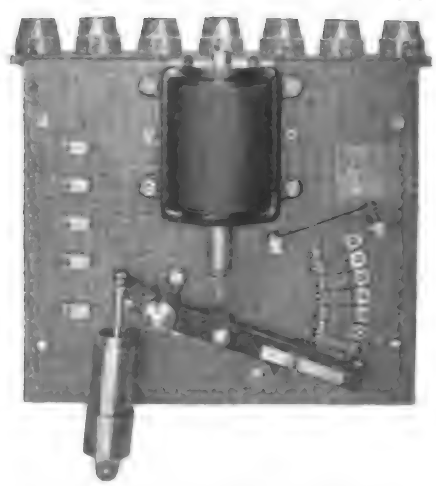

FIG. 55.—CUTLER-HAMMER ACCELERATOR.

cuit by the hand switch in the car. When either of them closes the motor circuit it also closes the circuit of the upper left-hand solenoid, and this draws up its plunger gradually, the motion being retarded by the dash-pot; as the brush on the free end travels over the row of stationary contacts, it closes the circuits of the four small solenoids successively, and these cut out the sections of the starting resistance in the armature circuit. Each of the switches is equipped with carbon contacts which take the flash at the breaking of the circuit. This type of controller is also built for non-reversing motors, in which case one of the main solenoid switches is omitted, of course.

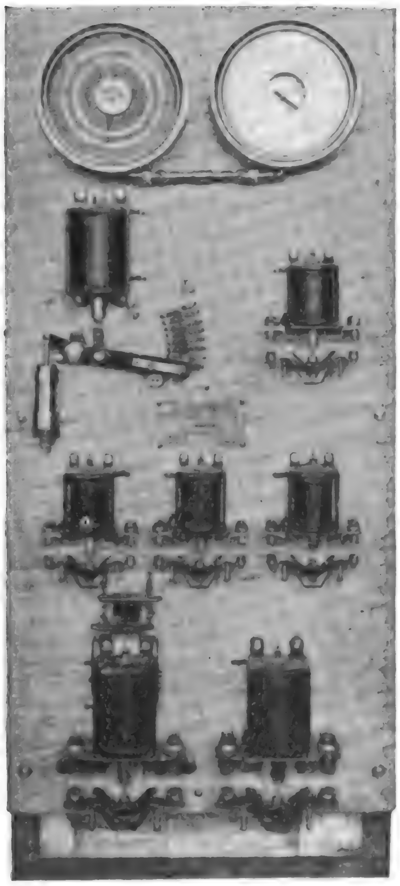

FIG. 56.—CUTLER-HAMMER ELEVATOR CONTROL PANEL.

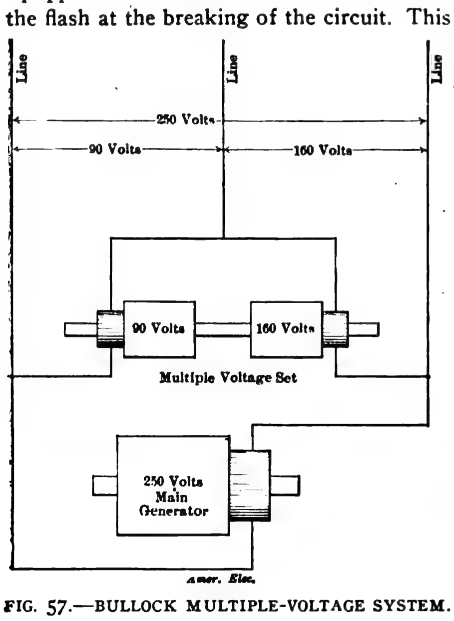

FIG. 57.—BULLOCK MULTIPLE-VOLTAGE SYSTEM.

Special Control Systems.

Besides the apparatus built for controlling motors supplied from simple supply circuits, there have been developed complete systems of speed control of which the fundamental feature is either the variation of the applied e.m.f. at the armature terminals by means other than dead resistance or variable grouping of two armature windings combined with variable field strength. One of the earliest of the multiple-voltage systems to be exploited for industrial purposes was that of the Bullock Electric Manufacturing Company. In this system, a 250-volt generator is employed to give the maximum voltage and supply the energy to the distribution mains and a motor-balancer is used to furnish the lower voltages; this arrangement is indicated diagrammatically by Fig. 57, where the motor-balancer is designated "Multiple voltage set." This set operates on the same principle as the ordinary pair of coupled motors on a three-wire system in which the voltage is the same on both sides of the neutral conductor. As the diagram indicates, the lowest fundamental voltage is 90 volts, and the e.m.f. on the other side of the middle wire is 160 volts. The controller, of which Fig. 58 is a view with the cover removed and Fig. 59 a diagram of connections, starts the motor on the 90-volt wires and varies the resistance in the field circuit to give three speeds at this voltage; it then shifts the armature to the 160-volt wires and repeats the variation of field excitation; the next "notch" puts the armature on the outer wires, at 250 volts, and there are six forward and three reverse speeds at this voltage, making twelve forward and nine reverse speeds in all. The armature resistance is inserted each time the motor is shifted to a pair of wires of higher voltage, and is immediately cut out by a solenoid which is put in and out of circuit by the controller drum. The motor field winding is excited from the outer wires in all positions of the controller. The reverse speeds, as the diagram indicates, are obtained by swinging the controller handle in the opposite direction from that which gives forward rotation. Fig. 60 shows the motor-balancer, which requires no further description.

The Bullock Company also builds a four-wire, six-voltage system which gives twenty-six forward and six reverse speeds, a three-motor balancer being employed to sub-divide the main voltage. Fig. 61 is a diagram of the voltage distribution; the voltages are 60, 80, 110, 140 (between wires *A* and *C*), 190 (between wires *B* and *D*) and 250. These, of course, give six speeds, and the

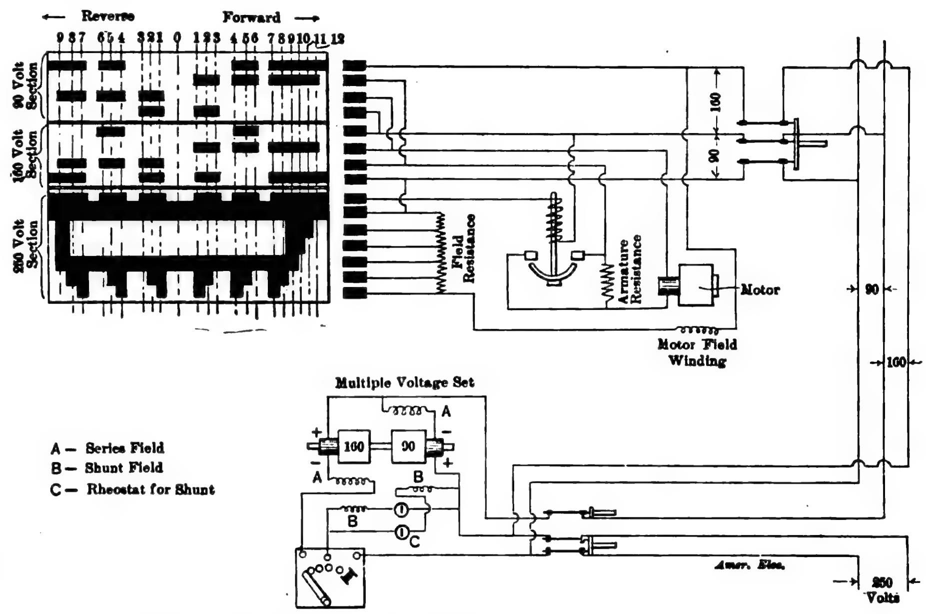

FIG. 59.—DIAGRAM OF CIRCUITS, BULLOCK MULTIPLE-VOLTAGE SYSTEM.

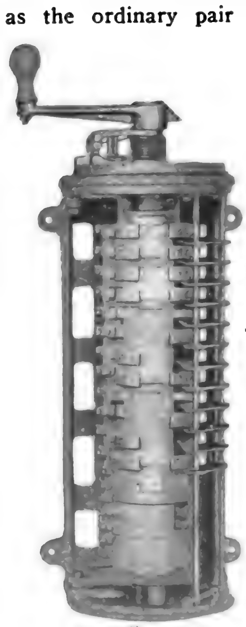

FIG. 58.

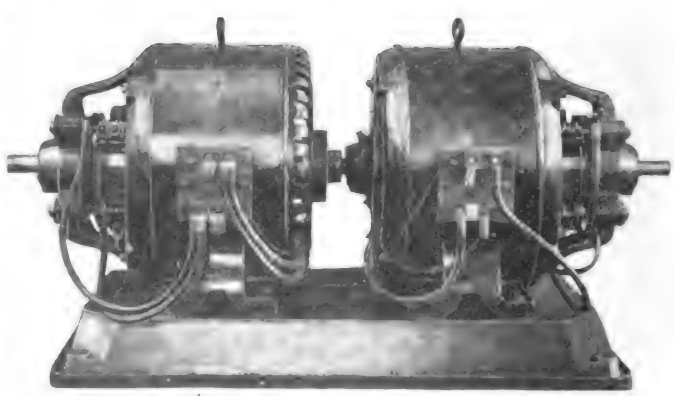

FIG. 60.

CONTROLLER AND BALANCER FOR BULLOCK MULTIPLE-VOLTAGE SYSTEM.

other twenty are obtained by varying resistance in the shunt field circuit of the motor. The total speed range is usually about $7\frac{1}{2}$ to 1.

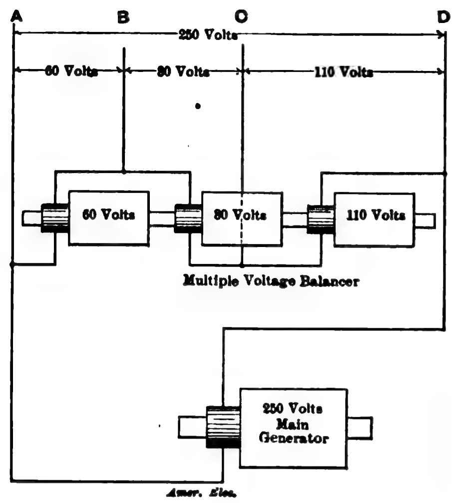

FIG. 61.—BULLOCK FOUR-WIRE MULTIVOLTAGE SYSTEM.

The Crocker-Wheeler Company also builds a multivoltage system in which the fundamental voltages are obtained by means of a motor-balancer. These are different, however, in value from those of the system just described, being 40, 80 and 120;

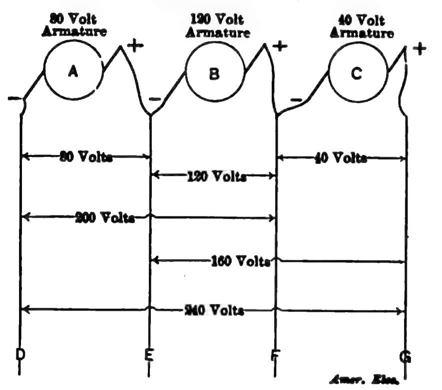

FIG. 62.—CROCKER-WHEELER FOUR-WIRE MULTIVOLTAGE SYSTEM.

combining the highest of these voltages with each of the lower ones gives 160 and 200 volts, and the e.m.f. between the outside wires of the system is 240 volts; see Fig. 62. The controller is of the usual

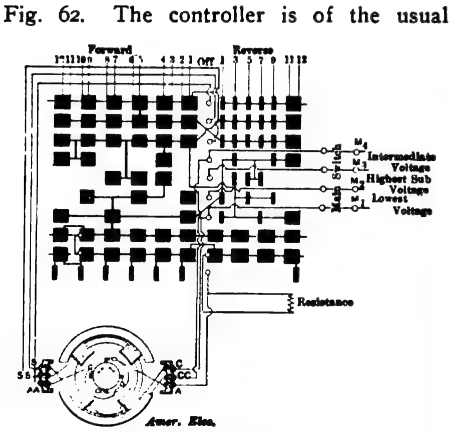

FIG. 63.—CROCKER-WHEELER CONTROLLER CONNECTIONS.

drum type, and gives twelve forward and seven reverse speeds. The intermediate speeds between the six obtained by the different voltages are obtained by a resistance in the armature circuit, field regulation not being used. All of the controller notches are running points; the first one puts the armature on the lowest voltage with the armature resistance in circuit; the second one cuts out the resistance; the third one shifts the armature to the second voltage with the resistance in circuit; the fourth one cuts out the resistance, and so on. The shift from one voltage to the other is made with a quick snap motion of the drum by means of a spring connection, so that the flashing at the contacts when the circuit is momentarily opened is reduced to a harmless value. Fig. 63 is a diagram of the controller connections and contacts; it will be noted that the reverse speeds, except the highest one, are the same as those forward speeds at which the armature resistance is in circuit.

When it is requisite that a finer speed gradation be obtained, the Crocker-Wheeler system is built with field-resistance regulation for the intermediate speeds, the armature resistance being used merely as a "buffer" at starting and when the armature is shifted from one voltage to the next. With this arrangement, any reasonable number of speeds may be had. The total range is usually 10 to 1.

The C. & C. Electric Company manufactures a multiple-speed motor system in which the motor has two armature windings and commutators, the two being connected in series or parallel by the controller. The system was designed originally with especial regard to the conditions to be met in the operation of large printing presses, but it has been found so well adapted to other purposes that it is in extensive use in dry-docks, manufacturing establishments, etc. The controller primary consists of a rheostat of the face-plate type, the arm of which is mounted on a spindle which also carries a spur gear that meshes with a segmental rack; the operating handle is attached to this rack, and the gear connection between it and the traveling brush of the rheostat permits a wide range of travel by the brush and a relatively short travel of the operating handle. Fig. 64 shows the arrangement described, the operating handle being shown separate from the

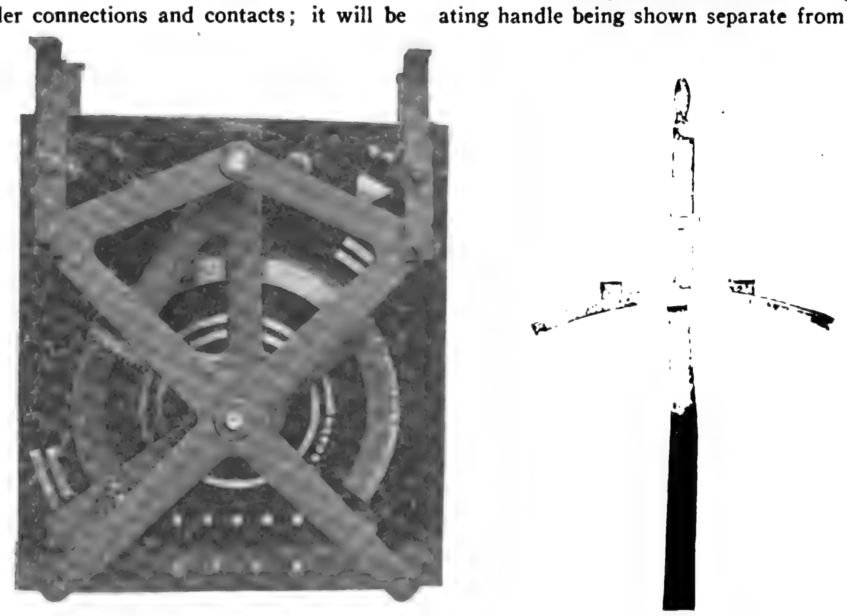

FIG. 64.—C. & C. SERIES-PARALLEL RHEOSTAT AND OPERATING LEVER.

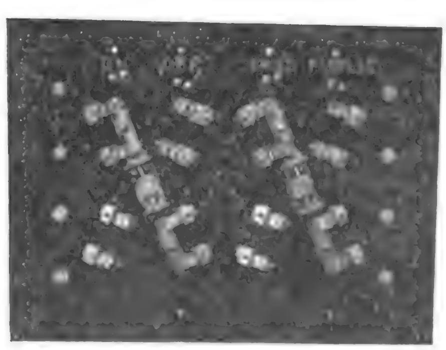
rheostat; the rheostat here illustrated was designed for mounting on the ceiling of a room or pit beneath the pressroom, the operating lever extending through the pressroom floor to the segmental rack. The revolving arm on the rheostat cuts in and out resistance in the shunt armature field circuits of the motor and also connects and disconnects the windings of two solenoids which actuate switches for connecting the motor to the supply circuit and for connecting the two commutators in series or parallel.

Fig. 65 illustrates the panel carrying the two solenoid switches just mentioned; the left-hand switch connects the motor to the supply circuit and disconnects it, and the



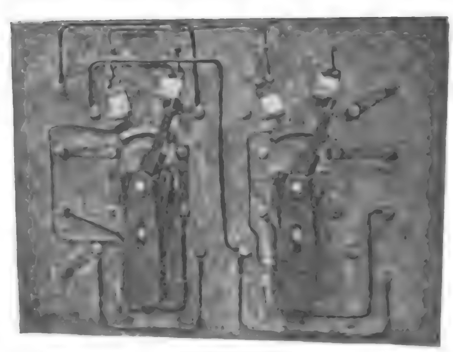


FIG. 65.—C. & C. MAIN AND SERIES-PARALLEL SWITCHES.—FIG. 66.

right-hand switch puts the armature windings in series or parallel. Fig. 66 is a view of the rear of this panel; each switch is actuated by a single solenoid, the linkage between the plunger and the switch arm

being such that the switch is thrown to the opposite position that it occupies when the solenoid is excited, no matter which position this is; moreover, it cannot remain in any position except one of the two extremes of its travel.

Referring again to Fig. 64, it will be noticed that there are two pairs of short arc-shaped strip contacts on the panel just outside the circle of rheostat contacts; one of these when bridged by the traveling brush on the rheostat arm closes the circuit of the main-switch solenoid and the other closes that of the series-paralleling solenoid. The two circular contact strips near the center of the panel are the shunt field connections, and the small buttons near the right-hand end of the outer strip are for the purpose of inserting resistance sections in the field circuit. The operation is as follows: When the controller lever is moved from the "off" position to the first notch on the quadrant, the rotating arm connects the main-switch solenoid to the circuit, and the switch is closed; it also puts the brush on the first armature-resistance contact and the motor is started at the lowest speed, which is a mere "crawl" for the purpose of "inching" the press. Further movement of the controller lever cuts out resistance in the armature circuit as usual. The series-parallel switch is at this time closed so as to put the armature winding in series.

When the rheostat arm has progressed far enough to cut out all of the armature resistance, the next step carries it to the point where it bridges the two strips which are connected to the series-parallel solenoid and the supply circuit, and simultaneously inserts enough resistance in the armature circuit to make the speed the same with the windings in parallel that it was when they were in series without any resistance. Further movement of the controller cuts out the armature resistance gradually, and when it is all out, the arm reaches the buttons in the field circuit and inserts resistance five sections of one at a time. When the controller lever is swung backward the reverse effects are produced, of course; as it passes the series-parallel solenoid contacts, it energizes that solenoid which throws the switch back to the series position; when it nears the original starting point, where all the armature resistance is in circuit, it closes the exciting circuit of the main-switch solenoid, which opens the switch, of course. The closing and opening of this switch are both accomplished with the armature circuit closed at the rheostat brush, so that there can be no arcing at the initial rheostat contact. The system also includes push-button stops, which may be located at any points and the closure of any one of which will excite the two switch solenoids and thereby cause the motor to be disconnected instantaneously and the windings to be put in series, ready for the next start. The motor then cannot be started up without moving the controller lever back to zero, because the main-switch solenoid cannot be excited until the arm bridges the contacts located at that position. If the motor is shut down by a stop button while the arm is beyond the point where it shifts the armature windings to parallel, moving it back past the series-parallel solenoid contacts on the panel will not throw the switch because the exciting circuit of that solenoid is "dead" when the main switch is open; the series-parallel switch remains, therefore, in the series position to which it was thrown by the closing of the stop button.

Another double-commutator system, extensively used for machine-tool, printing-press and other special classes of service, is that of the Commercial Electric Company, Indianapolis, Ind. In this system the motor has two armature windings and commutators, but the windings are not exactly alike, as in the case just considered. One winding has usually two-thirds the number of turns that the other contains; consequently, four fundamental speeds are obtained. With the two windings in series differentially (the smaller one opposing the larger) the maximum fundamental speed is obtained; with the smaller winding in circuit alone, the speed is about one-half the maximum; with the larger winding in alone, the speed is about one-third of the maximum, and with the two windings in series in the same direction, the speed is about one-fifth of the maximum. Intermediate speeds are obtained by varying a resistance in the shunt field circuit. The two armature windings have the same current-carrying capacity, so that the motor exerts full horse-power at all speeds. The controller is of the dial type, completely enclosed in a rectangular case which also contains the resistance coils and a starting switch operated by means of a separate handle on one side of the case; the speed-regulating handle is at the top of the case like that of the ordinary street railway controller. The regulating switch consists of an arm swinging about a pivot and carrying at both ends contact brushes which travel over a circular row of contact plates. On the front panel of the case are mounted the fuse-holders and an automatic double-pole circuit-breaker.

In conclusion, the writer desires to point out that the selection of the apparatus and systems herein described was made with a view to covering as nearly as possible the principal fundamental types, space limitations making it utterly impossible to describe every modification and alternative type. The lack of reference to any generally typical apparatus or system that has not been described is not due to any intention to discriminate, but solely to failure on the part of the maker to furnish the requisite material. The writer also extends thanks to those manufacturers whose kindly co-operation has enabled him to present the brief descriptions contained in this article.

Abstracts from Foreign Contemporaries

Cement-Covered Wood Poles.—R. W. Pope calls our attention to the fact that the idea of a cement-covered wooden pole is not as recent as the note on that subject published in this department last month would indicate. From references furnished by T. D. Lockwood it appears that as far back as 1835, Brunel suggested an easy way of defending piles, which was to give them a coat of tar, and then powder them with brick-dust which would render the wood sufficiently hard to receive a coat or two of cement. In "A Treatise on Dry Rot in Timber," by Britton, published in 1875, mention is made of wooden casings formed around poles, the intervening space being then rammed full of cement. Poles of cement were used in 1868 on the telegraph line from Aspinwall to Panama in South America.

A New Insulating Material.—E. Holthaus, in writing to the *Elektrotechnische Zeitschrift*, describes a new insulating material, named galalith, made by the Harburger Gummi-Kamm Co. It is prepared from skim milk, by a process on the whole similar to that employed in the production of ebonite. The result is a material having a structure which also resembles that of ebonite or horn. Water is first removed from the skim milk, the resulting product being hardened and then treated with certain acids, the material thus obtained being plastic. It is next pressed by hydraulic power into definite shapes, and is finally treated in a drying stove. Galalith is said to be from about 28 to 30 per cent. more elastic than ebonite, and is easily machined. Its density is about 1.4. With regard to insulation resistance and disruptive strength, it is somewhat inferior to ebonite, but it is stated to have a disruptive strength about equal to that of porcelain. This new material is not attacked by fatty substances, oils, benzine or alkalies, and is odorless. It appears that 60 litres (about 13 gallons) of skim milk are required for every kilogramme (2.2 lbs.) of galalith produced.

The Effect of Oil on Boiler Furnaces.—In a paper on "Boiler Furnaces and the Effect of Oil on their Ultimate Strength," recently read by Mr. D. B. Morison, before the Northeast Coast Institution of Engineers and Shipbuilders, the author said that if the surface of a furnace in a boiler for, say, 200-lb. pressure, were clean, the temperature of the metal would never reach the point at which its original tensile strength would be appreciably reduced, even under very high rates of evaporation. If, however, the surface were simply rubbed over with a very thin coating of mineral oil, the temperature would at once rise to 650 deg., even with a moderate rate of evaporation. An appreciation of this fact would explain many a so-called mysterious collapse of furnaces, in apparently clean boilers. If a mere coating of oil of inappreciable thickness would raise the temperature of the metal beyond the safe limit, it

followed that an extremely thin scale or deposit, containing a high percentage of oil, must inevitable result in dangerous overheating. A disastrous accident of this nature came under his notice some time ago, in which the furnaces collapsed. The boilers were apparently clean, with no appreciable scale on any part, and the principal cause of the accident was the use of a very inferior oil for swabbing the rods and lubricating the auxiliary engines. The oil becoming emulsified with the feed water, and being therefore unfilterable, passed directly into the boilers. Practically no oil was ever present in the harmless-looking deposit found on the crown of a collapsed furnace, simply because the temperature of the plate had been so high as to drive off the oil by distillation, but if deposit were scraped from other parts of the boiler, it would, on analysis, never fail to afford a solution of such furnace accidents as were sometimes termed "mysterious," by those who did not realize the dangerous effects of a very slight coating of deposit rich in oil.

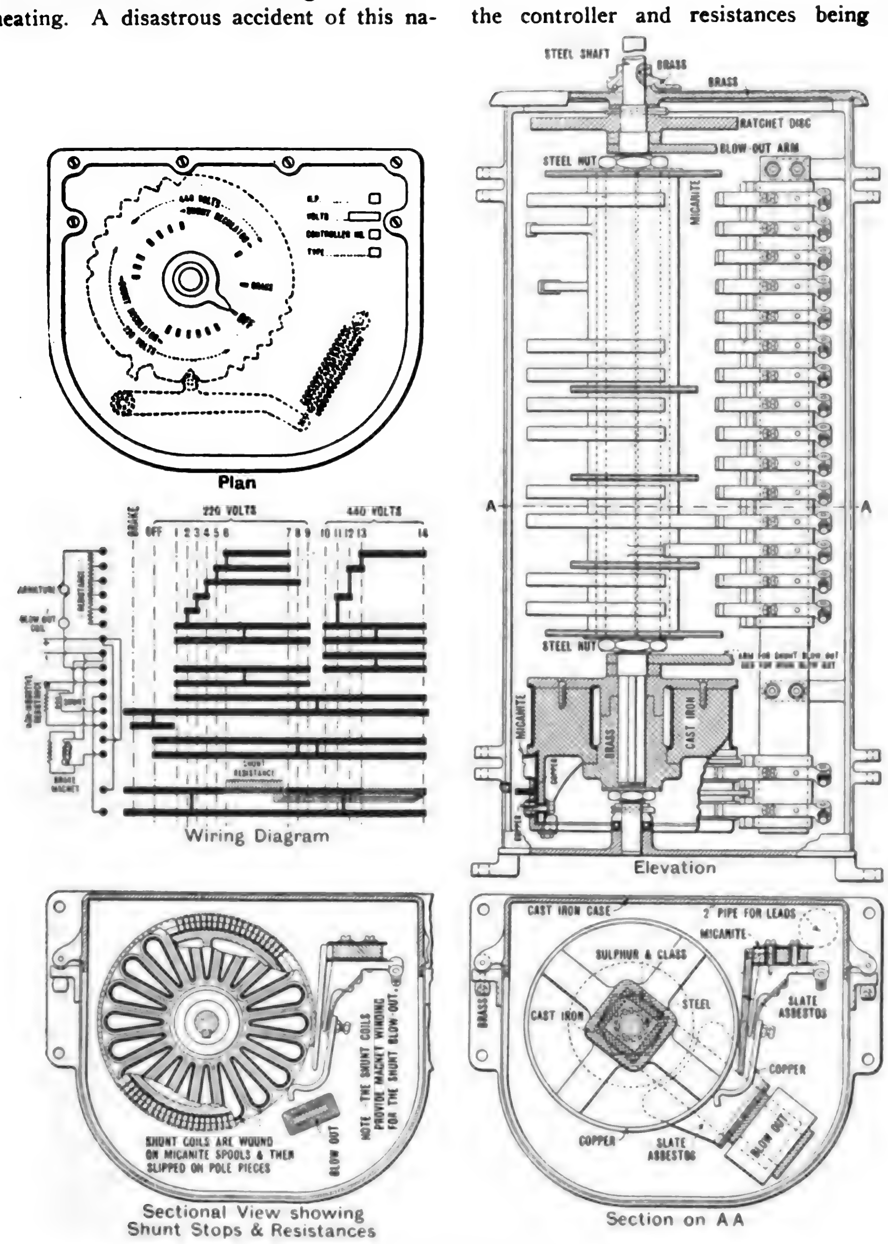

FIG. 1.—DOUBLE-VOLTAGE MOTOR CONTROLLER.

Double-Voltage Motor Controllers.—The London *Electrician* describes the double-voltage controllers used in connection with the variable-speed motors installed in the shipbuilding works of Harland & Wolff. The two voltages are 220 and 440, and a wide range of speed regulation is allowed, the controller and resistances being designed so that it can be left on any stop without injurious heating. For all sizes up to and including 15 horse-power the following cycle of operations will serve to illustrate the different speeds at which the motors may be run. The shunt is excited at 440 volts, and is switched on the mains just before the armature circuit is completed. Commencing from the "off" position and moving the controlling lever in a clockwise direction, the following obtains:

Off Position.
(1) Brake magnet excited—Brake lifted.
(2) Shunt resistance connected across kicking coil.

1st Starting Position.
(1) Ditto as regards brake magnet.
(2) Shunt excited across 440 volts and no resistance in series with its winding, giving maximum strength of field.
(3) Armature in series with all starting resistance across 220 volts.

2nd to 5th Starting Positions.
(1) and (2) Ditto.
(3) Armature starting resistance gradually cut out.

6th Running Position.
(1) and (2) Ditto.
(3) Starting resistance all cut out and armature direct on 220 volts, giving lowest normal speed.

Then follow 20 shunt regulating positions, resistance being inserted in series with the field winding. To obtain a further increase in speed the motor armature must be brought across the 440-volt mains. In order that the motor shall not have time to slow down, the next move must be made quickly. First, the shunt resistance is short-circuited to give a strong field, and then the armature resistance is inserted in two sections to reduce the arc formed on breaking before changing over to the first step on the 440-volt circuit. The next series of operations repeats that detailed on the 220-volt system with the exception that the armature resistance is cut out in three sections, giving four speeds instead of six, as on the lower voltage. By this arrangement no less than 40 different speeds can be obtained by shunt regulation. The controllers are fitted with contacts to which a magnetic brake can be connected, the shunt coil of the latter being de-energized when the controlling lever is moved in a counter-clockwise direction to a stop beyond the "off" position, thus allowing the gravity brake to act. The field winding is immediately short-circuited through a non-inductive resistance upon being cut off from the mains. In general appearance the controller is similar to that used on street cars. The shunt rheostat is self-contained in the controller case; but the armature resistance is separate, this being contained in enclosed ventilated iron boxes. The resistance consists of iron grids. The shunt rheostat is on a drum fitted in the base of the controller. The copper contacts are built up in the form of a commutator, while the resistance is wound on micanite bobbins, the wire used being double-cotton covered. The contact fingers are of hard-drawn copper, the links between these and the brass carriers being of laminated phosphor bronze. These carriers are carried upon and clamped to a mild steel bar rectangular in section, and are insulated from it by a micanite tube which fits over the entire length of the bar. Both armature and shunt contacts are protected by magnetic blow-out coils swiveled upon the main shaft; the shaft becomes one pole of the blow-out magnet, the magnetic path being directly across the point of contact of the fingers.

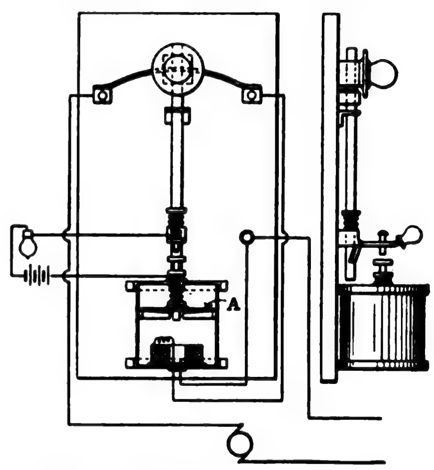

FIG. 2.—THERMAL CUT-OUT.—FIG. 3.

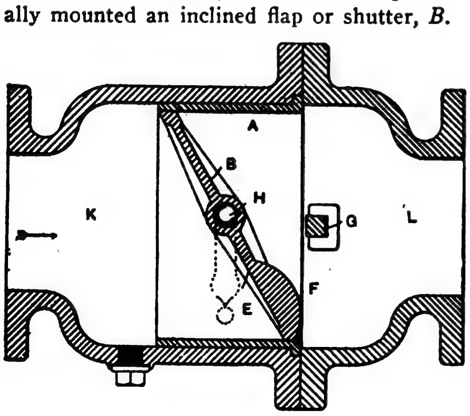
Time Element Thermal Cut-Out.—The thermal cut-out shown diagrammatically by Fig. 2 herewith, is described in a recent issue of the London *Electrician*. It is designed to act only after an over-load has

lasted a predetermined time. Its principal parts are a closed corrugated receptacle, *A*, of sheet metal, in the form of a disc, containing a quantity of ether and a small resistance coil placed underneath the ether receptacle, both being enclosed in a brass box as indicated in Fig. 3. The whole or part of the current in the circuit to be protected passes through the resistance coil, which begins at once to heat up, thus raising the temperature of the metal disc above it, and the coil may be so proportioned that its rise and fall in temperature with fluctuating current will be commensurate with the temperature variations in the electric apparatus it protects. For instance, when starting up a motor, it will take a given current a longer time to raise the temperature of the motor to a certain value than when the motor has already been warmed up. Similarly, a longer time will elapse before the air above the resistance coil assumes a given temperature after having completely cooled down than after having been heated up by previous service. As a rule, the resistance coil is so designed that about 8½ watts are dissipated per second during ordinary service at full load. When the overload comes on, the increasing temperature of the coil is communicated to the hollow metal disc and to the ether contained in it. The disc consequently bulges out and lifts a small piece of metal, which, in rising, first closes a bell circuit or a lamp circuit, and then, if the overload continues, actuates the trip gear of the main switch (see Figs. 2 and 3). By means of the screw adjustments indicated in the illustrations, the time element may be varied within wide limits. It will be noticed that the main switch cannot be closed again, after being tripped, until the resistance coil and ether disc have cooled down sufficiently. The device does not act, of course, instantly on a short-circuit, the shortest time being about some 10 seconds.

A Simple Design of Non-Return Valve.—Figs. 4 and 5 show sectional views of a non-return or isolating valve for steam pipes, which is described in the London *Mechanical Engineer*. The device comprises a chamber, *A*, in which is pivotally mounted an inclined flap or shutter, *B*.



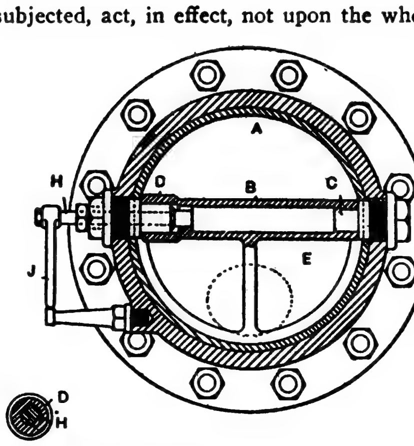


FIG. 4.—SIMPLE NON-RETURN VALVE.—FIG. 5.

The axis of the pivots, *C D*, between which the flap is mounted, is placed slightly out of centre, so that the area of the flap on one side of the axis is somewhat larger than that on the other side of the axis. The larger portion or wing, *E*, is weighted, as shown at *F*, with a view to imparting to the flap, *B*, a tendency to assume the closed position. Across the casing is arranged a stop, *G*, which serves to restrict the movement of the flap. Through one of the pivots, *D*, on which the flap vibrates passes a spindle, *H*, the inner extremity of which is formed as shown, so as to engage with the flap, *B*, in such a manner as to allow thereto a certain degree of free rotative movement. Upon rotating the spindle, *H*, beyond the limits of freedom so afforded it engages with the flap, *B*, and by its means the flap can be opened or closed. The outer extremity of the spindle projects through a stuffing-box, and is fitted with a hand-lever, *J*, whereby the spindle may be rocked. The inner extremity of the spindle may be so connected to the flap that the movements of the latter may be indicated by those of the hand lever, thereby showing whether the flap is in working order. Both the pivots, *C D*, may, if desired, be similarly fitted. The action of the apparatus is as follows: When the steam pressure upon the boiler side, *K*, of the flap is the greater, the flap opens by reason of its unbalanced condition, the area of one of its wings being greater than that of the other. When, however, the boiler pressure falls below that in the steam collecting pipe on the opposite side, *L*, of the flap, *B*, the reverse action ensues, the excess of pressure corresponding with the excess of area on one side of the axis of the flap causing the same to close automatically and to intercept the passage through the casing, thus preventing the return flow of steam. The ordinary pulsations of pressure, to which valves of the kind under consideration are subjected, act, in effect, not upon the whole area of the valve, but only upon the difference of area whereby one wing of the flap exceeds the other. Any violent or excessive vibration of the valve or flap is, under these circumstances, avoided when working under normal conditions. When, however, great difference of pressure suddenly arises—as, for example, in the event of a boiler, or a steampipe between the valve and the boiler bursting—the valve promptly closes.

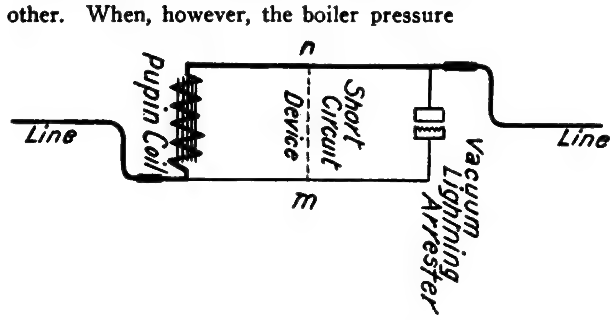

FIG. 6.—METHOD OF INSERTING COILS ON LIN

First Pupin Telephone Line in Austria.—The *Zeitschrift für Elektrotechnik* contains an illustrated article on the first Pupin telephone line in Austria, which connects Vienna with Innsbruck, the distance being 570 km. An ordinary telephone line would have required a bronze wire of a diameter of 4 mm., while with the Pupin system a bronze wire with a diameter of 3 mm. is sufficient, which means considerable saving of the first cost of installation. The transmission line comprises somewhat over 5 km. of underground cable. Pupin coils were inserted on the overhead line at intervals of 4 km. in both wires, each coil having a resistance of 1.2 ohms and a self-induction of 0.08 henry. The coils inserted in the cable line were constructed differently, and were placed at distances of 1,250 meters, having a resistance of 2.5 ohms and a self-induction of 0.2 henry. The way in which the coils were inserted in the lines is shown in Fig. 6. The short-circuiting device between *m* and *n* was used in order to make experiments on the efficiency of the Pupin system. It was thus possible to short-circuit any number of Pupin coils. The system was found to be quite successful, although it was found that half the number of coils was about as effective as the total number of coils.

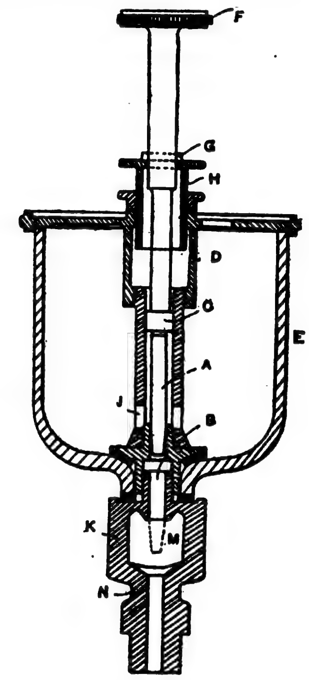

FIG. 7.—DRIP-FEED LUBRICATOR.

Improved Drip-Feed Lubricator.—The *Mechanical Engineer* describes the lubricator shown in section in the accompanying engraving. It is provided with a long conical spindle, *A*, arranged to slide vertically for a considerable distance in the feed passage, *B*, of the lubricator. The spindle, *A*, is in its upper part cylindrical and is a working fit in the passage, *B*, while an enlarged part, *C*, forms a piston which works in a cylindrical extension, *D*.

The upper part of the spindle extends outside the oil-storage vessel, E, and is provided with a handle, F. A pin, G, passes through the spindle, and is arranged to rest on the top of an adjusting screwed collar, H, which forms a neck bush for the sliding spindle. A slot is provided in the upper part of the screwed collar, H, so as to allow the pin, G, to pass downward. Holes, J, are provided in the cylindrical extension, D, and a space, K, is provided in the oil passage. By adjusting the height of the collar, H, the amount of opening to the oil may be readily set to meet the requirements of the bearing or cylinder. For the purpose of cleaning the spindle, A, is turned through a suitable angle, so that the pin, G, registers with the slot in the collar, H, and is thereby permitted to pass downward. The handle, F, is then moved up and down after the manner of a pump. This causes the piston, C, on its upstroke to draw oil in through the holes, J, and squirt it out again on the down stroke, whereby the holes, J, are cleaned of all sticky oil or dirt which may have been deposited there. At the same time the spindle, A, passing through the oil passage, B, to the position shown by dotted lines, effectively clears that passage of dirt or sticky oil by sweeping all such clogging material into the space, K, from which it may be removed by inserting the finger. As usual in such sight-feed lubricators the part, K, of the nipple, N, is provided with an opening, M, through which the drip of the oil may be seen and adjusted to the required amount. It is through this opening that the finger may be inserted for removing dirt. A glass tube may be provided to prevent ingress of dirt through the opening, M, to the oil supply passage, B. When the lubricator is not required the spindle, A, is turned as described above, and allowed to fall to its lowest position, when the piston, C, acts as a seal to shut off the feed.

Some Recent Electrical Patents

Motor-Starting Rheostat.—With a view to avoiding some of the disadvantages of the usual type of motor-starting rheostat with automatic no-load and overload release while retaining the safety features, Mr. Edgar F. Dutton, of Schenectady, N. Y., has devised the arrangement illustrated in partial diagram by Fig. 1 herewith. The main switch is an automatic circuit-breaker, equipped with a double detent, 17, which is pulled into the locking position shown by the solid lines when the shunt magnet, 18, is energized and drawn to the release position indicated by dotted lines when the load reaches the point where the series magnet, 24, overcomes the shunt magnet. The outer end of the detent is much heavier than the inner end, so that with no current on the line it falls to the release position. When in that position, it serves as a stop to prevent the closing of the main switch, and is lifted out of the way by moving the starting lever, 22, to the "off" position, where it bridges the contacts, 20, and thereby makes it possible to excite the shunt magnet, 18. The circuit to the shunt magnet is closed initially through the contacts, 20, and the extended jaws, 25, into which the auxiliary switch blades, 19, can be

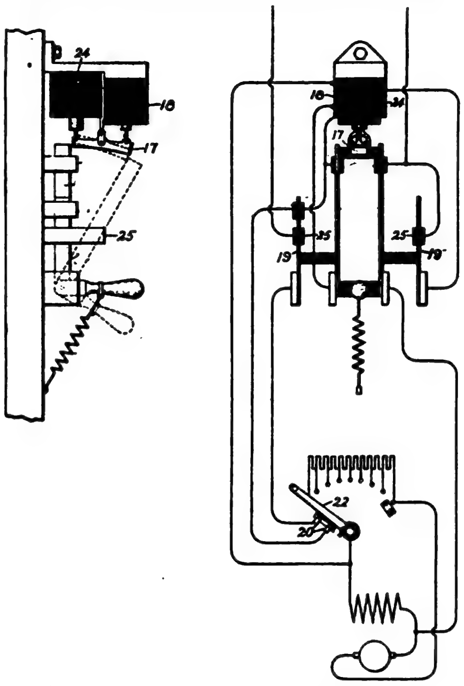

FIG. 1.—MOTOR-STARTING RHEOSTAT.

set before the main blades reach the stop, 17. After the main switch is once closed, the magnet, 18, remains in circuit regardless of the contacts, 20. The starting lever, 22, is provided with a spring to prevent its being left in an intermediate position, and is held in the running position by a friction clip or jaw located near the extreme right-hand button. Patent No. 786,017.

Printing Press Motor Controller.—It is well known to those at all familiar with the practical operation of large printing presses that when such a press is equipped with individual drive, means must be provided for turning the press very slowly—at a mere crawl—during the process of "making ready" or for threading in the paper of a perfecting press, as well as means for driving the press at ordinary speeds. One of the difficulties encountered in meeting these requirements with electric motor drive is that a motor large enough to drive the press at full speed cannot be controlled with absolute reliability at "crawling" speeds unless some very complex control system be employed; the remedy for this is to use a small motor for "threading" and "inching" and a large one for normal running, and this plan was adopted some years ago by the Cutler-Hammer Manufacturing Company, Milwaukee. With two motors, however, some difficulty has been experienced in shifting from the small to the large machine when driving a perfecting press; any sudden change in speed almost invariably tears the paper and makes it necessary to "thread up" all over again. In order to avoid this contingency, and to accomplish other desirable objects which will develop in the following explanation, Mr. H. H. Cutler, of the Cutler-Hammer Co., has devised the arrangement indicated by the accompanying diagram, Fig. 2.

The large motor, 26, is either coupled or geared positively to the driving shaft of the press and the small motor, 2, is connected to the shaft of the larger one through a magnetic clutch, 9, and reducing gears; the gears are required in order that the small motor may run at a rational speed while the press "crawls." The operation of the motors and controlling apparatus is as follows: When the rheostat lever, 31, is moved to the first contact, it also touches the contact, 71, and short-circuits the lamps, 69, which were in series with the solenoid, 65, and prevents it from lifting its plunger (this solenoid is always in circuit as long as the main switch, not shown, is closed, and the plunger of the solenoid, 51, is down). The solenoid, 65, immediately lifts its plunger and closes the circuit through the magnetic clutch, 9, thereby coupling the small motor to the press through the gears and the large motor shaft; the finger, 74, is lifted by the solenoid plunger, re-inserting the lamps, 69, in series with the winding, which is strong enough to hold up the

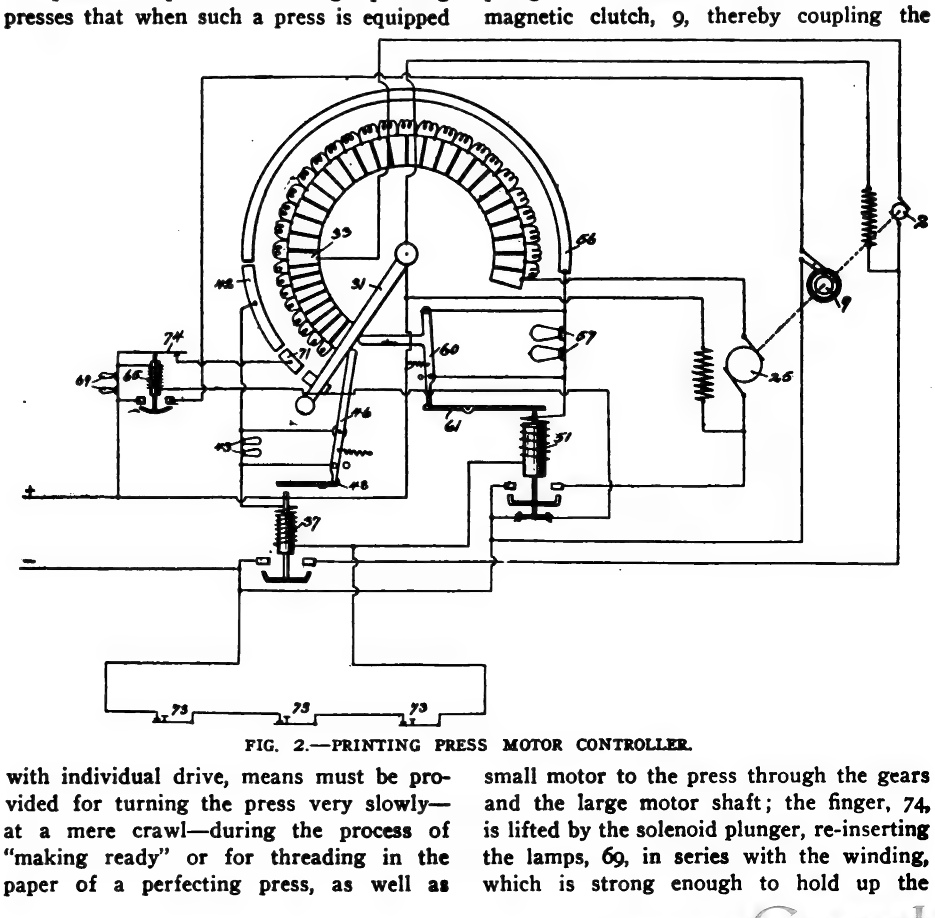

FIG. 2.—PRINTING PRESS MOTOR CONTROLLER.

plunger with the reduced current, but not to lift it from its lowermost position.

Further movement of the lever, 31, puts it in contact with the segment, 42, causing the solenoid, 37, to be energized and to close one side of the circuit of the small motor, which is closed on the other side to the armature through the rheostat and to the field winding direct. The motor starts up, and its speed is regulated by the rheostat up to the contact, 33, at which point it runs at its full speed. The plunger of the solenoid, 37, when drawn up as described lifts the latch, 48, and releases the lever, 46, which is pulled over by its spring and removes the short-circuit around the lamps, 43, putting them in series with the solenoid winding. Movement of the rheostat lever, 31, beyond the contact, 33, causes it to leave the strip, 42, thereby opening the exciting circuit of the solenoid, 37, and causing it to open the circuit of the small motor; just before doing this, however, it closes the circuit of the solenoid, 51, by touching the strip, 56, and that solenoid closes one side of the circuit to the large motor, the other side of which is already closed to the armature through the rheostat and to the field winding direct, as a tracing of the circuits will readily show. When the solenoid, 51, lifts its plunger, the lower contacts are opened, thereby opening the exciting circuit of the solenoid, 65, and cutting off the magnetic clutch, 9. This, of course, leaves the large motor driving the press, with the small one disconnected both mechanically and electrically; the rheostat and motors are so designed that when the large machine takes hold the press speed is practically the same as that given by the small motor when at its maximum, so that there is no jerk in the transition from one to the other. The large motor is brought up to full speed or any intermediate speed by further movement of the rheostat lever in the ordinary manner. When the solenoid, 51, lifted its plunger, it raised the latch, 61, allowing the lever, 60, to remove the short-circuit on the lamps, 57, and put them in series with the solenoid winding.

For stopping, one of the push-buttons, 73, is depressed, opening the exciting circuit of the solenoid, 51, and cutting off the large motor. Since lamps are in series with the solenoids, the motors cannot be put in circuit again by merely releasing the push button, 73, the solenoids being too weak to lift their plungers from the "off" position, though strong enough to retain them when once lifted. Before starting up again, therefore, the lamps must all be short-circuited, and this is accomplished automatically by swinging the lever, 31, back to the zero position, when it strikes the levers, 46 and 60, restoring them to the short-circuiting positions, where they are held by their respective latches. Patent No. 786.421.

CENTRAL STATION ENGINEERS.

VIII.

Paul Doty.

The subject of the present sketch was born in Hoboken, N. J., on May 30, 1867. After his graduation from the Stevens Institute of Technology in 1888 he entered the employ of the United Gas Improvement Company of Philadelphia, as a cadet engineer. In January, 1889, he was appointed assistant engineer of the Paterson Gas Works, acting at the same time as assistant engineer at the Jersey City Gas Works on special distribution work and construction. He afterwards returned to

PAUL DOTY.

the Paterson Gas Works and in January, 1890, was appointed assistant superintendent, in which capacity he continued until December, 1895. At that time he was appointed general manager of the newly organized Consolidated Gas Company of New Jersey, a corporation controlling the gas and electric interests in Long Branch and vicinity, including Red Bank and Asbury Park. He continued as manager of the Consolidated Gas Company about two years, when in December, 1897, he was called to represent Mr. Emerson McMillin, a capitalist, in the organization of the gas companies at Buffalo, N. Y. Having satisfactorily accomplished his work in the latter city, he went to Grand Rapids, Mich., as general manager of the gas light company there and in April, 1901, he accepted the position of general manager of the Detroit City Gas Company, Detroit, Mich., and the following month was elected secretary and a director of the company. His aspirations, however, still led him farther West and on September 1, 1903, Mr. Doty became vice-president and general manager as well as manager for the receiver of the Denver Gas & Electric Company, Denver, Colo., which position he still retains. Mr. Doty has been a frequent contributor to the technical press and has read many papers before scientific bodies. He is a member of the American Gas Light Association, Western Gas Association, American Association for the Advancement of Science, American Academy of Political and Social Science, ex-president of the Michigan Gas Association, 1902; member of the American Society of Mechanical Engineers, an associte member of the American Institute of Electrical Engineers, and ex-president of the McMillin Gas Companies' Association. In 1888 he was elected a permanent secretary of the Class of '88, Stevens Institute. Mr. Doty is also a member of many financial and social organizations. Yankee blood of seven generations courses through his veins, he being seventh in descent from Edw. Doty, who was numbered with the Pilgrim Fathers who came over in the Mayflower in 1620.

NOTES.

Brown Coal Operation in Producer Gas Plants.—A rather promising type of suction gas producer for operation with brown coal has been developed by the Deutz Gas Motor Works, and is described as follows: The producers consist of a pit oven open at the top and fitted with a grate below. The supply of air takes place both from the top and bottom, so that two burning ranges are formed. The gas that is evolved is sucked away at about half the height of the pit either by the engine itself or by a special suction blower, conveying it to a reservoir. The fuel that is filled in from above is first reduced to coke by contact with the incandescent coal lying below, after which it drops to the bottom, being completely gasefied in the lower part of the generator above the grate. The products of distillation sinking to the bottom during this process still contain a large quantity of readily condensible volatile hydrocarbons (tars) which are said to be decomposed completely into permanent non-condensible gases on their passage through the upper incandescent coal layer, thus becoming unobjectionable for engine operation. The generated gas is practically free from any tar on leaving the producer, so that all that is left is to separate in some suitable way any dust particles carried along and to cool the gas before it is used in engines. To accomplish this the gas is led through a water-sealed dustbag and a scrubber. It is claimed that in this plant any kind of crude brown coal, with a moisture up to 20 per cent., as well as brown coal briquettes, can be gasefied. According to the water contained by

the fuel, the air entering through the grate should or should not receive an addition of moisture, which by cooling the grate will prevent any objectionable formation of slag and by its conversion into water gas will augment the heating value of the generated gas.

American Society of Mechanical Engineers will hold its annual meeting this year at Scranton, Pa., on June 6 to 9 inclusive. A list of very important papers is announced.

The American Chamber of Commerce, recently established at Naples, Italy, includes among its members some of the largest firms in Italy and this country, so we are advised by the president of the Chamber, Mr. J. P. Spanier. The rooms are located at No. 10 Piazza della Borsa.

The New York Telephone Association.—The annual convention of the New York State Independent Telephone Association will be held on June 16, at Albany, N. Y. The sessions will take place in the Common Council Chamber of the City Hall, and an excellent program has been prepared.

Medina and Its Electric Power Plant is the title of a most attractive book issued by the A. L. Swett Electric Light & Power Company, Medina, N. Y. The company now operates two generating stations (water-driven) and a sub-station, the total output capacity of the generating plant being 3,000 horse-power.

Catalogues Wanted.—The American Consul at Prague, Bohemia, Austria-Hungary, writes that catalogues of American manufacturers of machinery and appliances of all sorts are greatly desired in his locality. All catalogues sent to him are carefully filed and a complete index of the collection is kept.

The National Electrical Contractors' Association will hold its fifth annual convention at Boston, July 15 to 23 inclusive, and there will be an important exhibition of electrical apparatus and appliances in conjunction with this meeting. The exhibition will be held under the auspices of the Electrical Contractors of Massachusetts, and the headquarters will be at Mechanics Building, where 83,000 sq. ft. of floor space will, it is stated, be available. Full information is obtainable from Mr. C. I. Campbell, 5 Park Square, Boston.

An Electrical Show will be held at Madison Square Garden, New York, from December 12 to 23 inclusive, under the auspices of the Exposition Company of America. There has not been an electrical exhibit in this city since the one held in conjunction with the Electric Light Association's convention in 1899, and in view of the strides that have been made since that time there should be available ample material with which to make the coming exhibition well worth while. Detailed information may be had from Mr. George F. Sever, Director of Exhibits, Room 903, No. 26 Cortlandt Street, New York.

International Association of Municipal Electricians will hold its tenth annual convention at Erie, Pa., August 29 to 31. The papers to be presented are as follows: "Electrical Induction, Its Effects and the Application of Methods Used to Counteract It"; "Advisability or Inadvisability of Fusing Fire and Police Telegraph Boxes"; "Suggested Improvements in Fire Alarm Telegraphs"; "Underground Construction"; "The Necessity of a Rigid Inspection by the Municipality"; "Electric Light Engineering"; "Electric Light Plants." These papers have been assigned to men who are thoroughly conversant with the subjects selected, and they are obviously of great importance to municipal electricians.

The York River Power Plant.—The weather being favorable, preliminary work to the erection of an electric power plant on the Susquehanna River, about a mile and a half below McCall's Ferry, has been taken up. This power plant is expected to supply current to Baltimore, Philadelphia and other cities and towns within similar range. The capitalists interested are New Yorkers and Philadelphians, and it is asserted that they already have invested nearly half a million dollars in buying up lands along both sides of the river.

The work of the engineers under Messrs. Eby and Anderson has been delayed during the past year, because of the fact that Mr. Eby was sent to Panama, and that Mr. Anderson, during a trip to his parents in Turkey, was imprisoned for some alleged utterances which were not pleasing to the authorities. Both have since returned to York County.

Substantial Power Plant Construction.—A frightful railroad wreck occurred on May 11, at Harrisburg, Pa., due to the collision of a passenger train with two freight cars loaded with 50,000 pounds of dynamite. The power plant of the Paxtang Electric Company, designed and built two years ago by J. G. White & Co., of New York, is located on the bank of the Susquehanna River, about 150 feet from where the explosion took place, and although more than 1,000 panes of glass were shattered to fragments, covering the generators and other machinery with minute particles of glass, careful examination has failed to show any other damage to the plant, which continued operation uninterruptedly. The force of the explosion may be imagined from the fact that heavy plate glass windows three miles away were demolished by the concussion. Upon hearing of the explosion, J. G. White & Co. immediately telegraphed an offer of any assistance that might be necessary to the electric light company, but none was needed.

A Novel Traffic Indicator.—An interesting apparatus for the indication of telephone traffic is in service at the main office of the Maryland Telephone Company, Baltimore. It consists of several rows of incandescent lamps mounted upon the wall opposite the chief operator's desk, two lamps being assigned to each operator's position. The lamps are 1-3 candle-power each and are operated by the pilot relays on the main switchboard. The upper lamp of each pair is white, and the lower one red. When a subscriber calls the central office the white lamp lights and remains lighted until the operator at that particular position plugs into the subscriber's jack, when it is extinguished. As soon as either subscriber hangs up his receiver the red light begins to burn and goes out only when the operator takes down the connection. By this device the chief operator can see at a glance the service being given on each position and can apportion the work among the different operators so as to avoid over or under loading. In a small monitor room adjoining is a reproduction of the traffic indicator on a smaller scale, set in the front of an expert operator's desk. This operator watches the service continually, going in upon one line and another and correcting defects in the service as occasion arises. The advantage of this method over inspection at long and regular intervals is obvious.

The Electric Light Convention.—As previously announced in these columns, the twenty-eighth convention of the National Electric Light Association will be held in Denver on June 6 to 11 inclusive. The program as thus far arranged is an extremely attractive one, both as to the serious sessions and as to the entertainment features. The business meetings will begin in the ballroom of the Brown Palace Hotel, Denver, on the morning of June 6. Entertainment and business sessions will continue until the night of June 8, and on the following morning those attending the convention will go to Colorado Springs for three days of entertainment. The following suggestions regarding railroad tickets may be of value: On the Union Pacific, Burlington and Rock Island roads tickets should read through Denver to Colorado Springs with stopover at Denver; on the Santa Fe and the Missouri Pacific they should read through Colorado Springs to Denver, with stopover at Colorado Springs on the return trip. This does not entail any extra expense; the railroads have agreed to the stopover. Low rates have been obtained, but they may go lower. Any of the three roads between the two cities gives good service. The scenery along the Short Line is superb, and as the train climbs the grade the visitors will be able to view the scenery for a distance of 100 miles. The big producing mines of Cripple Creek and the best of the electrical stations will be visited Those who desire to take the trip to Pike's Peak may do so on Sunday. This will be an optional trip, as will others that one may take to dozens of points of interest in and around Colorado Springs.

ESTABLISHED 1889.

AMERICAN ELECTRICIAN

WITH WHICH IS INCORPORATED
Electrical Industries.

CECIL P. POOLE, Editor.

Issued on the first of each month by the

McGraw Publishing Company

Chicago Office ....Monadnock Building
Cleveland Office ....Cuyahoga Building
London Office, Hastings House, Norfolk St., Strand

Address all business communications to AMERICAN ELECTRICIAN, *114 Liberty Street, New York. Matter intended for publication in the reading columns should be addressed to the editor.*

Subscription price, $1 per year, postage prepaid, in the United States, Canada, Mexico and Cuba; $2 in all foreign countries. The date on wrapper shows when subscription expires. Subscribers should give their old as well as their new address when requesting a change in address. This should be received a week in advance of the desired change. No copies are kept on sale beyond fifteen months from date of issue, except in bound volumes.

Advertising rates sent on application. Advertisements received for insertion up to the 25th of the month prior to date of publication. Changes in standing advertisements should be received not later than the 15th of the month to insure their insertion in the next issue.

Remittances should be by check, New York draft, express or postal money order, payable to AMERICAN ELECTRICIAN.

Entered in the Post Office at New York as second class mail matter.

Vol. XVII. JUNE, 1905 No. 6

The AMERICAN ELECTRICIAN *has the largest circulation of any electrical journal published. Of this issue, 20,000 copies are printed. The total number of copies printed so far this year is 112,000, or an average of 18,666 per issue.*

Switchboard Illumination.

The proper illumination of a switchboard would seem to be one of the simplest questions to settle in laying out a small central station or an isolated plant, but a casual inspection of even recent installations will show that in many instances the subject has received but little thought on the part of whoever laid out the station. Switchboard lighting is of much more importance than might appear at first thought. The economical adjustment of the plant equipment to the load requires frequent reference to the switchboard instruments, of course, and it is essential that the illumination of them shall be bright enough and sufficiently concentrated to enable the attendant to see what they indicate without having to go to the board or even very near it. This is particularly true in plants of moderate size which are not justified in employing special attendants for switchboard work only, and in such plants poor illumination of the switchboard usually results in chronic carelessness as to the adaptation of the generating equipment to the requirements of the load. Since the steam consumption of a single-valve, high-speed automatic engine ordinarily increases from 30 per cent. to 40 per cent., at one-quarter load as compared with full-load consumption, it is important that wide changes in load should be noted promptly, and the influence of inadequate illumination of switchboard ammeters in discouraging continuous supervision of the load condition is really much greater than is commonly realized.

To a certain extent the illumination of switchboard apparatus is a problem very similar to that of lighting a picture gallery, and it should be treated separately from the lighting of the generating room, except that the latter should be so designed that the precautions for efficient lighting of the board will not be partly or wholly nullified. The best practice, of course, is to provide an individual incandescent lamp for each instrument scale and each circuit-breaker and a sufficient number to illuminate satisfactorily the other equipment on the board, all of the lamps being shaded on all sides except that next to the board. This advice will seem actually trite to many readers; nevertheless, plants have been very recently installed in which these simple precautions were not observed fully. In one case a 16-c.p. lamp was mounted on a bracket between each pair of ammeters throughout the length of the board, but where the panels joined the brackets were omitted. The results were that one-half of each ammeter scale was indifferently illuminated and the other half so shaded as to be unreadable from an appreciable distance.

The size of lamp suitable for switchboard illumination naturally depends on the size and arrangement of the apparatus, and to some extent on the material of which it is made—or perhaps more accurately, the finish put on that material. For individual lighting, an 8-c.p. lamp will usually suffice, and for general illumination of switches, etc., 16-c.p. lamps will always be large enough if intelligently distributed. The material and finish of the switchboard panels have a conspicuous effect on the efficiency of the lighting. In large plants of recent design a notable advance in this respect has been made in the use of panels finished in dull black instead of highly polished fronts of white or pink marble; the latter may look very pretty to the officials of the company on inspection tours, but they are most trying to the eyes of the men who have to look at them day after day—or night after night.

The Value of Electric Signs.

The Edison Electric Illuminating Company, of Boston, recently pointed out that the number of electric sign users in that city had increased more than three-fold within a period of eighteen months, and stated that its experience had conclusively demonstrated that the installation of one attractive sign in a neighborhood previously devoid of them invariably results in the installation of several more within a month after the first one starts up. This is due not merely to the power of example but also and largely to the fact that plentiful illumination brings trade to a mercantile establishment; stores that fail to keep up to the times in the matter of electric signs usually find it imperative to "come around" ultimately in order to prevent their progressive competitors from monopolizing their line of trade.

It has also been the experience and observation of the Boston Edison experts in this branch of work that in most cities and towns where the municipal restrictions as to electric signs were originally severe to the verge of being prohibitory the introduction of a few signs has revolutionized the sentiment of the city officials by reason of the conspicuous value of such installations to the city. Electric signs not only make the streets more cheerful and the business localities more attractive, but they serve to

discourage petty criminals from plying their vocations in the districts which would otherwise be the most profitable to them, the illumination being such a near approach to daylight as to make the conditions practically identical with those of the sunlight period.

In view of the foregoing facts, it would seem to be a good policy for central stations which have not exploited the sign feature to make special concessions in order to get the initial installation made. It should not be overlooked, however, that the after success depends almost entirely on the effect produced by the first sign; therefore, this one should be designed and installed with the utmost care. The design should be a strikingly attractive one without going beyond the limits of good taste, and every known precaution should be taken to make its operation reliable; an electric sign with an occasional lamp dark, or one that fails to light up at a critical time, is worse than none at all.

A Common Fault in Plant Layout.

Admirable as is the design of many a piece of engineering work in general conception and larger details, it is frequently true that the results fall short of what the designer probably expected because of the failure to recognize in advance that the highest economy of any installation of machinery, no matter how modern, cannot be obtained unless the layout is consistent throughout. This is frequently demonstrated in manufacturing establishments, for example, where a magnificent equipment of the most modern machine tools may be seriously handicapped by inadequate hoisting or conveying facilities, or by skimpy provision in even more minor details of the shop equipment. An actual case in point, but in another line, is that of a modern printing establishment in New England where each press is individually driven by an electric motor, and hundreds of dollars have been expended in order to obtain the advantages of motor drive. But instead of securing the full measure of cleanliness obtainable by the use of motors, as well as the maximum efficiency of the pressroom force, by lighting the premises electrically, the original gas jets have been retained to make life miserable in warm weather and prevent the ceiling from remaining white. Moreover, the fuse-blocks of the motors are in the basement instead of at conveniently accessible points in the pressroom, the wiring is exposed at the machine terminals and the switches are located at heights of two to five feet above the floor, with no coverings whatever. Many of the possibilities of such an installation in the way of unnecessary delays may be imagined, but a full realization of them is possible only in practice.

Minor Conveniences in Stations of Moderate Size.

There are several ways in which the work of attendants in sub-stations and medium-sized central stations may be facilitated and to some extent improved without involving the outlay of much money. For making out reports, filling in record blanks, etc., for example, a small table with a lockable drawer is far superior to the usual pine desk with a raising top, or the swinging shelf against the wall, and will always increase the employee's interest in his work. Liberal locker accommodations for the street garments and small personal effects of the employees will also prove a most profitable investment. The location of the telephone in a sound-proof and ventilated booth is a precaution which is of no little importance, to say nothing of the convenience to the station attendants who have to use the instrument; failure to hear promptly instructions telephoned to a station or information telephoned from it may easily cause a delay costing more money than a dozen of the finest booths that can be built. A small three-wheeled truck and a portable hoist for handling armatures, transformer parts, etc., should be in every station, no matter how small; the increased facility of handling an armature in a single emergency might prove an ample return on the difference in the first cost of such an equipment as compared with the usual chain hoist, intended to be "hung up somewhere" when needed. Excepting the telephone booth and the hoist, these conveniences are relatively small matters, but they will contribute a great deal to the contentment and efficiency of the employees, and their cost is insignificant in comparison with the results obtainable through them.

Concerning Name Plates.

So far as its operation is concerned, a dynamo or motor would be just as well off without a name plate as with one; yet there is probably no other part of the machine that is examined so carefully by visistors to a station or other interested persons not employed therein. And it is a matter of reasonable pride to the electrical engineer, being an indication of the thoroughness and precision with which his work has been done, that every piece of revolving and transforming apparatus for which he is responsible carries upon it this certificate of output ability, voltage, current, speed, etc. Of course, this is not the reason that name plates are put on dynamos, motors, converters, transformers, etc.; the chief object is to inform everyone interested in the matter just what the apparatus is intended to do, what its maximum output ability is and who made it (possibly the last-mentioned point should have been put first in the list). This method of imparting the information mentioned is not employed solely for the benefit of casual visitors, either; it is of prime importance to the operating staff of a station. It is not rational to expect employees to memorize the characteristics of every machine or important piece of apparatus about the plant, although most of them in time do so involuntarily, and it is highly essential that the fundamental data relating to any piece of apparatus shall be immediately available when required; the name plate meets this requirement perfectly—when it is properly made.

The foregoing argument applies just as forcibly to steam apparatus in an electric lighting or power plant as to the electrical equipment, yet no one ever saw a boiler name plate on which was stamped the number, diameter and length of the tubes, size of the grate, total area of heating surface, evaporating ability, etc.; nor does an engine name plate give the sizes of the cylinders, most economical point of cut-off, rating in pounds of steam per horse-power-hour at this cut-off and a stated initial pressure, or any other technical information beyond the so-called horse-power and preferred speed. In the case of pumps, the makers have gone a little farther ahead as to name plates and usually put on the cylinder sizes; it would be of considerable assistance to the user if the capacity in gallons per minute at the preferred speed were also put on, and the pressures for which the pump is designed might advantageously be included. The name plates on pumps for fire service are models of satisfaction in these particulars.

The point is that a great deal of valuable time is often lost by having to hunt up or calculate data which ought to be plainly stamped on the name plate of a piece of machinery; moreover, in the handling of machines equipped with incomplete name plates mistakes are made which would easily be avoided otherwise and which in some cases cause the machine to suffer disastrously for the petty sin of its builder.

HOW TO MAKE AN ELECTRIC BUCKBOARD.

BY J. C. BROCKSMITH.

The vehicle here described is of the buckboard type, in which the necessary cushioning effect usually obtained by means of springs is secured, partly through the resiliency of the tires and partly through the use of a frame or platform which gives a considerable elastic deflection under load. This permits of dispensing with springs and results in a much simpler and lighter construction all the way through.

A single motor is used in connection with a differential or balance gear of simple construction on the rear axle. Owing to the extreme lightness of the vehicle and the consequent small power required to run it, it would be inadvisable to subdivide the power into two units with a resulting loss in efficiency.

The battery used consists of 20 double cells, each having a capacity of 20 ampere-hours, thus giving 80 volts and 20 ampere-hours when coupled in series.

The controller provides three forward speeds of 3½, 7 and 12-14 miles, and a slow speed reverse of 3½ miles per hour with the normal gear ratio. At the normal speed of 12-14 m.p.h. the machine is capable of running 35 to 40 miles on one charge of the battery, over good roads. With a change of driving sprocket any speed up to 20 or 25 m.p.h. can be obtained without exceeding the one hour discharge rate of the battery. Higher speeds than the normal are only obtained, of course, at the expense of efficiency which results in a lower mileage due to the high discharge rate of the battery.

The outfit is designed particularly for city use over well-paved streets and with this in view the weights of the various parts have been reduced to the lowest possible limits. The weights of the various items and of the complete vehicle are as follows:

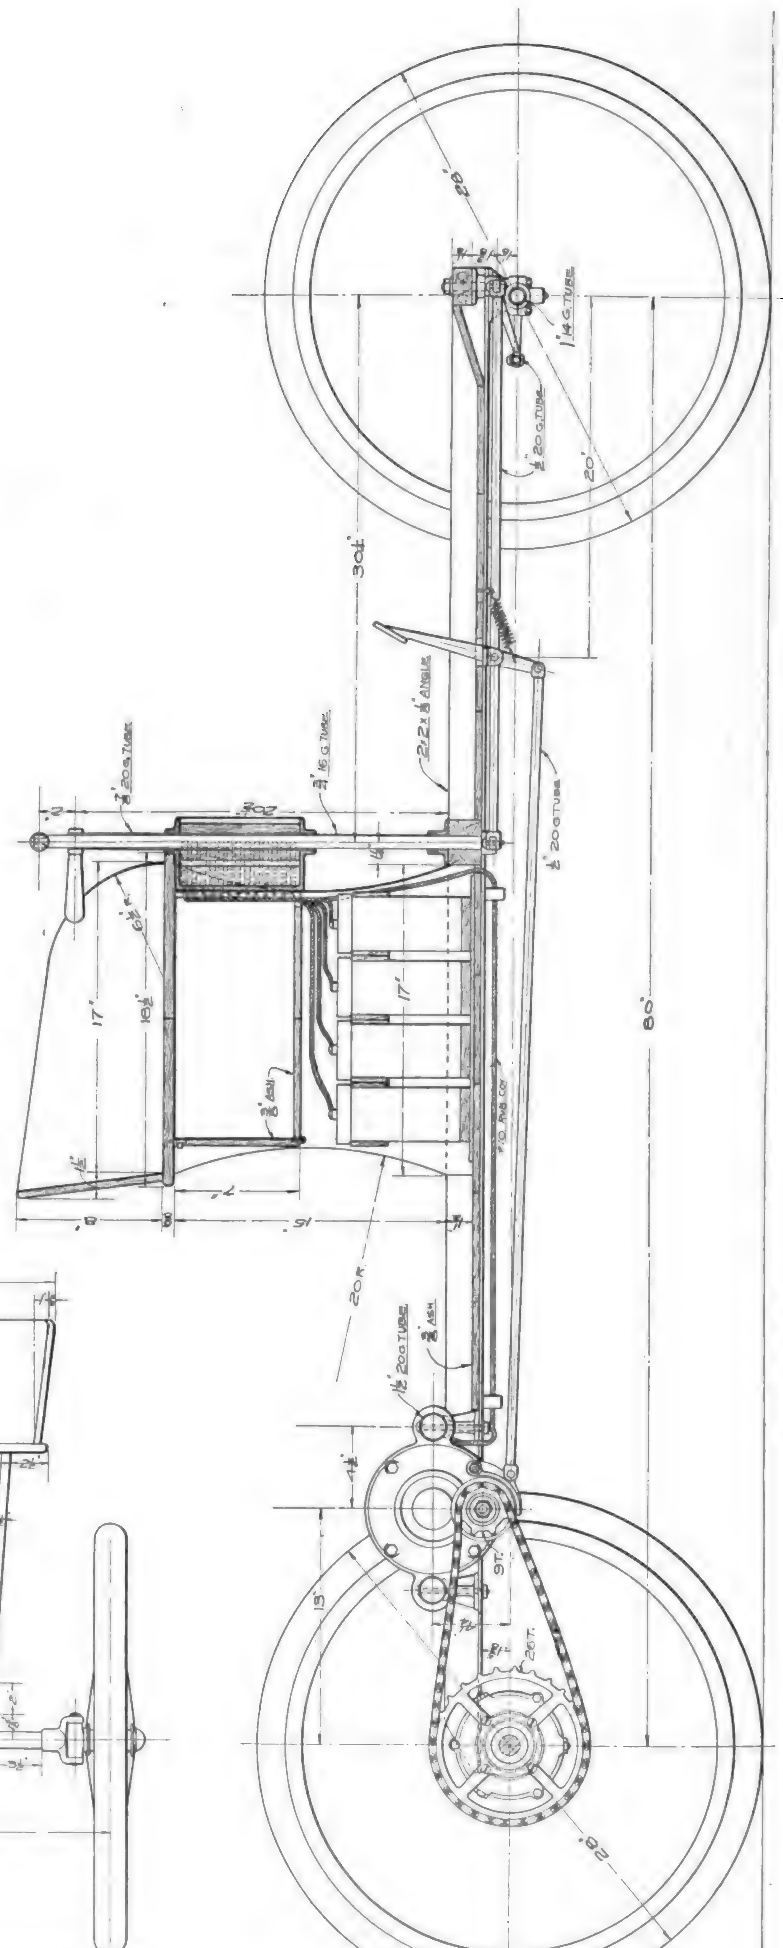

FIG. 1.—SECTIONAL ELEVATION OF ELECTRIC BUCKBOARD.

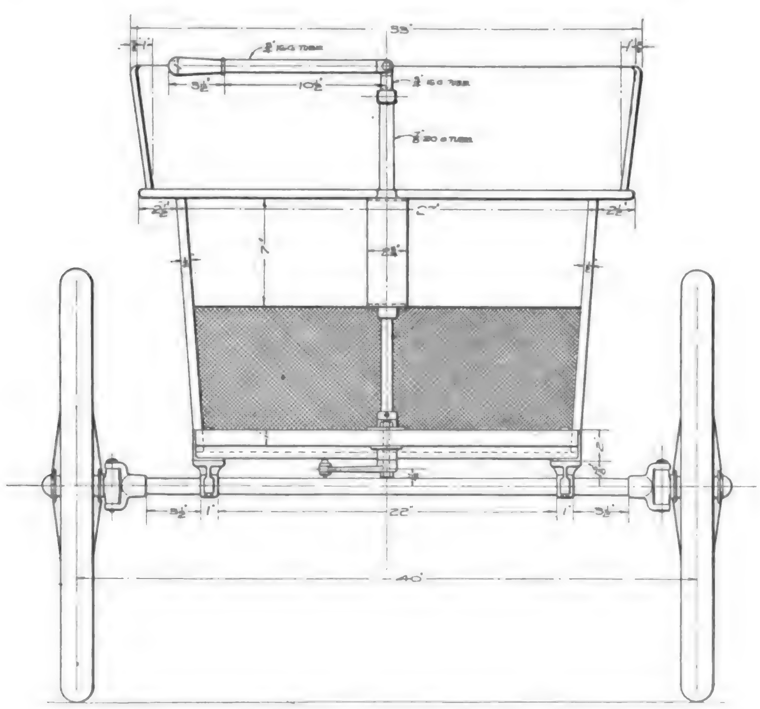

FIG. 3.—END ELEVATION OF BUCKBOARD.

Motor	38 lbs.
Battery	170 lbs.
Running gear	122 lbs.
Woodwork	45 lbs.
Total	375 lbs.

The Running Gear.

Fig. 1 is a sectional elevation of the complete buckboard and shows the mounting of the motor on the frame together with the method of driving by means of gears and chain reduction to the rear axle.

The wheels are 28 inches in diameter provided with 2-inch, single-tube, "motor cycle" tires and have 36 and 40 spokes of 12 and 14 gauge. The rims are of 28 x 2 maple. The "body" consists merely of a seat accommodating two persons, the space underneath being divided into two compartments by a horizontal shelf. The lower compartment is for four battery trays, while the upper compartment may be utilized for storing a tire pump, charging cable and such tools and accessories as may be required.

The controller, which appears in Fig. 24, is a small semi-cylindrical affair mounted on the front of the seat. The steering rod passes up through the controller cylinder and terminates in a steering handle or bar at a convenient distance above the floor line, the controller itself being operated by means of a smaller handle located concentrically with and just underneath the steering handle.

The brake pedal is located within easy reach of the operator's foot and connects with a brake shoe working on a drum on the motor counter-shaft, which, being geared, as it is, to the rear axle in the ratio of about 3 to 1, makes a very effective brake. As an extra precaution in case of emergency, the motor may be run in the reverse direction, but this is not advisable ordinarily as it puts a severe strain on all the transmitting parts.

It is hardly advisable to install any electrical instruments on a vehicle of this description as it increases the cost and also the wiring complications. It is well to have a small cyclometer of the "trip" type on the front wheel; this will enable the operator to keep within the known mileage capacity of his battery. It is useful to test the vehicle when first completed for speed, current consumption, etc.; but after such data are obtained there is no further necessity of having instruments on the machine. The tests should show up about as follows:

Controller.	Volts.	Amps.	Speed. M.P.H.
1	21½	5½	4½
2	41	7	9
3	80	9	15

Fig. 2 is a plan view of the chassis and shows the steering and brake connections, together with the motor suspension and drive, somewhat more plainly than in the previous figure.

The two side members of the frame are composed of 2 x 2 x ⅛ inch steel angles. These are figured to work well up to their elastic limit under load and consequently give a considerable elastic deflection which contributes to ease of riding. The angles are cut off 83 inches long and are drilled

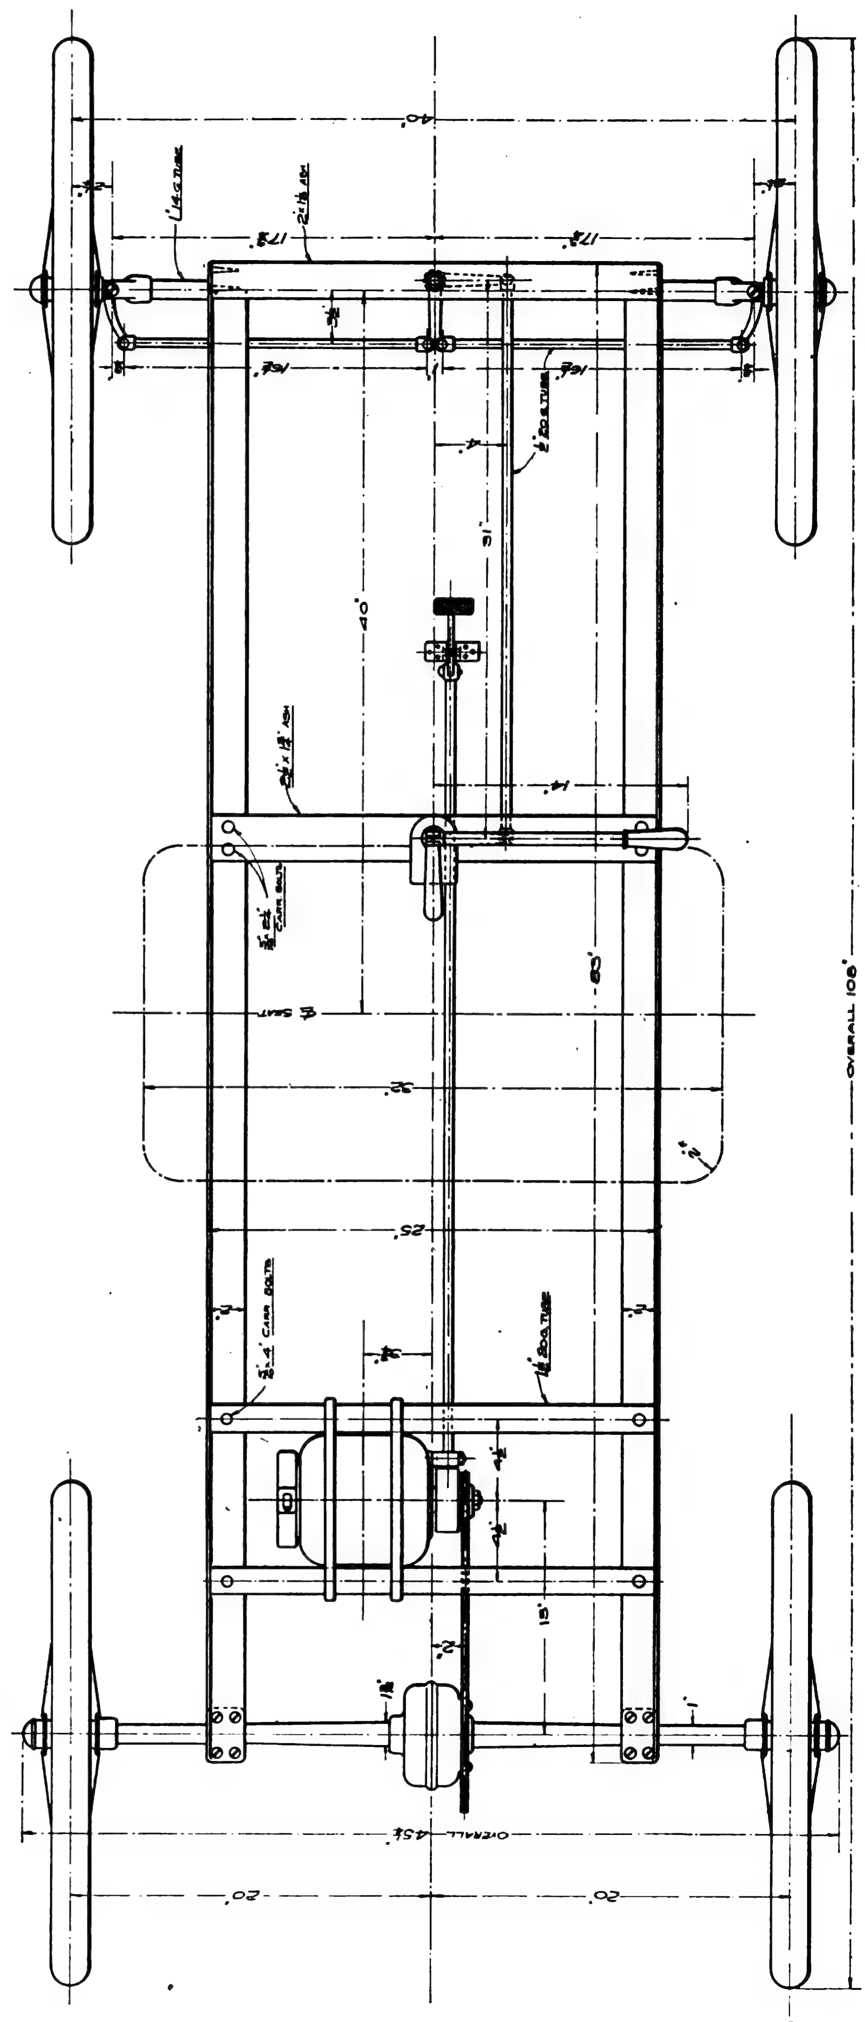

FIG. 2.—PLAN VIEW OF CHASSIS.

at each end for four 5/16-inch machine screws, which fasten on the axle bearings. They are also drilled and tapped at intervals to fasten the flooring, which is laid directly on the lower flanges of angles and secured by means of 10.24 flat head machine screws tapped into the metal.

Cross pieces of ash are provided at the front and near the center to serve as supports for the steering connections. Toward the rear there are two cross bars of 1½-inch 20 gauge steel tubing which support the motor. All of these cross pieces are bolted to the frame with 5/16-inch carriage bolts, the frame being drilled with holes properly located to receive them.

The motor must be located somewhat off the center, of course, in order to allow the differential gear to be placed in the center of the axle. Fig. 3 is a front elevation of the buckboard showing the location of the steering knuckles and controller, etc., and contains some dimensions relating to the seat which do not appear in other views. The front of the battery compartment under the seat should be covered with a screen of wire cloth or perforated sheet

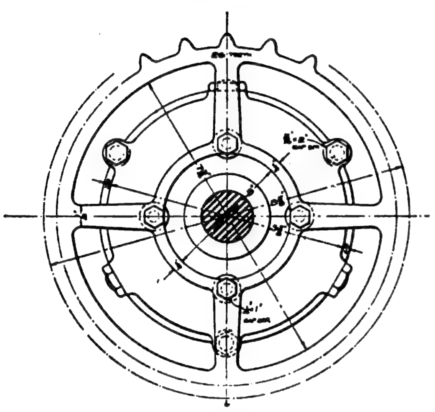

FIG. 5.—END VIEW OF DIFFERENTIAL GEAR AND SPROCKET.

metal, which permits ventilation of the battery and presents a finished appearance. The metal should, of course, be well painted to prevent corrosion.

Fig. 4 shows a semi-sectional view of the rear axle. The most satisfactory material out of which to make the axle is a bar of 1¼-inch nickel steel. The center portion is turned down to 1 3/16 inches, tapering to 1 1/16 inches just inside the bearings. From the bearings to the hubs the size is 1 inch. The bearings are of a standard size and type which can be purchased from any-one of several makers of ball bearings and are of the "grooved shaft" type, consisting of a tool-steel spool slipped over the shaft and two hardened rings fitting the case, one of which is threaded for the purpose of adjusting the bearing; 11/32-inch balls are provided in this size of bearing and these are satisfactory for the load and speed used.

The method of fastening the hub on the axle will vary somewhat with the type of hub selected. In cases where good-sized tandem or quad hubs are used, these are made threaded for a sprocket. A steel cap is made to fit this thread, the cap in turn being pinned to the axle. The axle within the hub is turned to fit the holes in

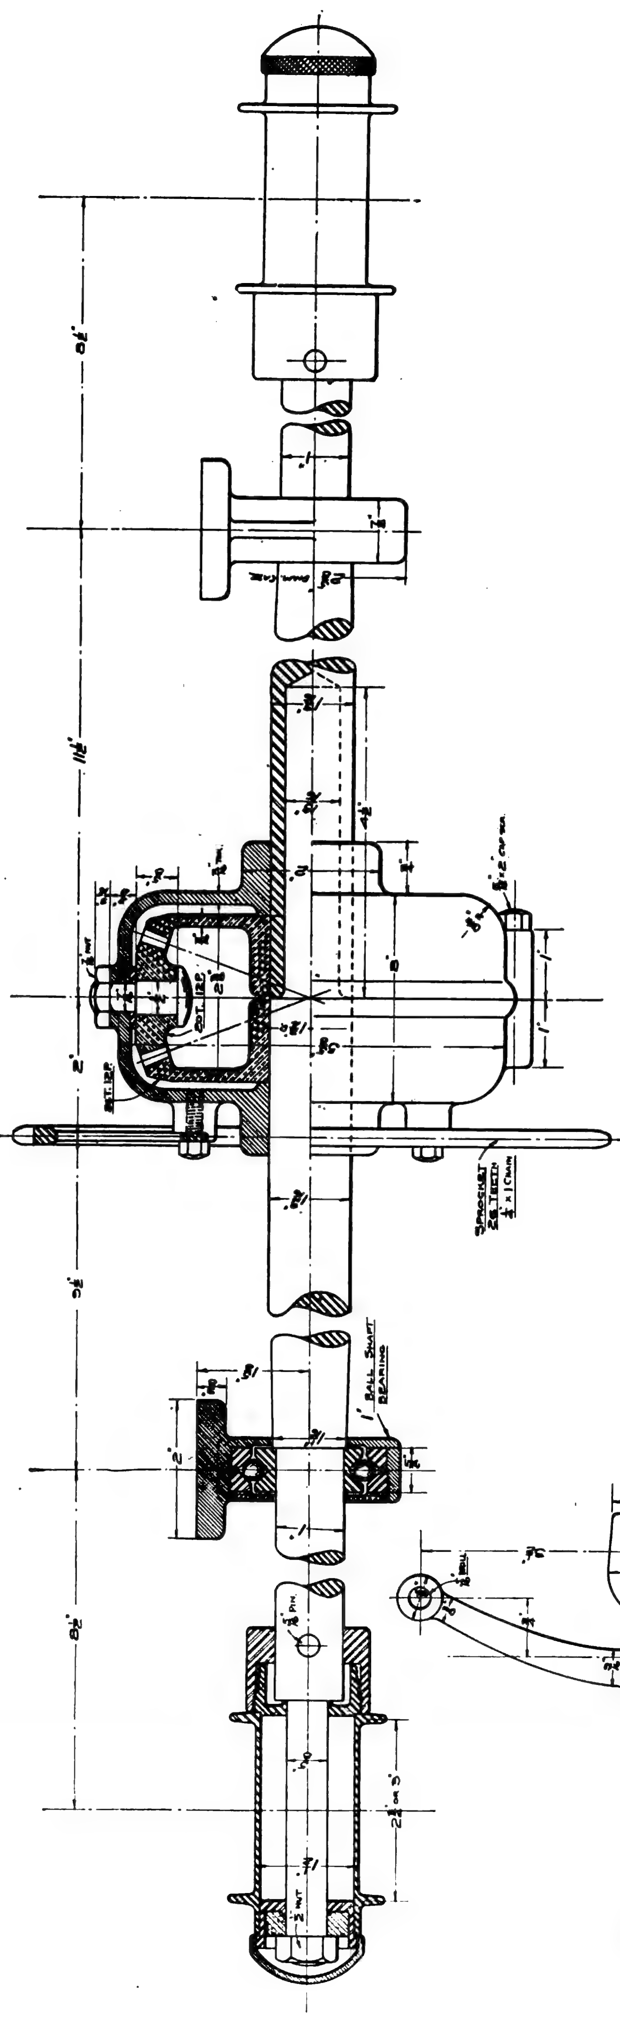

FIG. 4.—SEMI-SECTION OF REAR AXLE AND DIFFERENTIAL GEAR.

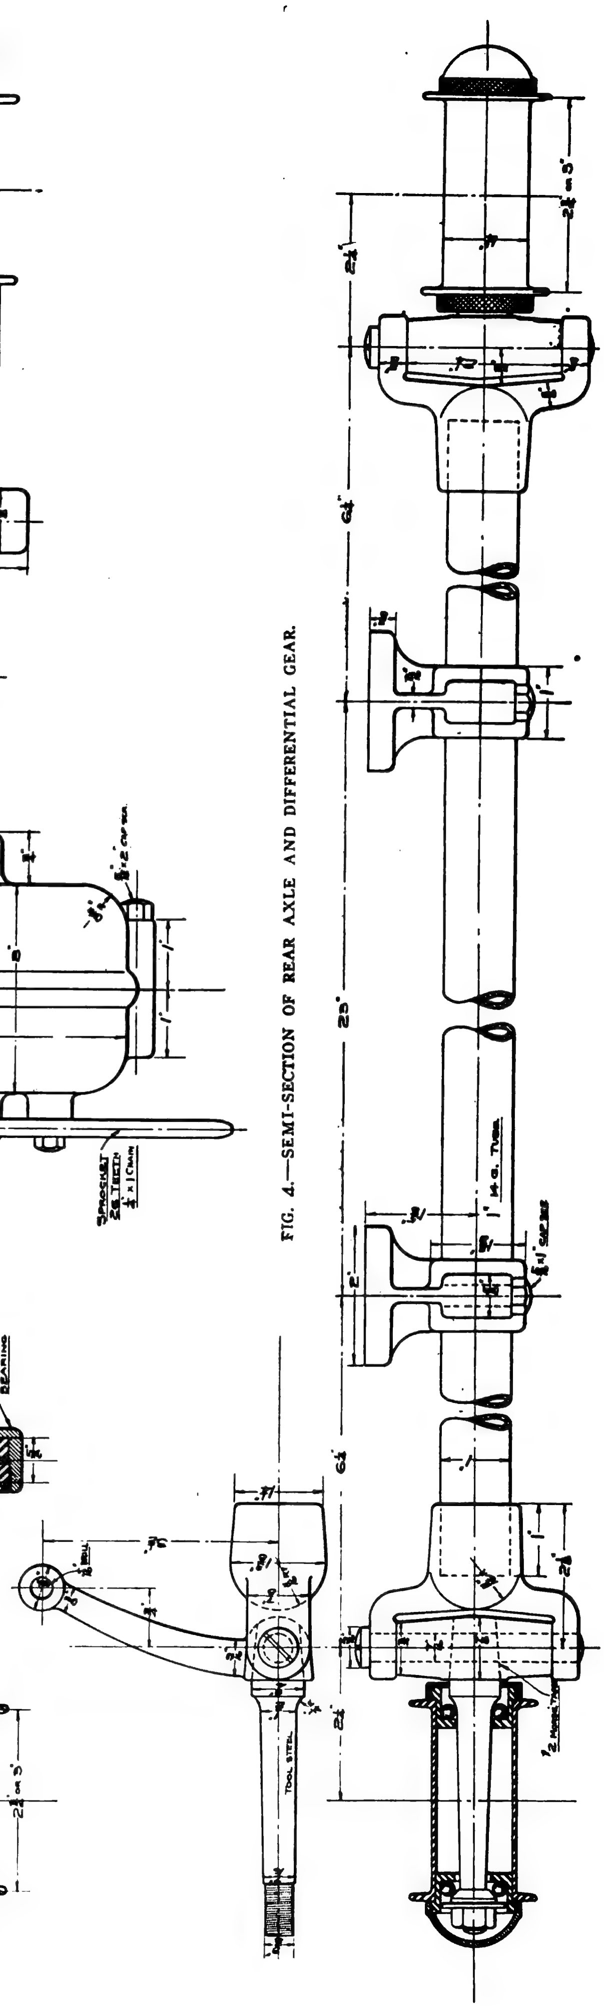

FIG. 6.—DETAIL OF FRONT AXLE.

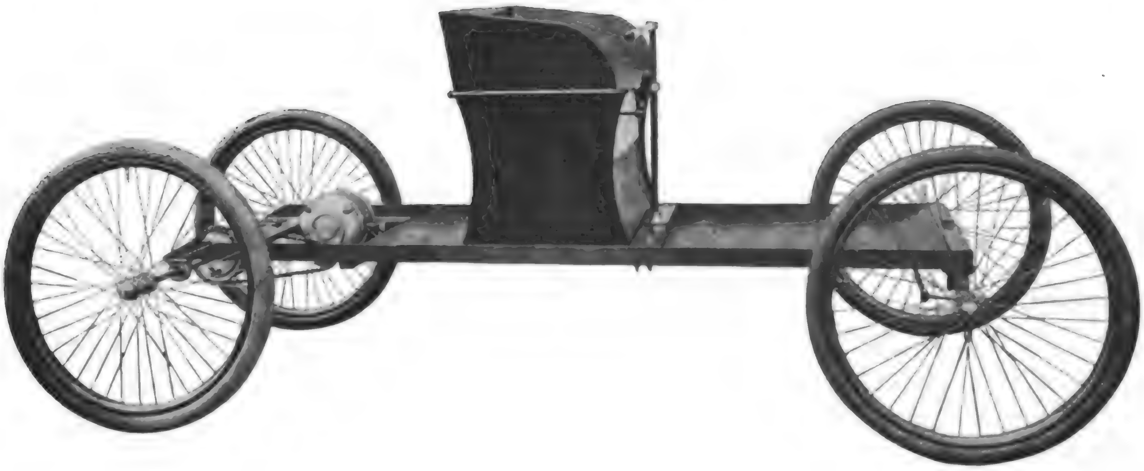
the ball cups and provided with a nut and washer at the outside end.

In the center the axle is, of course, divided, one-half being turned down to 13/16 inch, which fits into a bored hole in the other half 4½ inches deep. Each half axle has a bevel gear keyed to it, which meshes with three bevel pinions secured on studs projecting through the gear case. These gears should all be cast of good phosphor-bronze and need not have cut teeth, cast teeth being good enough, providing, of course, that a good metal pattern with cut teeth is used.



SIDE VIEW OF ELECTRIC BUCKBOARD.

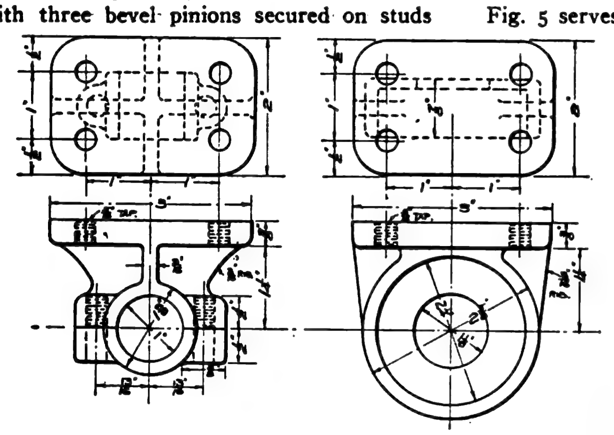


FIG. 7.—DETAILS OF FRONT AND REAR AXLE FITTINGS.

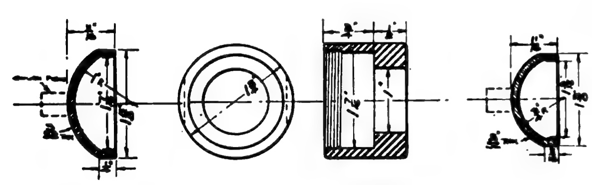

FIG. 9.—DETAILS OF HUB CAPS.

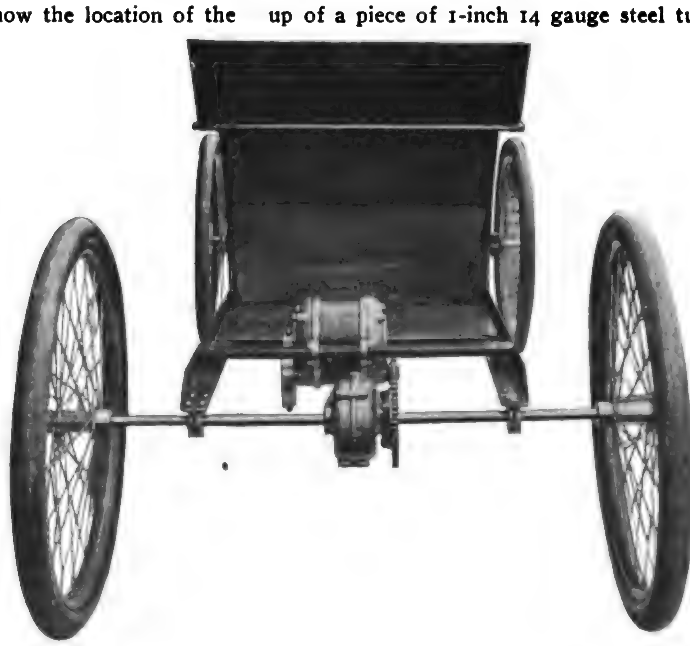

REAR VIEW OF ELECTRIC BUCKBOARD.

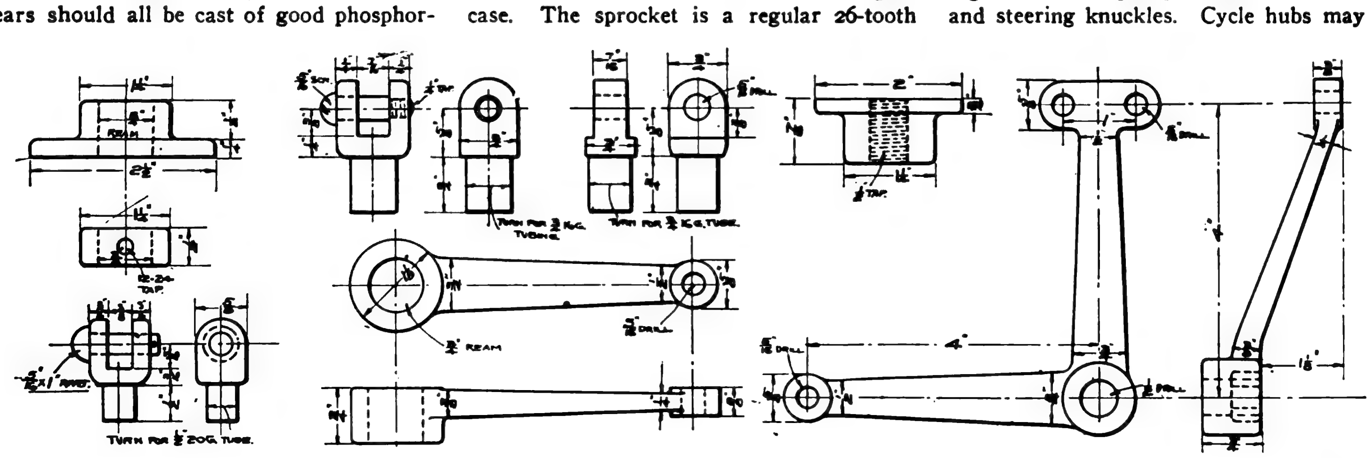

FIG. 8.—DETAILS OF STEERING GEAR CONNECTIONS.

The differential gear case is cast from aluminum alloy containing about 25 per cent zinc. It is provided with lugs at the side for bolting on the sprocket, and there are lugs on the periphery for bolting the two halves of the case together and also to form seats for the pinion studs.

Fig. 5 serves to show the location of the various bosses on the outside of the gear case. The sprocket is a regular 26-tooth bicycle sprocket with four arms and open center for ¼ x 1-in. chain. It has four holes for attachment to the pedal, but these are utilized in the present case for fastening it to the gear case. The most satisfactory chain to use in connection with this machine is one having nickel steel side links and hardened steel blocks and pins. Any chain of ordinary soft steel soon stretches and wears so as to be unusable.

Fig. 6 shows the front axle. This is built up of a piece of 1-inch 14 gauge steel tubing fitted with phosphor-bronze axle ends and steering knuckles. Cycle hubs may be used, a hub being selected which has a 7/16-inch axle. The cups on one side are reamed out to pass a half-inch rod. One-quarter-inch steel balls are used. The bear-

ing portion of the axle is turned from a ¾-inch bar of tool steel and the portion on which the balls run is hardened while the rest should be of much lower temper. The end of this axle stub is turned taper and fitted to the casting portion. The hubs are preferably of a type having the ends threaded for dust caps.

Fig. 7 shows the detail of front and rear axle bearing castings. Cast iron will answer for these, although malleable iron or steel would be better. The rear axle cases are bored and threaded to take the steel ball cones, and the front axle fittings are simply bored one inch and clamped in position on the tube by means of a couple of 5/16-inch cap screws. If tolerably smooth these castings need not be finished on top, where they are screwed to the frame. Four holes are drilled and tapped 5/16 inch for this purpose.

Fig. 8 gives the details of a number of small parts all relating to the steering gear. Their use and location will be seen from an inspection of the general drawings of the machine. These are all made of phosphor-bronze, and one is required of each except in the case of the small jaw casting, of which eight are wanted. There need not be any finish allowed on any of these castings except where as indicated on the drawing they are to fit the inside of tubing.

Fig. 9 shows the hub caps, which are made of the same aluminum alloy as the differential gear case and are finished bright. The steel caps for driving the rear hubs have already been described in connection with the rear axle.

The following is a list of the steel stock required to construct the running gear:

No. wanted.	Material.	Wanted for.
2 pcs.	83.2"x2x⅛ angle.	Frame.
1 pc.	50"x1¼" nickel steel.	Rear axle.
2 pcs.	4¾x¾ tool steel.	Front axle ends.
2 pcs.	15½"x½" 20G. tubing.	Steering gear.
1 pc.	30"x"½ 20G. tubing.	Steering gear.
1 pc.	28½"x¾" 16G. tubing.	Steering upright.
1 pc.	14½"x½" 20G. tubing.	Controller sleeve.
1 pc.	9¾"x¾" 16G. tubing.	Steering handle.
1 pc.	33½"x1" 14G. tubing.	Front axle.
1 pc.	43½"x½" 20G.	Brake rod.
2 pcs.	24¾"x1½" 20G. tubing.	Motor supports.

SOME THINGS ENCOUNTERED IN POWER PLANTS.

BY WM. CAVANAGH.

Upon taking charge of a going plant, an engineer usually wonders how "the other fellow" ever ran the equipment in any sort of satisfactory manner. However, now that he is in charge, he feels the obligation to put things in good running condition. One of the curious things he may find is that the fuses on the switchboard have a rating below the setting of the circuit-breaker, so that the fuses are almost sure to blow before the circuit-breaker will open. This is something that a practical man cannot quite understand. Another inconsistent feature that he is likely to encounter is the use of "open"-type motors in dusty or dirty places; this is especially common in iron works, foundries, etc. When a foundry has a finishing shop, tumbling barrels and emery wheels are employed in cleaning and rough-finishing the castings, and if there is any place on earth where open motors should not be installed it is such a place as this.

The atmosphere of a finishing shop is heavily laden with iron and emery dust, the one a good electrical conductor and the other a most efficient destroyer of the rubbing surfaces in machines; unless the motors in such a shop are frequently "blown out" thoroughly with compressed air, trouble is sure to result. The dust is so heavy that an ordinary hand bellows is practically useless; an air compressor must be used to supply the clearing-out air if the motors are to be kept in anything like proper condition. A pipe-line should be run around past the different motors, and supplied with air from the compressor; a hose connection should be inserted in the pipe-line at each motor for convenience in the use of the cleaning hose, as well as to reduce the length of it. Unless the compressor is equipped with a moisture eliminator, the compressed air will be charged with water; in order to make sure that moist air is not blown into the machines, air should be allowed to blow through the hose for several seconds before turning it on a motor.

In foundries and finishing shops, the heavy dust will cause the carbon brushes on the motors to wear away rapidly; on this account the tension of the brush springs should be carefully adjusted at frequent intervals.

Whoever invented or first suggested mounting motors on ceilings must have never enjoyed the pleasure of keeping them in good condition. Of course, the object in so mounting the machines is to economize in floor space, increasing the area available for work, but in practice this object is seldom realized. The much-valued space which would otherwise be occupied by the ceiling-mounted motors is usually filled with junk, and when an attendant finds it necessary to inspect a machine or make adjustments, etc., he must first remove the odds and ends lying around under it before he can set his ladder.

The "dust-proof" box that encloses a housed ceiling-mounted motor is usually just big enough to contain the machine, thereby preventing proper inspection, adjustments and cleaning. The rods that suspend the box from the ceiling and the braces employed to resist the belt pull or other strains further add to the difficulty of getting at the machine. Moreover, it will generally be found that the box is by no means dust-proof, but rapidly accumulates dust inside; this combines with oil drippings or leakage to form a compound extremely difficult to remove and one which, if left undisturbed, will surely result in spontaneous combustion ultimately.

Oil pans are fitted beneath the journal boxes of motors to catch the leakage, and these must be kept in good condition; if they are allowed to fill, they will overflow, of course, and may cause considerable damage. A syringe will be found very handy to use in keeping the oil level down.

The box around a housed motor is seldom equipped with a lamp socket, so that the motor attendant must carry with him a length of flexible cord, a lamp and socket at one end of it and an attachment plug at the other, in addition to his working tools and appliances. A great convenience in this sort of work is a white pine box about 18 or 20 inches long, 10 inches wide and 4 or 5 inches deep, with ½-inch walls; a handle should be located at the middle of the long side. Such a box can accommodate screwdrivers, pliers, an oil can, fuse plugs, tape, sandpaper and blocks, and clean wiping cloths; and if a few porcelain cleats and screws to fit them are included it will save many a trip back to the storeroom. The use of this box will be found immeasurably better than trying to carry in one's overalls the implements mentioned.

When the boiler room and engine room are located below the sewer level, the blow-off pipes, engine drips, waste pipes, etc., are connected to a receiving tank which is usually located in a pit or tunnel where very little room for inspection or repairs is available. This place is so filled with piping of every description that it is next to impossible to keep the connections in anything like decent condition. Should a leak occur in one of the under pipes, it necessitates the removal of numerous connections before repairs can be made; and all these must be restored, of course, after the repairs are finished.

The receiving tank is usually provided with a pump and pump-governor, supposed to keep the tank free of water automatically. The pump and governor being situated in such an inconvenient place, however, they seldom receive even half-way attention, so that the tunnel is extremely likely to become flooded with water at any time. When this does occur, the engine drips and exhaust drips become practically useless, and the conditions become dangerous, not to mention the great inconvenience of operation. Of course, the pump should be kept well packed and oiled, but it is doubtful if many engineers or assistants would care to risk being half cooked in order to do so.

Why a water main should ever be buried in a concrete floor is another obscure problem. Water mains so situated deteriorate rapidly and sooner or later develop leaks; the repairing of these of course necessitates digging up the floor.

When two or more engines are connected to a common exhaust main, a valve should be inserted in each individual exhaust pipe, preferably right at the cylinder if the engine is of the high-speed automatic type; without such a valve, it will be difficult to pack an idle engine on account of the exhaust steam backing through from the running engines. Under such conditions, it is advisable to put in a blind flange when any inside work is to be done on an engine; this is accomplished by opening the flanged connection in the engine exhaust pipe and slipping a piece of sheet iron and a rubber gasket in between the adjacent flanges. The iron and gasket must be of at least as large diameter as the outside of the flange, and

must have half as many bolt holes as the flange so as to permit closing the joint temporarily with half the total number of bolts. If the flange has more than eight holes, however, only four bolts may be used instead of half the total number, spacing the four as nearly equidistant as possible.

NOTES ON VALVES.

BY CHAS. L. HUBBARD.

Among the requirements of a good valve are sufficient weight of metal to prevent its being bent or sprung out of shape when connected with the piping; valve seats that are easily repaired or renewed; freedom from pockets or projections which may catch dirt or scale, and construction permitting the easy packing of the stem or spindle.

Gate valves offer very little resistance to the flow of steam or liquid passing through them and are generally used in the best class of work. The general construction of this type of valve is shown in Figs. 1 and 2, which represent the "inside" and "outside" patterns of the Chapman valve. In the former the spindle remains stationary, so far as any vertical movement is concerned, and the gate or plug being attached to it by means of a threaded nut rises into the bonnet when the spindle is revolved. With this form of valve it is impossible to tell by its appearance whether it is open or closed unless provided with some special indicating device. With the outside screw, the upper portion of the spindle is threaded and is operated by a revolving nut which is journaled in the yoke and turned by the hand-wheel. The operating screw of this valve is entirely outside the valve body, where it can be inspected and oiled, thus facilitating easy operation, and the spindle rises through the stuffing box without turning, which allows the packing to be kept tight without difficulty. With valves of this type the attendant can tell at a glance whether they are open or closed. For these reasons, outside-screw valves are preferable for high-pressure work and especially so for the larger sizes. In the case of low-pressure heating work, the inside screw is more commonly used. The Chapman gate or plug is made wedge-shaped and presses against ground seats when closed. The seats are made both solid and removable and of various materials for different pressures.

Gate valves of different makes vary chiefly in the smaller details of construction. In the Ludlow valve the plug or gate is made in two parts having their outer faces parallel, as shown in Fig. 3, instead of being wedge-shaped, as shown in Fig. 2. Between these two parts is a wedge with the thicker end at the bottom. When the valve is closed, the plug first descends and loosely closes the opening; then a further movement of the stem brings the two parts of the gate hard against the wedge, which forces the outer surfaces tightly against the seats. In certain forms of the Fairbanks valve the distinctive feature is a metal cage which holds the seat rings in place. With valves of this form the rings can be renewed by simply taking off the bonnet and without removing the valve from the pipe line. A special seat ring of vulcanized asbestos is used in this valve.

In choosing a valve, care should be taken to select one in which the material of the seat or ring is suited to the steam pressure to be carried. Bronze seats are commonly used for pressures over eighty pounds, unless the Babbitt metal or other material employed is especially prepared for higher pressure and is guaranteed by the makers. A gate valve should never be placed in a steam pipe with the spindle pointing down-

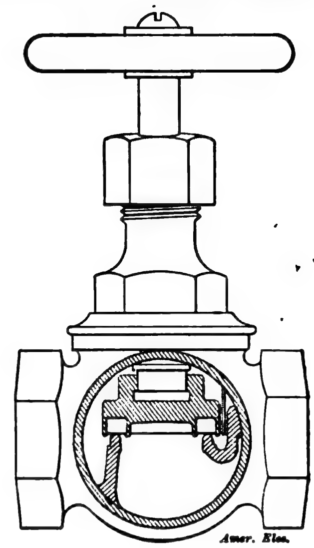

FIG. 5.—GLOBE VALVE.

ward, for when only partly open, the gate projecting from the bottom upward forms a pocket that will hold back the condensation and may thereby be the cause of serious injury to the plant. When placed with the stem extending upward or in a horizontal position, a clear passage is always provided at the bottom of the pipe. Valves are made in different weights and the pressure to be carried should always be stated in ordering them.

By-pass valves should be used in high-pressure work for sizes 8 inches in diameter and over. The two principal disadvantages corrected by the use of by-pass valves in high-pressure mains are, first, when the valve is closed there is an enormous pressure against one side of the gate, which makes it very hard to start; second, as the gate is pressed so tightly against the seat on the side opposite the supply source,

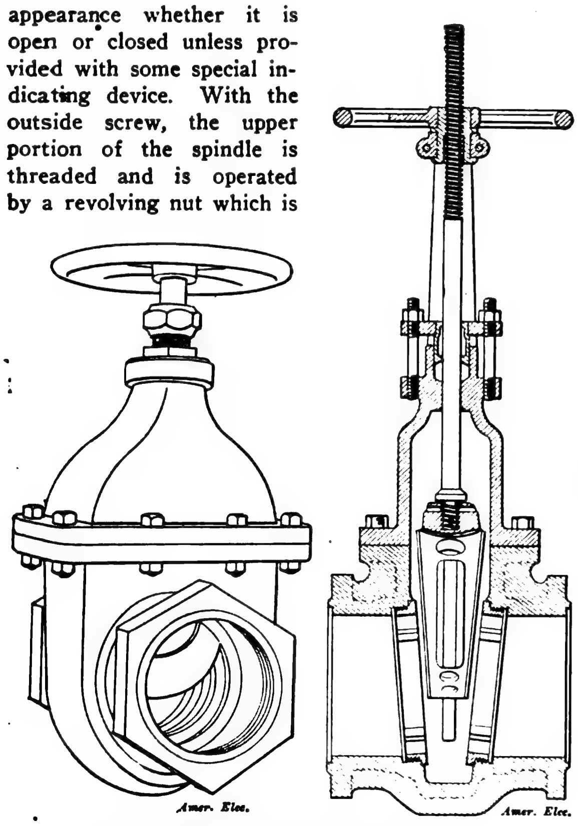

FIG. 1.—CHAPMAN GATE VALVES.—FIG. 2.

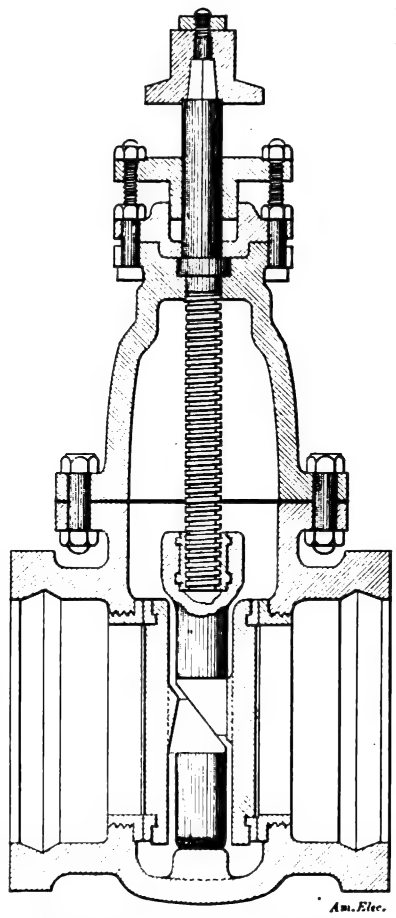

FIG. 3.—LUDLOW GATE VALVE.

FIG. 4.—FAIRBANKS GATE VALVE.

it is apt to score the smooth surfaces of the gate and seat when opened. Moreover, when the main valve is used in the supply pipe to an engine it is desirable to admit steam very slowly when "warming up" the engine, and this is much more easily accom-

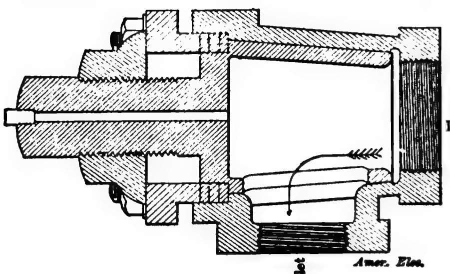

FIG. 6.—SHAW BLOW-OFF VALVE.

plished by means of a small easily-operated by-pass valve than by the use of the main valve.

Globe valves should always be set to close against the pressure, for if placed in the opposite direction they could not be opened if the valve should become detached from the stem, and no indication of the trouble would be given by the action of the stem under these conditions. Globe valves should never be placed in a horizontal steam or dry return pipe with the stem in a vertical position, because the condensation must fill the pipe half full before it can flow through the valve; this will be evident from an inspection of Fig. 5.

The blow-off pipe of a boiler is usually provided with a plug cock, and a gate valve is placed between it and the boiler as a safeguard in case of a leak. Special blow-off cocks and valves are sometimes used in place of the ordinary plug cock and valve. Fig. 6 shows the Shaw blow-off cock. This is made very heavy and so designed that it is difficult for dirt or scale to lodge beneath the seat. The difficulty experienced with the ordinary plug or blow-off cock is its liability to leak unless set down very hard against its seat, in which case it is apt to stick, especially upon "starting" it. To overcome this, certain forms have been designed so that after the cock is closed a further movement of the stem in the same direction forces the plug firmly against its seat by means of a cam located at the top of the plug. A slight movement in the opposite direction releases the cam and allows the plug to turn easily to the open position.

When it is necessary that the flow of steam or water shall always take place in the same direction, check valves are used. There are several forms of this type of valve in use, the most common of which is shown in Fig. 7. The seat in this valve is placed at an angle of about 45 degrees with the direction of the flow. The valve is fitted somewhat loosely where it is fastened to the swinging arm, so that it may properly seat itself. This form is usually preferred in heating work as it offers less resistance to the flow of steam or water and by its construction, offers but little opportunity for scale or sediment to lodge on the seat. When it is desired to reduce the resistance to a minimum, the check may be turned partially on its side, or a special aluminum clapper may be used. Spring checks are especially adapted for use in boiler-feed pipes where the water is supplied by a pump. The clapper being held in place by a light spring, it is prevented from beating against the seat between the strokes of the pump. Check valves are inserted in pipes at all places where it is desired to prevent the pressure in one pipe from "backing" into another, as when several return pipes from a building are brought into a common receiving tank. When used in a return pipe, the check should always be placed below the water line if possible.

It is often necessary to provide steam at different pressures in the same building, as in the case of a combined power and heating plant. In this case, the reduction in pressure is accomplished by passing the steam through a reducing valve. There are many different forms of these valves, the operation of all being based upon the same general principles.

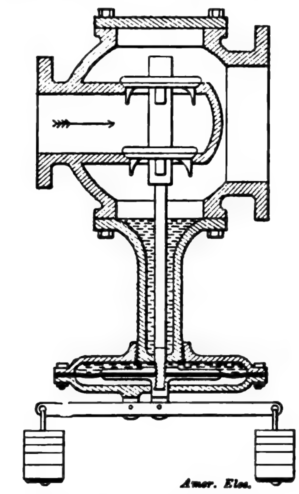

FIG. 8.—RIELY REDUCING VALVE.

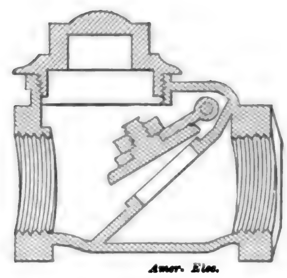

FIG. 7.—CHECK VALVE.

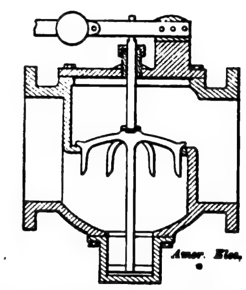

FIG. 10.—BACK PRESSURE VALVE.

In the Kiely valve, shown in Fig. 8, the low-pressure steam acts upon the top of a flexible diaphragm, and the weighted lever, which may be adjusted to give the desired

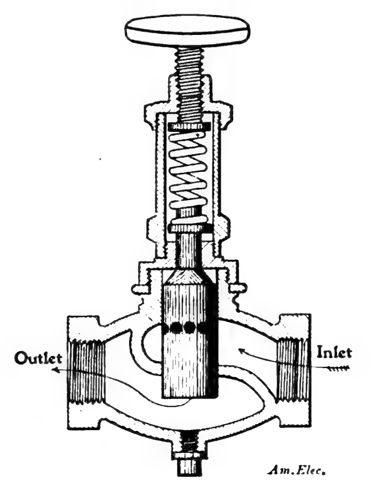

FIG. 9.—WATSON REDUCING VALVE.

reduction in pressure, acts upon the other side. The movement of the diaphragm causes the balanced valve at the upper end of the spindle to open or close, as may be necessary to maintain the desired lower pressure. In the Watson valve, Fig. 9, the reduced pressure acts upon the lower end of a piston valve having an adjustable spring at the top. As the piston simply passes through the inlet chamber its action is not affected by the high-pressure steam surrounding it. There are several good valves in use which embody the same principles, or a combination of the two. Those mentioned are among the simplest and are, therefore, appropriate for purposes of exemplification.

When the reduction in pressure is large, as in the case of a combined power and heating plant, the valve may be one or two sizes smaller than the low-pressure main into which it discharges. For example, a 5-in. valve will supply an 8-in. main, a 4-in. valve a 6-in. main, a 3-in. valve a 5-in. main, a 2½-in. valve a 4-in. main, and so on. For the smaller sizes the difference should not be more than one size. Every reducing valve should be provided with a valved by-pass for cutting out the reducing valve in case of repairs.

A back-pressure valve is a form of relief valve which is placed in the exhaust pipe from an engine or pump to prevent the pressure in the heating system with which it connects from rising above a given point. Its function is opposite to that of the reducing valve, which supplies more steam when the pressure becomes too low. The form shown in Fig. 10 is for a horizontal pipe and consists of a disc closing the port and held in place against the pressure by a weighted lever as shown. The pressure at which it is desired to have the valve open may be adjusted by moving the weight

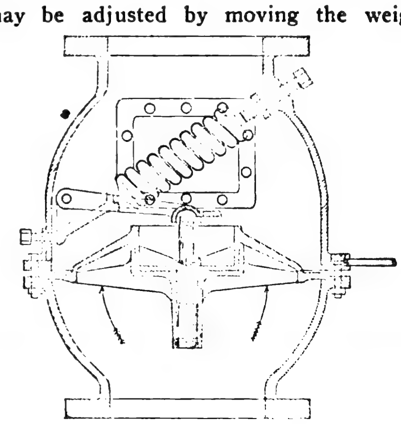

FIG. 11.—FOSTER BACK PRESSURE VALVE.

along the lever. In the Foster valve, a spring is used in place of a weight. This valve has a single disc moving in a vertical direction. The valve stem is in the form of a piston or dashpot which prevents a too sudden movement and makes it more quiet

in its action. The disc is held on its seat against the steam pressure by a lever attached to a spring. When the pressure of the steam on the underside becomes greater than the tension of the spring, the valve lifts and allows the steam to escape. The tension of the spring can be varied by means of an adjusting screw at its upper end.

DISEASES OF ELECTRICAL MACHINERY.

BY F. B. CROCKER AND S. S. WHEELER.

G. Speed too High or too Low.

This is generally a serious matter in either generator or motor, and it is always desirable and often imperative to stop the machine immediately, and make a careful investigation. This trouble may occur with either type of generator, due to Causes 1, 2, 3 or 4; with direct-current motors for Causes 5, 6 and 7; with series-wound, single-phase motors for Cause 7. It does not apply to synchronous or induction motors except when Cause 1 (overload) becomes excessive in which case they stop. (See following Class H.)

SPEED TOO LOW.

Cause 1.—Overload.

Symptom and *Remedy*.—See "Sparking," Cause 1, and "Heating of Armature."

Cause 2.—Short-circuit or ground in armature.

Symptom and *Remedy* the same as for "Heating of Armature," Causes 2 and 7.

Cause 3.—Armature strikes pole pieces.

Symptom and *Remedy* the same as for "Noisy Operation" Cause 2.

Cause 4.—Shaft does not revolve freely in the bearings.

Symptom and *Remedy*.—See "Heating of Bearings," all causes.

SPEED HIGH OR LOW.

Cause 5.—Field magnetism weak.

This has the effect, on a constant-potential circuit, of making a series or shunt motor run too fast if lightly loaded, or too slowly if heavily loaded, or even run backwards if the field magnet is not excited at all, as, for example, when the shunt field circuit is broken. It makes a generator fail to "build up" or excite its field, or fail to give the proper voltage.

Symptom and *Remedy* the same as for "Sparking," Cause 8. (See the following Cause; also "Dynamo Fails to Generate.")

Cause 6.—Too high or too low voltage on the circuit.

Symptom.—This causes a direct-current motor to run too fast or too slowly, respectively. It would have a similar effect upon a series or shunt-wound alternating-current motor. It would not affect the speed of a synchronous motor until the voltage became so high as to injure it or so low that it stopped. When the voltage of a generator or motor is too high it is likely to give the effects of overload (Cause 1). It can be proved by measuring the voltage of the circuit.

Remedy.—The central station or generating plant should be notified that the voltage or current is not right

Cause 7.—Motor too lightly loaded.

Symptom.—A series-wound motor on a direct or alternating constant potential circuit runs too fast and may speed up to the bursting point if the load is very much reduced, or removed entirely (by the breaking of the belt, for example).

Remedy.—Care should be exercised in using a series motor on a constant-potential circuit, except where the load is a fan, pump, or other machine that is *positively* connected or geared to the motor, so that there is no danger of its being taken off. A shunt motor should be used if the load is likely to be thrown off.

H. Motor Stops or Fails to Start.

This is an extreme case of the preceding class ("Speed Too High or Too Low"), but is separated because it is more definite and permits of quicker diagnosis and treatment. This trouble may occur in direct or alternating-current motors, but does not apply to generators, because any trouble in setting them in motion is generally outside of the machine itself, but might be due to Causes 1 and 2, below.

Cause 1.—Great overload. (See "Sparking," Cause 1.)—A moderate overload usually causes a motor (except the synchronous type) to run slowly, but an extreme overload will stop it entirely or "stall" it.

Symptom.—On a constant-potential circuit the current is excessive, and safety-fuse blows or circuit breaker opens. In their absence or failure the armature is likely to be burned out.

Remedy.—Open the switch instantly, reduce or take off the load, replace the fuse or circuit breaker, and turn on current again just long enough to see if trouble still exists; if so, take off more load.

Cause 2.—Very excessive friction due to shaft, bearings, or other parts being jammed, or armature touching pole pieces.

Symptom and *Remedy*.—See "Sparking," Cause 1; "Heating of Bearings," and "Noisy Operation."

Cause 3.—Circuit open, due to (*a*) safety-fuse blown or circuit breaker open, (*b*) wire broken or slipped out of connections, (*c*) brushes not in contact with commutator or collector rings, (*d*) switch open, (*e*) circuit supplying motor open, (*f*) failure at generating station.

Symptom.—Distinguished from Causes 1 and 2 by the fact that if the load is taken off the motor still refuses to start, and yet armature turns freely.

On a constant-potential circuit the field circuit alone of a shunt motor may be open, in which case the pole pieces are not magnetic when tested with a piece of iron, and there is a dangerously heavy current in the armature; if the armature circuit is at fault there is no spark when the brushes are lifted, and if both are without current there is no spark when the main switch is opened. When there is no field magnetism or even if it is weak, a motor is apt to be burned out if its armature is connected to the circuit, unless protected by fuses or a circuit breaker.

Remedy.—Open the main switch or circuit breaker immediately, and examine fuses, circuit breaker, wires, brushes, switch and circuit generally, for break or fault. If none can be found, close switch again for a moment, as the trouble may have been due to a temporary stoppage of the current at the station or on the line. If motor still seems dead, test separately armature field-coils and other parts of circuit for continuity with a magneto or a cell of battery and an electric bell to locate any break that may exist.

One of the simplest ways to find whether the circuit has current on it and to locate any break, is to test with an incandescent lamp, or several in series for higher voltages.

The remedy for a break in a direct-current armature winding was given under "Sparking," Cause 6. Similar expedients are applicable to alternating-current machines, the coil in which the break has been located being cut out by connecting together the adjacent coils. This may be done whether the break is in the armature or field coils. Furthermore, alternating-current machines are free from the danger of internal short circuiting which may occur in multiple-circuit direct-current armatures when a field coil is cut out (see "Sparking," Cause 9), because the armature winding is usually single circuit.

A single-phase motor is stopped by a break in its circuit, but a two or three-phase motor will continue to run as a single-phase motor if the circuit of one phase is broken. It is, however, more easily stopped, and is incapable of starting itself.

Cause 4.—Wrong connection or complete short-circuit of field, armature, switch, etc.

Symptom.—Distinguished from Causes 1 and 2 in the same way as Cause 3, and differs from Cause 3 in the evidence of strong current in the motor.

The possible complications of wrong connections are so great that no exact rules can be given. Carefully examine and make sure of the correctness of all connections. This trouble is usually inexcusable, since only a competent person should ever set up a motor or change its connections.

In the three-wire (220-volt or 440-volt direct-current) system several peculiar conditions may exist, as follows:

(*a*) The generator or generators on one side of the system may become reversed, so that both of the outside wires are positive or both negative. In that case a motor fed in the ordinary way from the two outside conductors will get no current, but lamps connected between the middle or "neutral" wire and either of the outside wires will burn apparently the same as usual.

(*b*) If one of the outside conductors is opened by the blowing of a fuse, an accidental break, or other cause, then a motor (220 volt) beyond the break can get some current at 110 volts through any lamps that may be on the same side of the break as itself, and on the same side of the system as the conductor that is open. These lamps will light up when the motor is connected, but the motor will have little or no power unless the number of lamps is large.

(*c*) If the neutral or middle wire is open, a motor connected with the outside wires will run as usual; but lamps on one side of

the system will burn more brightly than those on the other side, unless the two sides are perfectly balanced.

(*d*) If one of the outside wires becomes accidentally grounded, a 110-volt generator, motor or other apparatus also grounded and connected to the other outside wire, will receive 220 volts, which will be likely to burn it out.

I. Voltage of Generator too High or too Low.

This is a common difficulty that may arise with any machine. The particular case of the self-exciting direct-current generator is treated by itself under the following heading, "Dynamo Fails to Generate," because it is a perfectly definite condition like "Motor Stops or Fails to Start." The various circumstances that interfere with the generation of the proper voltage are here stated.

Cause 1.—Speed too high or too low.

Symptom and *Remedy*.—See "Speed Too High or Too Low," Class G, already discussed.

Cause 2.—Field magnetism strong or weak.

Symptom and *Remedy*.—See "Sparking," Cause 8, also "Dynamo Fails to Generate," various causes.

Cause 3.—Brushes not in proper position.

Symptom and *Remedy*.—See "Sparking," Cause 2, also "Dynamo Fails to Generate," Cause 6.

Cause 4.—Generator overloaded.

Symptom and *Remedy*.—See "Sparking," Cause 1, also "Speed Too High or Too Low."

Cause 5.—Short-circuited or reversed armature coils.

Symptom and *Remedy*.—See "Sparking," Cause 5.

Cause 6.—Open-circuited, short-circuited or reversed field coils.

Symptom and *Remedy*.—A break in the field circuit of a generator prevents it from producing any voltage except the small amount due to residual magnetism. A short-circuited field coil produces a corresponding reduction in ampere-turns, provided the field current remains constant. This would be true in the series coil of a series or compound-wound machine. In shunt-wound or separately excited field coils, however, the current would tend to increase in proportion to the decrease in the effective coils, in which case the field strength and voltage would remain the same. This condition is nevertheless bad, because the active field coils carry excessive current. (See "Heating of Field Magnets, Cause 1.") In machines with many field coils (for example, eight or more, including practically all alternating-current and large direct-current types) the cutting out of one, on account of an open or short-circuit in it, would not involve a rise in current likely to do harm.

One reversed coil would have the same effect as the loss of two coils, the field resistance and current being unchanged. Hence the current would have to be considerably increased by means of the field regulator to obtain the proper voltage, this increase being twice as great as for one short-circuited coil. A short-circuited or reversed field coil is very objectionable in a multipolar, multiple-circuit direct-current machine, as already explained. (See "Sparking," Cause 8, and "Dynamo Fails to Generate," Causes 2, 3, 4 and 5.)

Cause 7.—Lagging current in alternator. A direct-current or alternating-current generator, unless compound or composite-wound, tends to fall in voltage with increase in load (Cause 1) on account of armature resistance, inductance and reaction. This is usually overcome by raising the field current by means of a rheostat. In an alternating-current generator a given armature current produces much greater reaction and weakening of the field when it lags, so that the voltage fall and regulation required are correspondingly large.

REPAIR SHOP NOTES.

BY O. B. EVE.

Having noticed occasional articles in the American Electrician on methods of repairing and testing armatures and field magnet coils, it occurred to me that the following simple devices and methods might be of interest to some of the readers of this paper:

For testing out crosses in a commutator or an armature winding, I have found it a good plan to pass current through the armature by way of the regular brushes and to test each adjacent pair of commutator bars with a telephone receiver and a pair of contacts mounted on a block, as shown by Fig. 1. The brushes should be set exactly as they are for running, and the current controlled by some such means as a water or wire rheostat; ten amperes will usually suffice, and the current may be either direct or alternating. The armature may be mounted on blocks or in its bearings. If everything is clear, a distinct hum will be heard in the telephone when the contacts are pressed against two commutator segments; a cross between adjacent leads or commutator bars will cut out the humming entirely, while a cross within a coil will reduce it very perceptibly.

For testing out a ground, the terminals of the telephone receiver are connected to the two brushes of the machine and one of the brushes is connected to the frame (or the shaft, if the armature is taken out of the frame). The armature is then revolved slowly by hand, with current passing through from brush to brush; when the segment connected to the coil that is grounded

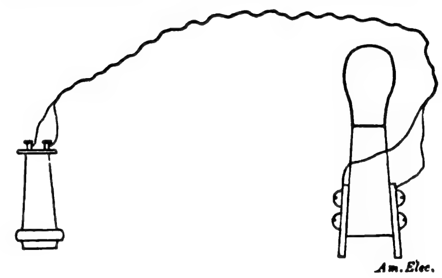

FIG. 1.

comes in contact with the ungrounded brush, the telephone will be short-circuited and the humming will, of course, cease.

These tests are reliable and have the advantage that a voltmeter is not required; the use of a voltmeter involves the difficulty of watching the instrument and the test contacts simultaneously, not to mention the expense of buying the voltmeter if you happen not to have one.

The arrangement shown in Fig 2 will be found very convenient and efficient for testing out short-circuits in field-magnet coils. It comprises a frame of laminated steel (transformer "iron"), the upper horizontal leg of which is removable. The core is 6 ins. x 8 ins. in cross-section and the horizontal pieces of it are 16 ins. long, leaving a clear space between the uprights of 4 inches. The bottom piece is held between two pieces of hardwood which are bolted together beyond the ends of the iron. The

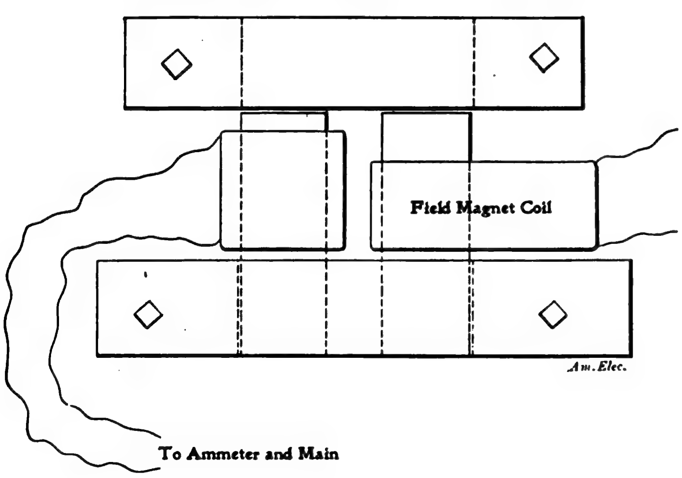

FIG. 2.

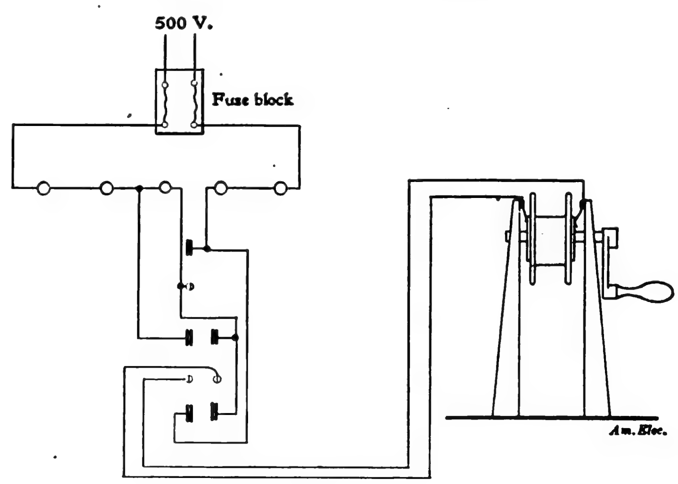

FIG. 3.

upper member is similarly mounted, and in this case the bolts near the ends of the wood cheeks serve as handles by which to lift the leg. A coil consisting of 60 turns of No. 5 magnet wire is slipped over one of the uprights and the field magnet coil that is to be tested is slipped over the other, as indicated roughly in the sketch. The magnetizing coil is connected to a 110-volt alternating-current in series with an ammeter,

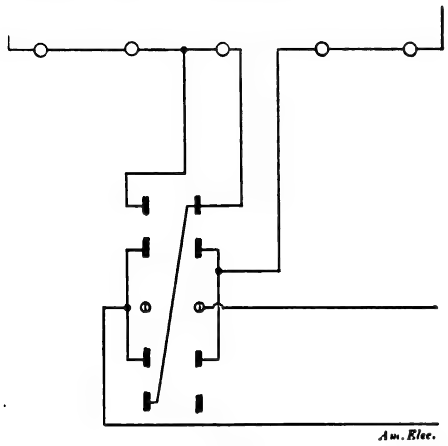

FIG. 4.

and if the field-magnet coil is sound, the ammeter will not show any more current with the field coil on the core than without it; any cross or short-circuit in the tested coil, however, will increase the ammeter indication, and if only a few turns are short-circuited the coil will immediately become hot.

Fig. 3 indicates a convenient method of taking either 100 or 500 volts from a 500-volt circuit for testing purposes. A double-pole, double-throw switch and a single-pole, single-throw switch are used to connect the testing leads either in series with a group of five (which are in series on the 500-volt circuit) or across the terminals of one of the lamps; the former connection, of course, gives 500 volts and the latter 100. The switches might advantageously be so mounted on a board that the handles would interfere with each other if not thrown properly, or a double-break switch might be used, as in Fig. 4; either plan would avoid any liability of an attempt to put the test leads in series with the lamps while the single-pole switch is closed.

The test leads are carried from the switch to two brushes on a reel frame which bear against slip rings on the sides of a reel, as indicated in Fig. 3; the inner ends of a duplex flexible cord are connected to the slip rings and the outer ends are carried to the work. The use of the reel avoids the nuisance of having a long length of cord lying about the floor when the work is near by.

In winding field magnet coils, two rollers located near the winding frame and arranged as shown in Fig. 5 will be found of much help in counteracting the tendency of the wire to bow outward away from the layer beneath it. In taping a coil, it will be found of advantage to provide a wooden

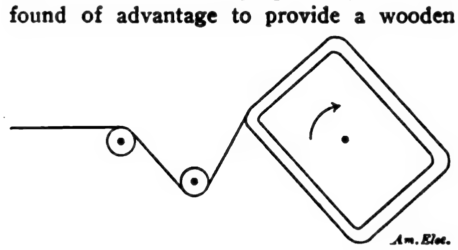

FIG. 5.

turn-table about 18 ins. in diameter surmounted by four blocks about 4 ins. square and 6 ins. long; the coil is laid on the blocks, and these are moved out of the way of the tape, one at a time, as the taping progresses.

EXTRACTING OIL FROM EXHAUST.

BY W. A. DOW.

In small steam plants where exhaust steam is used for heating purposes, little consideration is paid to the consumption of water or coal and a record of the maintenance or running expense is seldom kept. The plant is usually run more by guess than by actual figures. About twelve years ago the writer took charge of a plant, consisting of a slide-valve engine, one return tubular boiler, a boiler feed pump, a heater and receiving tank for the heating returns, and a small trap. The building was heated in winter by exhaust and live steam. But little thought was given to the economy and instead of returning the water of condensation to the boiler, it was trapped from the receiving tank to the sewer. My predecessor informed me that his reason for doing away with the returns was that he did not feel that it was safe to return it to the boiler on account of the oil in the exhaust steam, and the company would not install an oil extractor. I thought this a very poor excuse and decided to first get rid of the oil in the returns and then return it to the boiler. The apparatus I used is shown in the accompanying sketch. The exhaust steam enters the heater, *S'*, through the pipe, *O*, and passes out through the pipe, *S*, to the heating system, the returns entering the tank, *N*, through the pipe, RR_1. When the condensation accumulates and partly fills the tank, it runs out by gravity into barrel No. 3, passing out at the bottom and entering barrel No. 2, passing out of No. 2 at the bottom and entering barrel No. 1 at the top. It will be seen that a float is placed in the first barrel and hinged to the side of it at *F*. A bracket was made fast to the inside of the barrel that acted as a guide to the valve steam, *U*, shown at *B*. A joint is placed in the stem at *T* so that the stem below the bracket can move in a straight line when the float is raised or lowered by the action of the water in the barrel. The thread on a globe valve was filed off, so as to allow the stem free movement in the bonnet of the valve; this

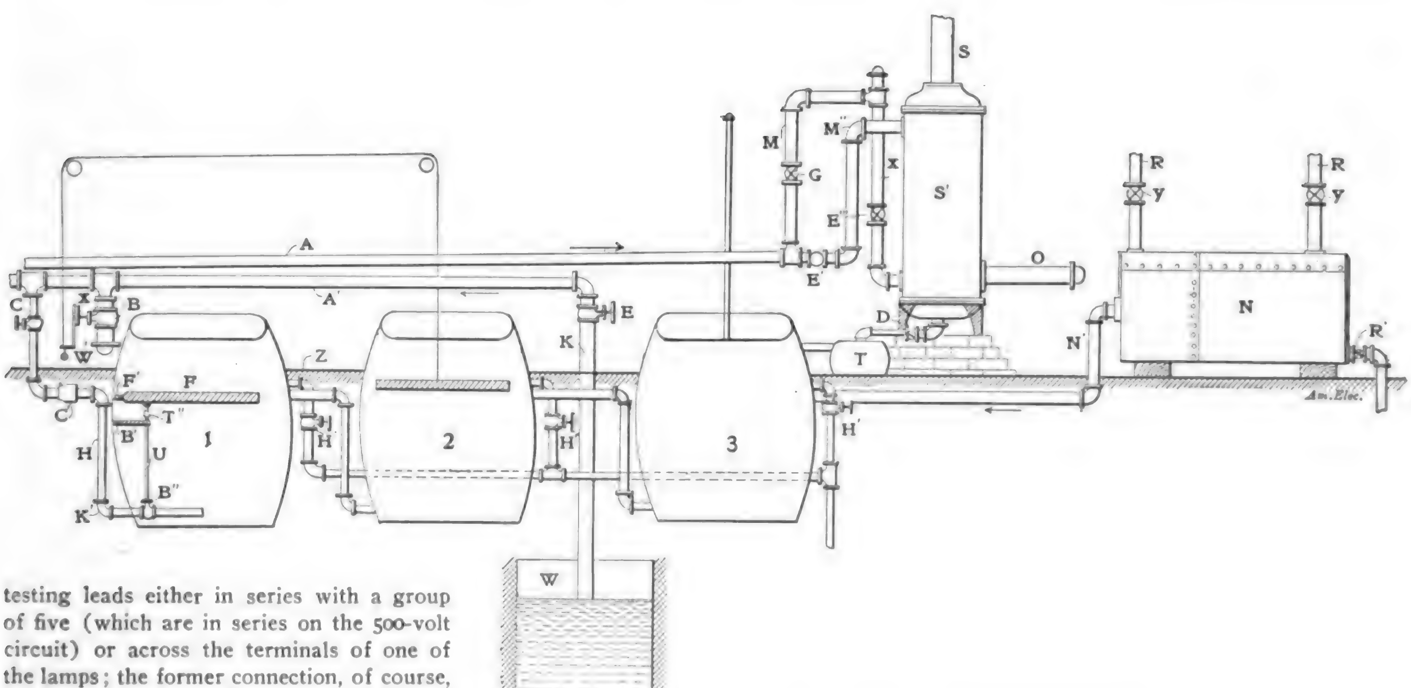

FIG. 1.—EXTRACTING OIL FROM EXHAUST STEAM.

acted as a check valve and is shown at *B"*. The water enters the pipe under the valve and is discharged from the top. A check valve was placed in the suction pipe, *H*, at *c*, to prevent the water entering the barrel

when the city water was used for boiler feed. Water was taken from the well at times, but we did not get good results with this on account of the scale-forming property in it. The city water connection is shown at *B* and the floor line at *Z*. Pipes are connected just above the inlet to the barrels, and are also connected to a common blow-down or drain, as shown at *H'*; as fast as the oil accumulated on top of the water in the barrels it was blown off through this pipe. This kept the water in barrel No. 1 free from oil and perfectly safe to be returned to the boiler.

It is a well-known fact that where heating returns are returned to the boiler very little new water is added to that which is in circulation. It will be seen by tracing the piping that provision is made for this also in order to have the pump draw from the barrels. The city water must be shut off to relieve the check valve, *c'*, of the 40 pounds pressure caused by the tendency of the water to keep it closed. I overcame this obstacle by placing a float in barrel No. 2 and connecting a cord to it, which passed over two pulleys to a lever made fast to the stop valve in the city water main at *X*.

When the water accumulates in the barrels, as before explained, the float moves upward, allowing the weight, *W*, to move downward and close the valve, thus shutting off the water from the city supply. This relieved the check valve, *c*, of the weight on top of it and allowed it to open, and the atmospheric pressure forcing the the pump forming a vacuum on one side water out of the barrels into the pump cylinder.

In case the city water was not needed for any length of time to keep up the supply, the cord was disconnected from the lever and the valve, *X*, closed. It will be seen by the sketch that in a steam plant where all of the water is taken from a well or river that no float will be needed in barrel No. 2. But in any case where the water comes to the pump under pressure, a float or some other arrangement must be used to shut it off while the pump draws the water from the barrels.

The trap was placed between the heater and the barrel, as shown at *T*, and all condensation that accumulated in the bottom of the heater was also discharged into barrel No. 3. It will be seen that the water comes to the pump warm and is forced through pipe *A* to the heater at the top, passing through a coil and discharging at the bottom through the pipe *X* to the boiler.

The change resulted in a great saving in the amount of coal used thereafter and reduced the work of the fireman, for under the old conditions of the plant, where cold water was forced through the heater, it was impossible to keep up the steam pressure at times even by forcing the boiler. The pipe, *M*, is a by-pass, and in case the heater is out of order water is forced to the boiler by opening the valve, *G*, and closing valves *E"* and *E'*. The exhaust pipe is connected in like manner, but is not shown in the sketch. This change pleased the superintendent so well that he raised my salary.

Letters on Practical Subjects

Communications intended for publication in this department must be received at this office not later than the 15th of the month prior to the date of publication.

Mr. Lyons' Motor Trouble.

Referring to Mr. A. C. Lyons' trouble with a three-phase induction motor, which was described in the May number, I should think the trouble was in the compensator; probably in the joint where the taps from the mains connect to the movable arm of the oil switch, or to one finger not making contact. Humming would indicate that the motor was only receiving two instead of three phases. A. C. Towne.

Montreal, Can.

If every electrical part and all connections were in correct condition in the induction motor of Mr. A. C. Lyons, as they appeared to be, the trouble was loose caps of bearings. Had he tightened these he would have seen his motor running. When the caps are not screwed hard down when current is thrown on the stator of an induction motor, the stator draws up the rotor and holds it fast against the upper teeth. If Mr. Lyons wishes to try the experiment he has only to loosen the caps of the bearings of a good induction motor that is running in good order.

M. L. Schiaffino.

Guadalajara, Mexico.

Referring to the trouble Mr. A. C. Lyons had with an induction motor not starting, I would suggest a possible explanation of the trouble. At least I have seen three-phase motors act the same way, and their trouble was due to this cause. When current began to flow in the primary, the rotor was pulled over against the stator laminations, there being a very strong magnetic pull between the two. The reason for this might be a poorly centered rotor, so that the air-gap is not uniform, or the laminations may be loose on either stator or the rotor, or both. These would be drawn together when current was flowing and might spring back (probably would) when the current ceased; so that it would not be apparent on ordinary inspection of the motor when not excited. The rotor bearing must be very rigidly fixed relative to the field.

Schenectady, N. Y. Robt. E. Noyes.

Mr. Turner's Telephone Circuit.

I offer the enclosed diagram (Fig. 1) as a solution of Mr. Turner's problem in telephone signalling circuits published in this department of the May number. The signalling apparatus and polarized bells at each station are connected up separately

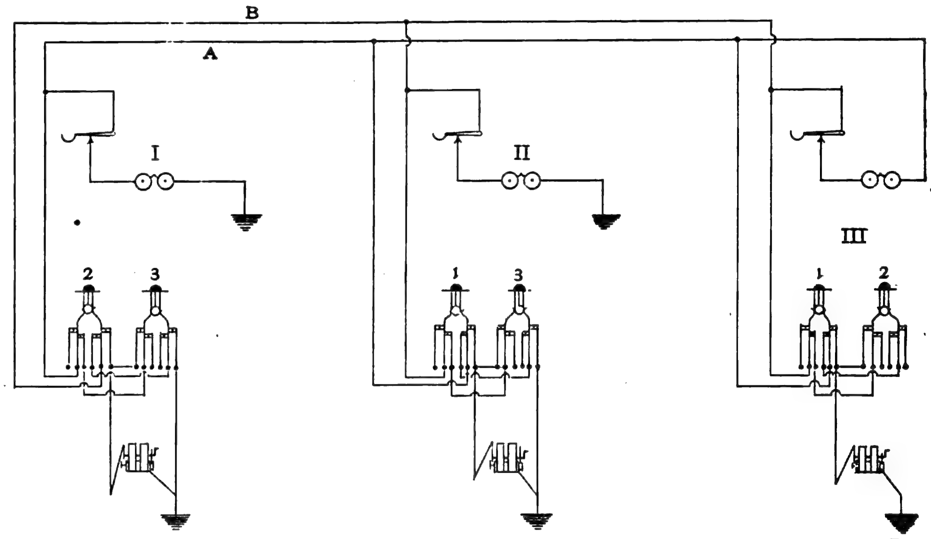

FIG. 1.—MR. BETHEL'S SOLUTION.

from the other apparatus, which is bridged across the line in the usual fashion and is therefore not shown in the diagram. My idea is to use standard push-button keys for signalling, the connections being clearly shown in the sketch. Station *I* has its bell connected between line-wire *A* and the ground; the bell at Station *II* is connected between line-wire *B* and the ground, while the one at Station *III* is bridged across the line as usual. Depressing push-button *2* at Station *I* puts the generator at that station between line-wire *B* and the ground, so that the generator current affects only the bell at Station *II*. Push-button *3* puts the generator across the line, so that it rings the bell at Station *III*. The connections at the other stations are correspondingly ar-

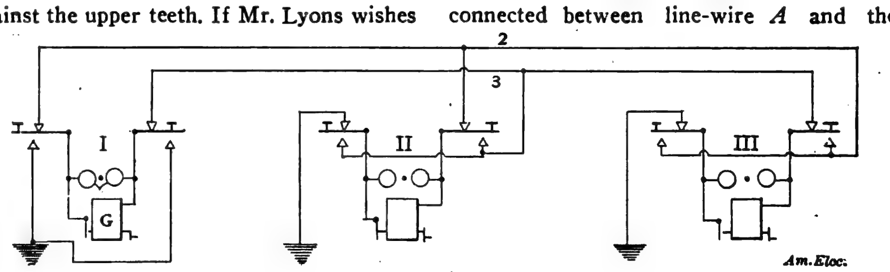

FIG. 2.—MR. BONE'S SOLUTION.

ranged; the button having a given number connects the generator to the bell at the station of the same number.

Washington, D. C. N. P. BETHEL.

The accompanying diagram (Fig. 2) is offered as a solution of Mr. Turner's problem. The talking circuits are the same at all stations and are bridged on the line in the usual manner. The ringing circuits are independent of the hook switches, and the two double-contact (two-way) push-buttons or ringing keys are used at each station. Double-throw, single-pole switches could be used, but trouble might be caused by leaving them in the wrong positions. The keys at each station connect the ringing circuit of that station with the ringing circuit of the stations of corresponding numbers. The ringing circuit at Station *I* is normally bridged across the line by the selective keys; that at Station *II* is normally connected between line-wire *2* and the ground, while that at Station *III* is normally connected between wire *3* and the ground. Consequently, any generator connected across the line will ring the bell at Station *I*, one connected between wire *2* and the ground will ring the bell at Station *II*, and one connected between wire *3* and the ground will ring the bell at Station *III*. If the generator at Station *I* be operated while it is across the line it will probably ring the bells at Stations *II* and *III* as well as that at Station *I*, because those two are in series across the line through their ground connections. If any receiver is off the hook when a signal is given, all the bells will ring, because the line-wires are then bridged by the talking circuit. If both keys are depressed simultaneously at any station, the signalling apparatus at that station will be short-circuited. Any station could probably call the other two simultaneously by ringing without depressing either key; but a button could be provided for disconnecting the home bell, and the other two could then be rung strongly in series.

Reading, Mich. FRANK W. BONE.

The accompanying diagram (Fig. 3) is one solution of Mr. Turner's problem. The talking apparatus at each station is bridged across the line in the usual manner. The ringing apparatus is separated from the hook switches and connected as shown in the diagram: The generator at each station is connected by means of a two-way, single-pole switch to the ringing circuit of either one or the other of the two stations; these switches are to be left open when not signalling.

Colton, Cal. L. P. BRODE.

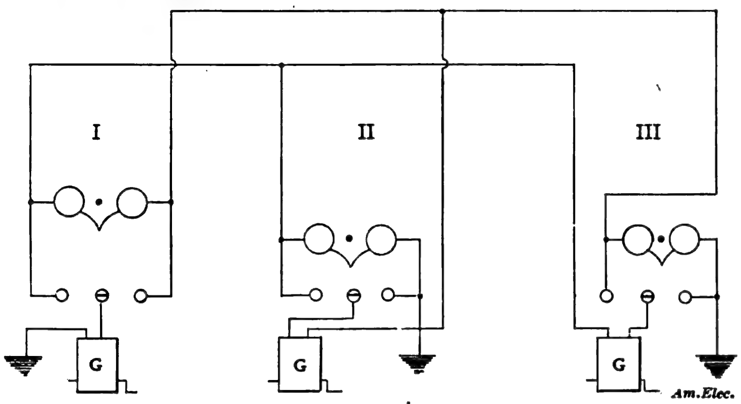

FIG. 3.—MR. BRODE'S SOLUTION.

The simplest solution of Mr. Turner's problem is probably that shown by the enclosed diagram (Fig. 4). At Stations *I* and *II* two double-contact push-buttons are used to select the station to be called. The talking circuit at each of these stations is bridged across the line normally, but one lead passes through the left-hand push-button. The ringing circuit is divorced from the remainder of the set, excepting the hook switch. By tracing the circuits it will be found that the ringing circuit at Station *I* is normally connected between line-wire *1* and the ground; that at Station *II* is normally connected between wire *2* and the ground, while that at Station *III* is divided normally, the bell being bridged across the line through the hook switch as usual and the generator being grounded at one terminal and connected to a two-way switch, *S*, at the other; this switch connects it to either one or the other of the line-wires, but never to both simultaneously. Depressing button *ii* at Station *I* puts the ringing circuit of that station between the line-wire *2* and the ground, so that the generator can ring the bell at Station *II;* depressing button *i* at Station *II* puts that ringing circuit between wire *1* and the ground, ready to ring the bell at Station *I;* depressing the button *iii* at either Station *I* or *II* puts the generator at that station across the line, ready to ring the bell at Station *III*. The switch at Station *III* is normally open, as shown; turning it to button *i* puts the generator in parallel with the bell at Station *I*, and turning it to button *ii* puts the generator in parallel with the bell at Station *II*. If desired, an auxiliary bell could, of course, be connected in parallel with the generator at Station III so as to provide an indication of the performance of the generator; as the circuits are shown, no ring is heard at that station when one of the others is called up. The object in separating the generator from the receiving bell and using a different switching device is to avoid having the generator normally across the line, in which relation it would ring both of the other bells simultaneously if the handle were turned without throwing the selective switch.

Brooklyn, N. Y. GEO. W. MALCOLM.

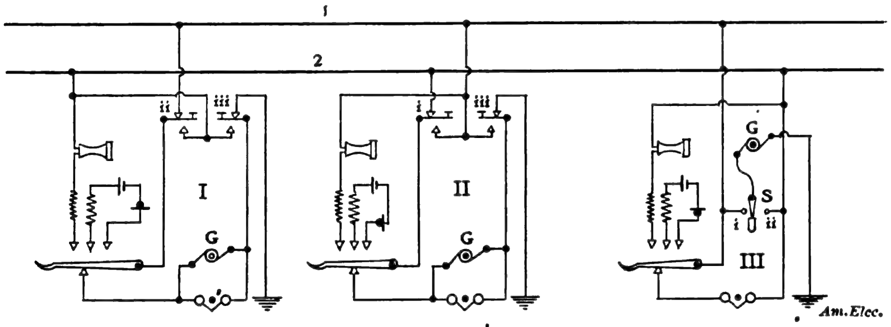

FIG. 4.—MR. MALCOLM'S SOLUTION.

The accompanying diagram (Fig. 5) is submitted as a solution of Mr. Turner's problem published in the May issue. Three-point button switches are used at each station for selective ringing, but knife-blade switches could be used if desired. To call Station *B* from Station *A*, the switch *R* is thrown to the right and the generator

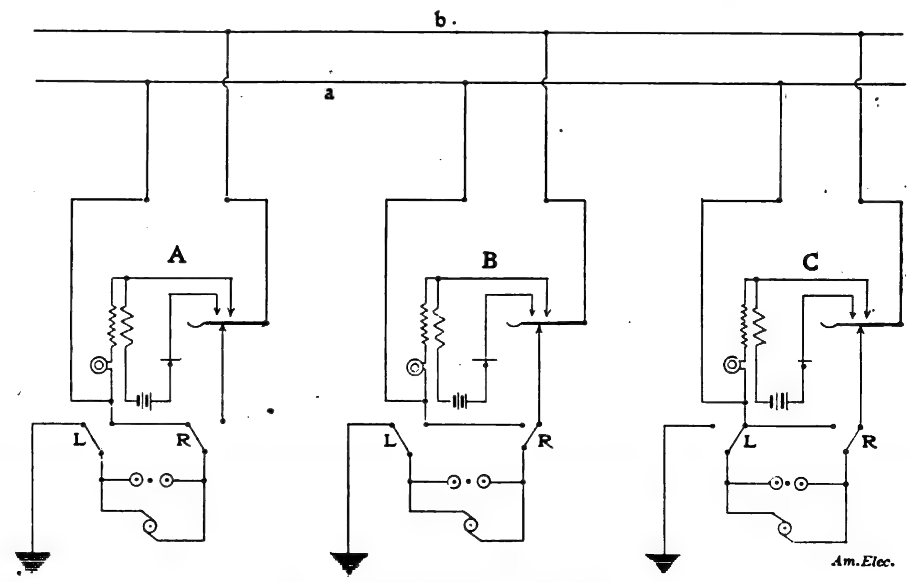

FIG. 5.—MR. SHADBOLT'S SOLUTION.

operated; to call Station *C*, both switches are thrown to the right. At Station *B*, to call Station *A*, the switch *R* is thrown to the left; to call Station *C*, the switch *L* is thrown to the right. At Station *C*, to call *A*, the switches are both thrown to the left, and to call *B*, the switch *L* alone is thrown to the left. All of the switches must normally set as shown in the diagram.

Osage, Minn. W. H. Shadbolt.

Mr. Lincoln's Storage Battery Connections.

The arrangement shown by the accompanying sketch (Fig. 1) fulfills the requirements of Mr. Lincoln's problem published in the May number. The double-pole, double-throw switch *C* puts the whole equipment on either of the supply circuits, *A* or *B*, or cuts it off both for charging the small cells by means of the large ones. With this switch closed in either direction, the cells *P* may be charged through the regulating resistance *R* from one of the supply circuits by throwing the switches *D* and *E* downward, and with *D* closed downward and *E* closed upward, all of the batteries are connected in series to one of the supply circuits. To charge the cells *P* from the cells *X*, *Y* and *Z*, the switch *C* is opened and the other two closed upward. The switches *G* and *H* determine which of the cells *X*, *Y*, *Z* are active.

Washington, D. C. N. P. Bethel.

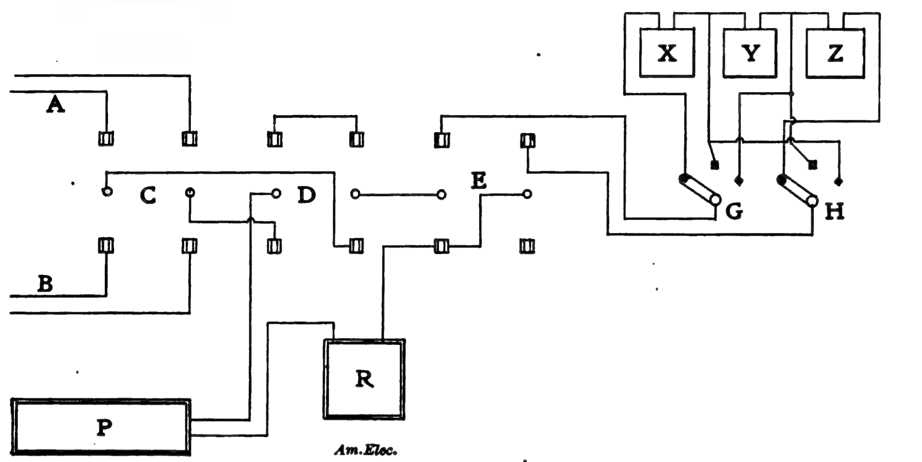

FIG. 1.—MR. BETHEL'S SOLUTION.

Enclosed is a diagram (Fig. 2) which meets the conditions of Mr. Lincoln's problem. With the double-throw switch *D* thrown downward, the switch *C* connects the equipment to either supply circuit, *A* or *B*. Under these conditions, the switches *E*, *F*, *G* determine whether the portable cells *P* shall be put in circuit alone or in series with one or more of the large cells *X*, *Y*, *Z*. By closing the switch *D* upward, the portable cells may be charged by the large cells.

Newark, N. J. F. S. Brewer.

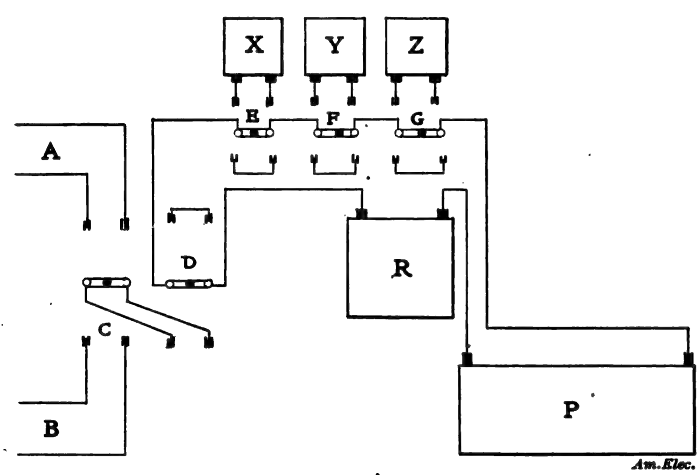

FIG. 2.—MR. BREWER'S SOLUTION.

I offer the enclosed sketch (Fig. 3) as a solution of Mr. Lincoln's problem in battery connections. The double-throw, single-pole switches *E*, *F*, *G*, determine which of the cells *X*, *Y*, *Z*, are actively in circuit; the switch *D* connects this group of cells *X* to the portable cells for charging the latter or to the main switch *C* in series with the portable cells, for charging both of the batteries from one of the supply circuits. The double-pole, double-throw switch *C* connects the equipment to one or the other of the supply circuits, *A* or *B*.

Colton, Cal. L. P. Brode.

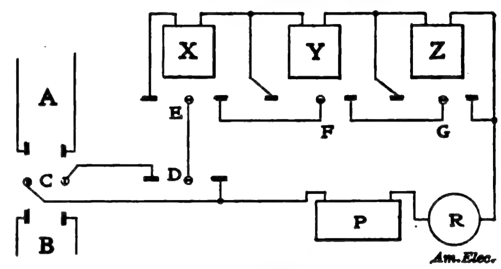

FIG. 3.—MR. BRODE'S SOLUTION.

For solving Mr. Lincoln's problem in storage battery connections I would suggest using one double-pole, double-throw and four single-pole, double-throw switches connected as shown by the enclosed sketch (Fig. 4). The double-pole switch *1* connects the entire outfit to either of the supply circuits or disconnects it from both; the switches *2*, *3*, *4* vary the number of large cells in circuit with the portable battery, and the switch *5* puts the two sets of batteries to the switch *1* in series or cuts them off and connects them together for charging the portable cells from the large ones. If it should be desired to charge the

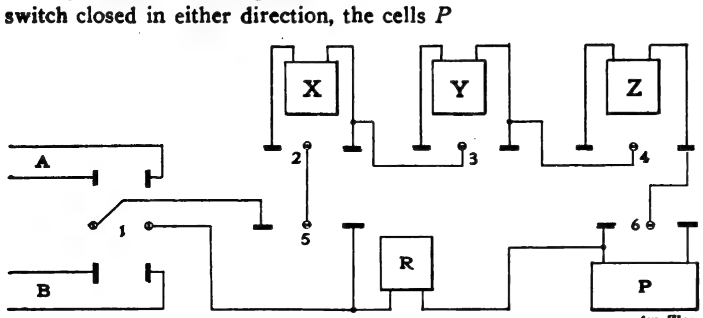

FIG. 4.—MR. FISKE'S SOLUTION.

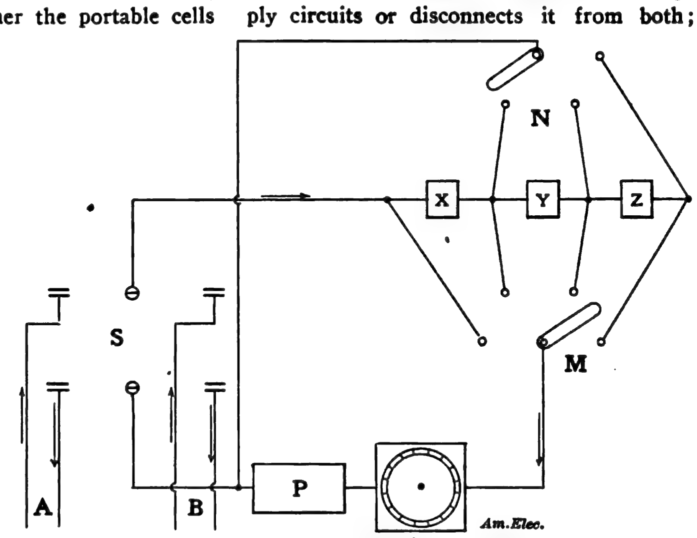

FIG. 5.—MR. JOHNSON'S SOLUTION.

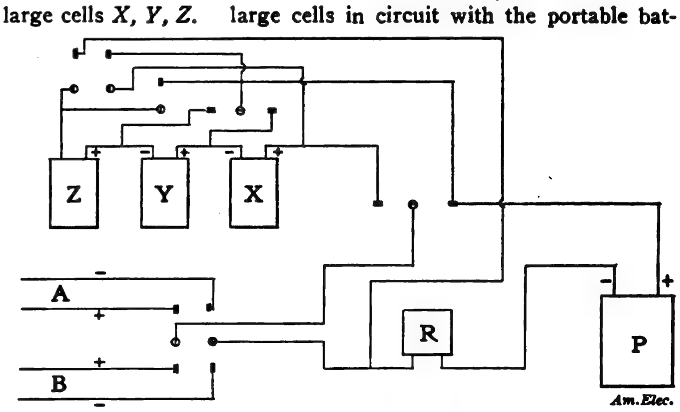

FIG. 6.—MR. LINCOLN'S SOLUTION.

large cells from one of the supply circuits separately from the portable cells, a single-pole, double-throw switch could be connected, as shown at *6*, but this is unnecessary for the fulfillment of the requirements stated in the problem.

Kingston, R. I. HERBERT A. FISKE.

I suggest the accompanying diagram as

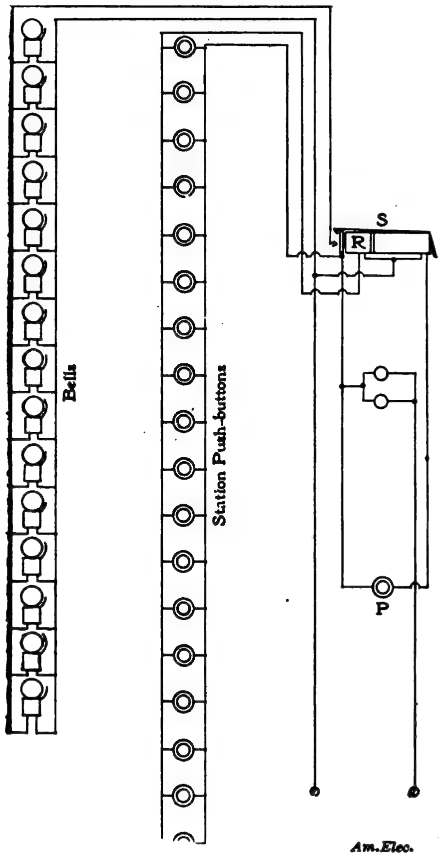

FIG. 1.—MR. BETHEL'S SOLUTION.

a solution of Mr. Lincoln's problem in battery connections. There are four single-pole, double-throw switches and one double-pole, double-throw switch; the latter (*1*) is used to

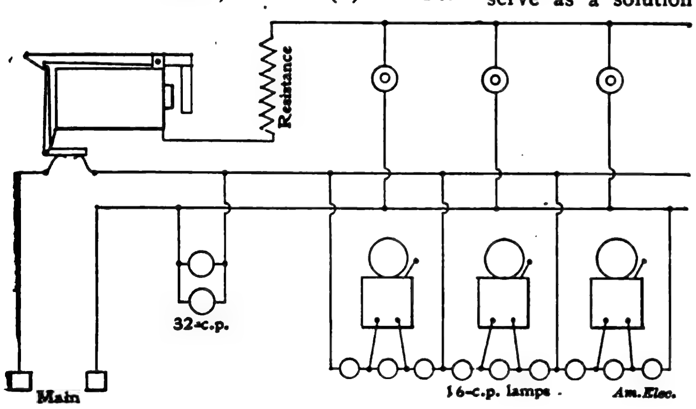

FIG. 3.—MR. MERRILL'S SOLUTION.

connect the local circuits to either of the supply circuits for charging. The switch *5* is used to cut the large cells in or out of circuit with the portable battery; the others, *2*, *3*, *4*, serve to put any one or two or all three of the large cells in the local circuit. By leaving the switch *1* open, closing *5* to the right and properly manipulating the other three switches and the rheostat, the portable battery can be charged from the large cells.

Ironwood, Mich. LOUIS J. GORILLA.

[Mr. Gorilla's diagram being identical with that of Mr. Fiske, the one engraving has been used to illustrate both solutions.—EDITOR.]

The enclosed sketch (Fig. 5) is submitted as a solution of Mr. Lincoln's problem. A double-pole, double-throw switch, *S*, is used to connect the battery circuit to either of the supply circuits, *A* and *B*, or to disconnect from both. With *S* open, the large cells can be connected to the portable battery for charging the latter, in any desired combination, by manipulating the three-point switch *N* and the four-way switch *M*. With *S* closed to one of the supply circuits, the two batteries may be charged in series by leaving *N* open and setting *M* on the extreme right-hand point. If it be desired to charge the portable cells from one of the supply circuits, this may be done by setting *M* on the extreme left-hand point, leaving *N* open, and closing *S* to the desired supply circuit.

Detroit, Mich. FRANK JOHNSON.

[Mr. Lincoln's solution of his problem is shown by Fig. 6.—EDITOR.]

Mr. Petry's Wiring Problem.

The accompanying diagram (Fig. 1) is one solution of Mr. Petry's problem published in the May number. The diagram is practically self-explanatory; the push-button *P* throws the shutter *S*, and depressing any one of the station buttons restores it by means of the auxiliary coil *R*. The two lamps are indicated at *L*.

Washington, D. C. N. P. BETHEL.

Assuming that Mr. Petry intended that his shutter should be set by hand and released electrically, the enclosed diagram will serve as a solution of his problem. The 32-c.p. lamps are shown connected in series, it being assumed that low-resistance bells and shutter winding will be preferred, but they could, of course, be put in parallel with each other if the other resistances in the circuit were too high. Only two bells and push-buttons are shown, but it is a simple matter to add the requisite number of each in parallel with these two.

Louisville, Ky. JAMES B. DILLON.

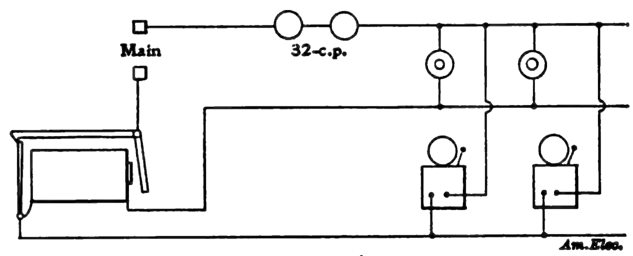

FIG. 2.—MR. DILLON'S SOLUTION.

I offer the enclosed diagram in solution of Mr. Petry's problem. The 32-c.p. lamps are used as pilots and the bells are connected each in shunt to one of a series of three 16-c.p. lamps in order to obtain the

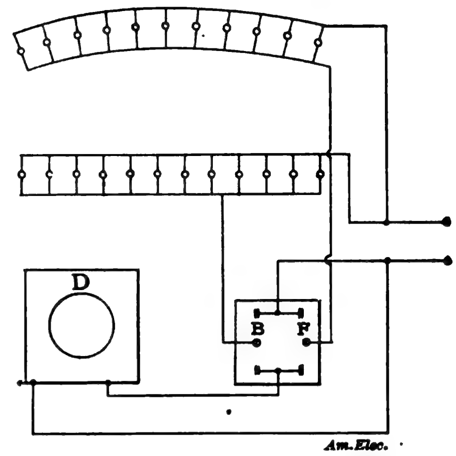

FIG. 2.—MR. GORILLA'S SOLUTION.

low e.m.f. necessary to operate them. The remainder of the diagram is self-explanatory. It might be advisable to use larger lamps than 16 candle-power for reducing the voltage to the bells, unless the bell magnets are wound with smaller wire than ordinarily. I have used this method of supplying bells from electric lighting circuits with complete success, but always had to use high-resistance bells.

Wilmington, Del. WM. MERRILL.

Mr. Converse's Stage Lighting.

Mr. Converse's problem in stage lighting connections is solved by the use of two double-pole, double-throw switches connected to the footlights, border lights and dimmer, as shown by the enclosed sketch (Fig. 1). The switch *B* connects the border lights directly to the supply circuit when thrown upward, and to the circuit in series with the dimmer when closed downward. The switch *F* controls the footlights in exactly the same manner.

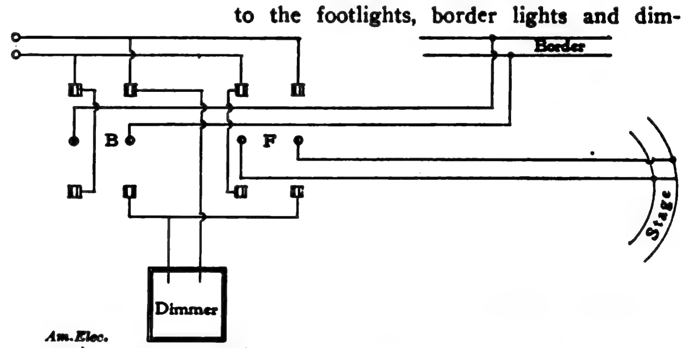

FIG. 1.—MR. BETHEL'S SOLUTION TO MR. CONVERSE'S PROBLEM.

Washington, D. C. N. P. BETHEL.

[The same solution was supplied by Messrs. F. S. Brewer, Newark, N. J.; W. A. Loveland, Philadelphia, Pa.; J. W J. Manning, South Boston, Mass., and Chas. B. Wilson, Chicago.—EDITOR.]

Referring to Mr. Converse's problem, I would suggest the solution shown by the accompanying sketch (Fig. 2). Two single-pole, double-throw switches, *B* and *F*, are used; to burn the border lights brightly, the switch *B* is closed upward, and to dim the border lights it is closed downward. The switch *F* controls the footlights the same way. Obviously both groups may be dimmed simultaneously by throwing both switches downward.

Ironwood, Mich. LOUIS J. GORILLA.

[The same solution was supplied by Messrs. E. S. Lincoln, Brookline, Mass.; Jack Maury, Rossville, Ill., and Geo. C. Ohlin, South Omaha, Neb. It agrees with the author's own solution of his problem.—EDITOR.]

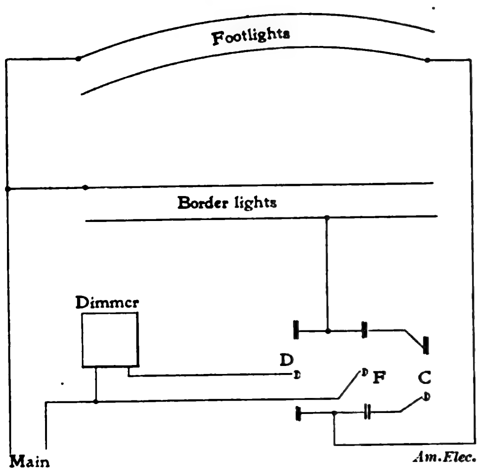

FIG. 3.—MR. BRODE'S SOLUTION.

To solve Mr. Converse's problem, I would suggest using two single-pole, single-throw switches connected as shown by the accompanying diagram (Fig. 3). With the switch *C* open, the switch *F* will put either of the groups of lamps directly on the supply circuit and the switch *D* will connect either of them through the dimmer; closing *C* couples the two groups together, so that they may be put directly on the circuit or through the dimmer simultaneously.

Colton, Cal. L. P. BRODE.

The agreement of switches shown by the enclosed sketch (Fig 4) is one solution of Mr. Converse's problem. Closing the switch *1* downward and *2* upward puts the border lights directly on the circuit; then changing *1* to the upper jaw puts them through the dimmer. Closing the switch *1* downward and *3* upward puts the footlights directly on the circuit, and shifting *1* upward puts them through the dimmer. With *1* closed downward and both of the others closed upward, all the lamps are directly on the circuit, and shifting *1* upward puts them through the dimmer together. By closing *2* and *3* downward the two groups are put in series to the switch *1*, which will connect them directly to the circuit or through the dimmer.

Kingston, R. I. HERBERT A. FISKE.

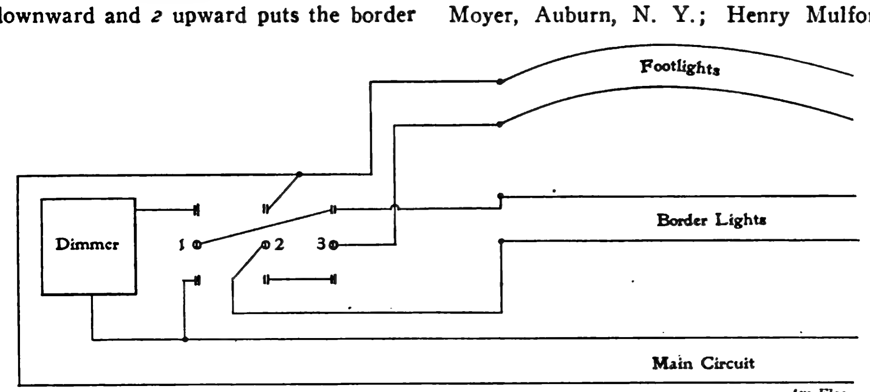

FIG. 4.—MR. FISKE'S SOLUTION.

Mr. Deighmiller's Meter Reading.

The reading of Mr. Deighmiller's meter dials published last month is 49,992; since the pointer of the 100's dial has not completed its revolution, the one of the 1,000's dial must lie between 9 and 0, and the hand on the 10,000's dial lies between 9 and 0 also, so that the hand of the 100,000's dial must lie between 4 and 5. The indication of the 10's hand is obvious.

Boston, Mass. DONALD BOWMAN.

I would read Mr. Dieghmiller's meter 49,992. When the 10's hand completes its revolution the 100's hand will go to 0, and the next two hands will do likewise; the 100,000's pointer then will be at 5, and the reading will then be 50,000. Until then, the indication must be one less on all the dials except the 10's, which plainly is at 2.

Louisville, Ky. JAMES B. DILLON.

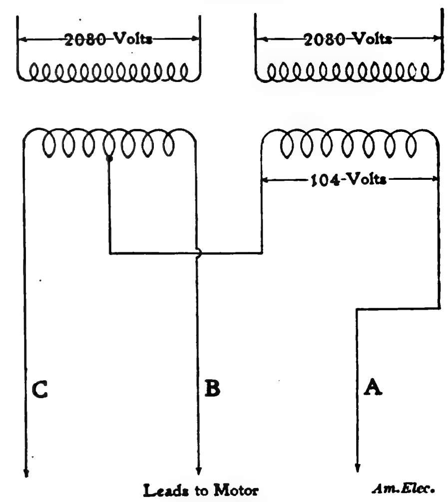
Referring to Mr. Deighmiller's tricky meter reading I should say that the reading is 49,992. The first dial (on the right) is evidently just beyond 2, so that the next pointer must be just beyond 9, but it has not yet reached 0. Consequently the next two pointers must be read 9, and the last one has not yet reached 5, so that it is to be read 4.

New York. JACOB GLOGAN.

The correct reading, but without any explanation, was also supplied by Messrs. F. S. Brewer, Newark, N. J.; G. F. Erfurth, Fort Smith, Ark.; Herbert A. Fiske, Kingston, R. I.; Jack Maury, Roseville, Ill.; Wilson A. McCown, Ladonia, Tex.; Miss Laura J. Moyer, Auburn, N. Y.; Henry Mulford, Patchogue, L. I.; Robert E. Noyes, Schenectady, N. Y.; A. P. Royal, Ellsworth, Me.; Gilbert G. Ryneas, Ambler, Pa., and Leon C. White, Brattleboro, Vt.—EDITOR.

A Transformer Trouble.

A customer on our system has a 110-volt three-phase induction motor supplied with current from transformers which are Scott-connected to get three phases from two, as



A TRANSFORMER TROUBLE.

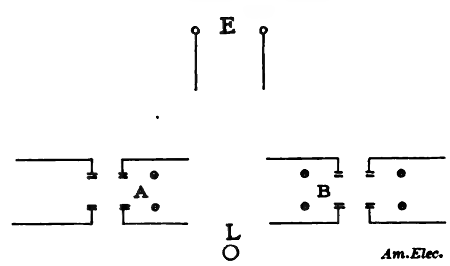
shown by the sketch herewith. It was desired to supply three 16-c.p. lamps from the same mains that supplied the motor, but when the connections were made the following difficulties developed: With one lamp connected across *A* and *B*, we got 104 volts, but with three connected there, only 30 volts; the same results were obtained with connections to wires *A* and *C*, but across *B* and *C* we could get no voltage. It may be of interest to some readers of this journal to figure out what the trouble was. It was soon found and remedied.

RALPH RYDER.

New York.

Problem in Switch Connections.

The accompanying diagram represents an incandescent lamp, *L*, two single-throw, double-pole knife switches, *A* and *B*, and the main entering terminals, *E*. It is desired to make connections between these so that when either one of the switches is



PROBLEM IN SWITCH CONNECTIONS.

closed to light the lamps in its circuit (not shown in the diagram because they do not affect the problem) the lamp *L* will also light at full candle-power. Its voltage is the same as that of the supply circuit *E*. The two lamp circuits supplied through the switches *A* and *B* must not be cross-connected when the switches are open; they are necessarily connected, of course, with the switches closed.

GEO. W. MALCOLM.

Brooklyn, N. Y.

Questions and Answers

Inquiries not accompanied by the name and address of the inquirer, will not receive attention.

Will an induction motor start with a load if thrown directly on the line without any compensator? (2) What is the function of the compensator? W. H.

Yes, but it will take a terrific rush of current in doing it. (2) It reduces the voltage at the terminals of the motor and thereby reduces the initial rush of current.

Is it necessary to run all four wires of a two-phase line in the same conduit pipe, or can they be separated in two pipes? (2) If all four wires are in one pipe, what would be the effect of an unbalancing of the circuits? J. M. D.

It is preferable, but not absolutely necessary to put them all in one pipe. (2) There would be no effect on the inductive drop in the line.

How can a four-cycle single-cylinder gas engine be made to run steadily driving a dynamo? (2) Is not a two-cylinder engine better for that class of work? C. F. K.

By putting on a much heavier fly-wheel. (2) Yes, so far as uniformity of angular effort is concerned; excellent results are obtained, however, with two-cylinder, four-stroke-cycle engines.

Can a voltmeter be used instead of a galvanometer in a Wheatstone bridge? (2) What size of resistance wire should be used in a bridge for use at an e.m.f. of 10 to 20 volts? H. W. B.

Yes, but it will not be sufficiently sensitive for close work. (2) This depends on how much resistance you wish and what the divisions are to be. Probably No. 36 wire will answer in the high-resistance coils and No. 28 in the low-resistance section.

What class of apparatus is preferable for supplying an organ bellows with air, the apparatus being driven by an electric motor? (2) Can an air-pump equipped with an automatic regulator be used? F. V.

Both motor drive direct to the bellows "blow-shaft" and motor-driven centrifugal blowers of special design are used; the preference depends to a large extent on the location of the blowing apparatus with respect to the body of the church. (2) No.

How is the constant derived that is used in the formula for the temperature rise of an electrical conductor due to the current it carries? (2) How do the induction coils in the 40-volt central energy system of the Stromberg-Carlson Company differ from those used in the Hayes 24-volt system? L. P. M.

By experiment. (2) Induction coils at subscribers' stations are not used in the Haynes system; repeating coils are used at the exchange.

If a 60-cycle meter be put on a 90-cycle circuit, would its accuracy be affected? (2) Would an arc lamp consume more or less current if taken from a 60-cycle to a 90-cycle circuit? J. I. McG.

Probably; it depends on the type of meter. See answer to W. G. B. (2) A series-wound lamp would take the same current; a shunt-wound lamp would take less current and carry a longer arc and a differential lamp would probably do the same.

A series arc-lighting circuit equipped with an automatic reactive regulator when thrown on either "phase" of a two-phase alternating primary circuit causes a drop of 5 volts in that "phase;" why does this occur, and how can it be remedied? E. J. A.

The extra drop is due to the inductive character of the arc-lighting circuit; the regulation of an alternator is much poorer with a heavily inductive load than with a non-inductive one, or one of very high power factor.

What is wattless current? (2) What is the use of synchronous frequency changers? (3) What is a composite-wound alternator? E. M.

A current which is out of phase with its e.m.f. by one-quarter of a cycle. (2) To change the frequency of a supply circuit, so that apparatus requiring different frequencies may be supplied from a single generator or set of bus-bars. (3) An alternator having a compound-wound field and so arranged with its exciter as to regulate for changes in the power factor of the work circuit as well as changes in the load.

Please give instructions for making a magnet not over 2½ inches long to lift ½ pound a distance of ⅛ inch, with 5 volts at the terminals. H. W., Jr.

Use a stopped solenoid of the type described in the March number, with the following dimensions: plunger and core scant ⅜ inch diameter; yoke of strap iron ¼ by 1 inch cross-section; distance from top to bottom of yoke 2 inches; brass center tube ⅜-inch bore, full, and ½-inch outer diameter. Coil of No. 15 single cotton-covered magnet wire, wound to an external diameter of 2 inches.

What is probably the cause of a compound-wound generator dropping its voltage when the load is cut off? (2) What causes burnt spots on a commutator running with carbon brushes? D. E.

Its construction; that is exactly what it is intended to do. (2) Any one of several defects or a combination of some of them; the most common causes are loose leads in the commutator lugs, high mica between bars, inadequate connection between the brush and the stud, too light a tension at the brush springs, improper setting of the brushes, and poor design of the armature.

How can a 10-ampere arc-lighting dynamo of 30 lamps capacity be altered to maintain enclosed-arc lamps requiring 70 volts and 6.8 amperes? The 10-ampere lamps required 50 volts each. The armature is wound with No. 16, the field magnet with No. 9, and the regulator with No. 18. E. & C.

Rewind the armature with No. 18 wire, putting 1.4 times the present number of turns in each coil; rewind the field coils with 1.4 times the present number of turns, using No. 11 wire, and rewind the regulator with 1.4 times the present number of turns, using No. 20 wire. The speed will remain practically the same as before.

How can I ascertain the number of magnetic lines of force passing through the magnetic circuit of a motor? G. W.

Run the motor without any load and measure the speed accurately; multiply the revolutions per second by the total number of wires all around the armature core (number of commutator segments × turns per coil × 2); divide the voltage at the brushes by the product of speed and wires and multiply the result by 100,000,000. This is for a lap-wound armature; if the machine is multipolar and the winding is wave-connected, divide the final result by half the number of field magnet poles.

Would not the core of an induction coil be better if it were continuous, forming a closed magnetic circuit? (2) Where can I obtain flint glass and tinfoil suitable for making high-voltage condensers? (3) If two Leyden jars were charged from a high-voltage transformer and discharged through a discharger, should the latter be wound, and if so, how? C. O. W.

No; because it would not demagnetize quickly enough when the primary circuit is interrupted. (2) Probably from the Pittsburg Plate Glass Company and the Conley Foil Company, respectively, both of this city. (3) It is impossible to charge a condenser from a transformer and disconnect it with the charge in it.

Can a machine be used both as a dynamo and as a generator? W. J. G.

There is no difference between a dynamo and an electric generator.

What is the difference between the power factor of a single-phase system and that of a three-phase system of the same voltage and frequency, each supplying 5-hp. induction motors of the same make? (2) What is the chief objection to supplying lights and motors from the same single-phase alternator? G. H. L.

The power factor is determined by the combined power factor of all the motors and the line, not by the number of phases. Without knowing the joint power factor of the motors, the frequency of the supply, the length of the line and the distance between wires, your question cannot be answered. (2) The fluctuation of voltage due to the throwing on and off of the motors.

Does the frequency of the supply current affect the speed of an integrating watt-hour meter of the induction type? (2) If so, what would be the effect of changing from 133 cycles to 60? W. G. B.

To a slight extent, but the speed is not proportional to the frequency like that of an induction motor; changing the frequency changes the phase relations of the two magnetic fields and thereby affects the torque and speed somewhat—more than a negligible amount. (2) The exact effect cannot be predetermined without the full knowledge of the motor characteristics of the machine; its accuracy would be seriously impaired, and in order to avoid this, the compensating coils should be changed to correspond to the change in frequency.

Is it good practice to connect up distributed transformers to a common secondary main, the primary mains being 2200 volts and the secondary 110 volts; or is it better to have each transformer supply a separate main distributing current to a restricted locality? (2) With the transformers all in parallel at the secondary side and lightning arresters at the station, would there be any greater liability of crippling the system in a thunder storm than with the separate secondary mains? G. H. B.

It is not particularly bad practice to work the transformer secondaries all in parallel, if each one is properly fused in both primary and secondary, but this arrangement is open to the objection that the sudden disabling of one or two large transformers during the maximum load period will overload all the others on that secondary line. It is much preferable to let each transformer supply a separate secondary main, using transformers large enough to cover a considerable distribution area each. (2) Yes, slightly.

NEW WESTINGHOUSE CRANE MOTOR.

The Westinghouse Electric and Manufacturing Company has been closely identified with the problem of crane and hoisting service and has been actively engaged in the construction of electric crane machinery for more than a decade. The company's "Type K" motors are designed for the operation of cranes, hoists and similar apparatus and for intermittent service in which heavy starting torques and wide speed variation are required. Ten sizes are standard, including capacities from 2 to 40 horse-power. The frames are of the wholly enclosed form, so designed that the working parts may be exposed for inspection or adjustment without dismantling. If local conditions permit, the cover about the commutator may be removed and the motor operated open, with improved ventilation and increased capacity.

FIG. 1.—WESTINGHOUSE "TYPE K" CRANE MO TOR.

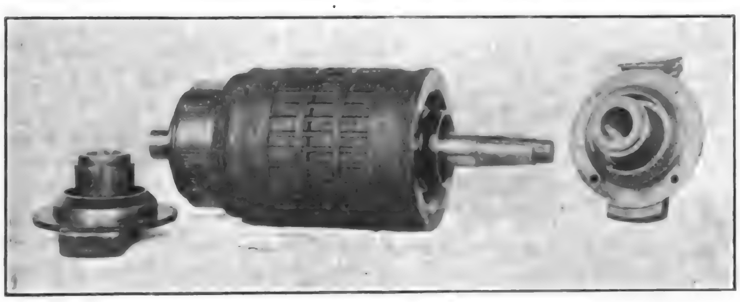


FIG. 2.—ARMATURE AND BEARING HOUSINGS.

FIG. 3.—WESTINGHOUSE "TYPE K" CRANE MOTOR.

Type K motors have four inwardly projecting poles, each of which is magnetized by a separate field coil. The motors are series wound and are designed for operation on direct current circuits of 220 and 500 volts. Since the current passes successively through armature and field winding, the torque of such a motor increases nearly as the square of the current up to the point of saturation of the iron. Governed by change of voltage at the motor terminals, the speed of the motor is carried through a wide range, the change in the resistance of the motor circuit being made by means of a controller.

The motor frames are of cast steel (except in the three smallest sizes, where they are cast iron). They are nearly square in section and require only a small amount of head-room on a crane, or floor space when used with hoists or similar apparatus. The frame is built in two parts, divided in a plane passing through the axis of the armature and at an angle of 34 degrees with the horizontal, an arrangement which allows the upper half of the field to be removed without disturbing the gears or shaft, and makes it easy to take out a pole piece and field coils, or to remove the armature. The lower half of the frame has four feet, with holes for bolting to the support. The lower casting has also two finished faces to which bearings for a countershaft may be bolted or which may be used for side mounting. The commutator end of the frame is connected to the poles by six ribs, any two of which may carry the brush holders. The opening around the commutator is entirely closed by a 3/32" sheet steel band, fastened by thumb screws.

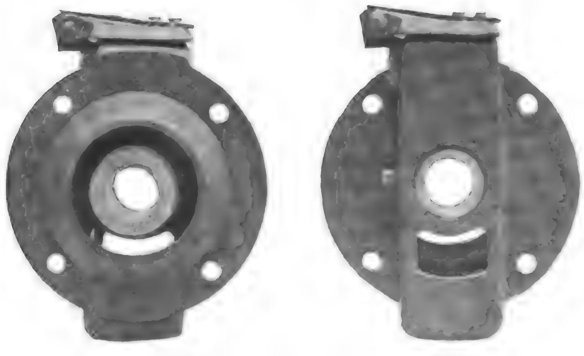

FIG. 4.—BEARINGS AND BEARING HOUSINGS, WESTINGHOUSE "TYPE K" CRANE MOTOR.

The four pole pieces are built up of soft steel punchings, riveted together between wrought iron end plates, and are secured to the frame by bolts which pass well into the punchings but leave the pole face smooth and unbroken. The coils of the larger motors are of copper strap and the terminals are insulated with asbestos ribbons. The coils are fitted to the pole pieces, protected at the ends by oiled duck and held in place by the spreading tips of the pole pieces. Shells lined with bronze or babbitt and mounted in housings which may be removed without separating the motor frame, constitute bearings. Great strength has been provided, with the wear distributed over a large surface, so that the bearings are suitable for the most severe service. Cast brass bearings are standard on all sizes up to and including the No. 4; on all frames above No. 4 babbitt bearings are used. Grease lubrication is employed in all except the larger sizes—the bearings of which are designed for lubrication by oil and waste. Drip cups are provided under the bearings for all motors.

The armature core is built up of soft steel punchings, carefully annealed. These punchings are, in all except the smallest sizes, assembled on a spider and held from turning by a steel key. The pinion end is provided with a bell-shaped flange, which forms a support and shield for the armature coils. Ducts between the punchings are provided

through which air, drawn in through openings in the spider, is forced out against field coils and core, maintaining a uniform temperature throughout all parts of the motor. The commutator is mounted on the armature web, allowing the shaft to be removed without disturbing the winding or connections. Covers of oiled duck adequately protect the end of the winding. Wiper rings or oil guards are provided at each end of the armature to protect the winding from oil.

The commutator is built up of bars of hard drawn copper, insulated by prepared mica, and mounted in the armature spider. The commutation is claimed to be good, in spite of the heavy rushes of current to which a motor of this class is subjected. The brush holders are of the sliding type. The individual holders may be independently adjusted. Tension is provided by means of a coiled spring which acts through a short brass strip, so that the spring responds immediately to any movement of the brush. The brush holder arms are secured by stud bolts to surfaces which are machined on the ribs of the frame, parallel to tangents at the points of contact with the brushes. Adjustment to compensate for wear of the commutator can be made by removing the iron washers which are placed under the insulating washers on the stud bolts.

With all but the two smaller sizes a shunt is connected to the tip of the spring, extended back over the spring and securely fastened to the brush holder, thus relieving the spring of the duty of carrying current. With every carbon brush ⅝" or more in thickness an additional sheet is provided connecting the carbon itself to the carbon holder.

Flexible leads are brought out through insulating bushings in the upper frame and are either connected to terminal blocks mounted on the top of the motor, or are arranged for direct connection to the controller lines.

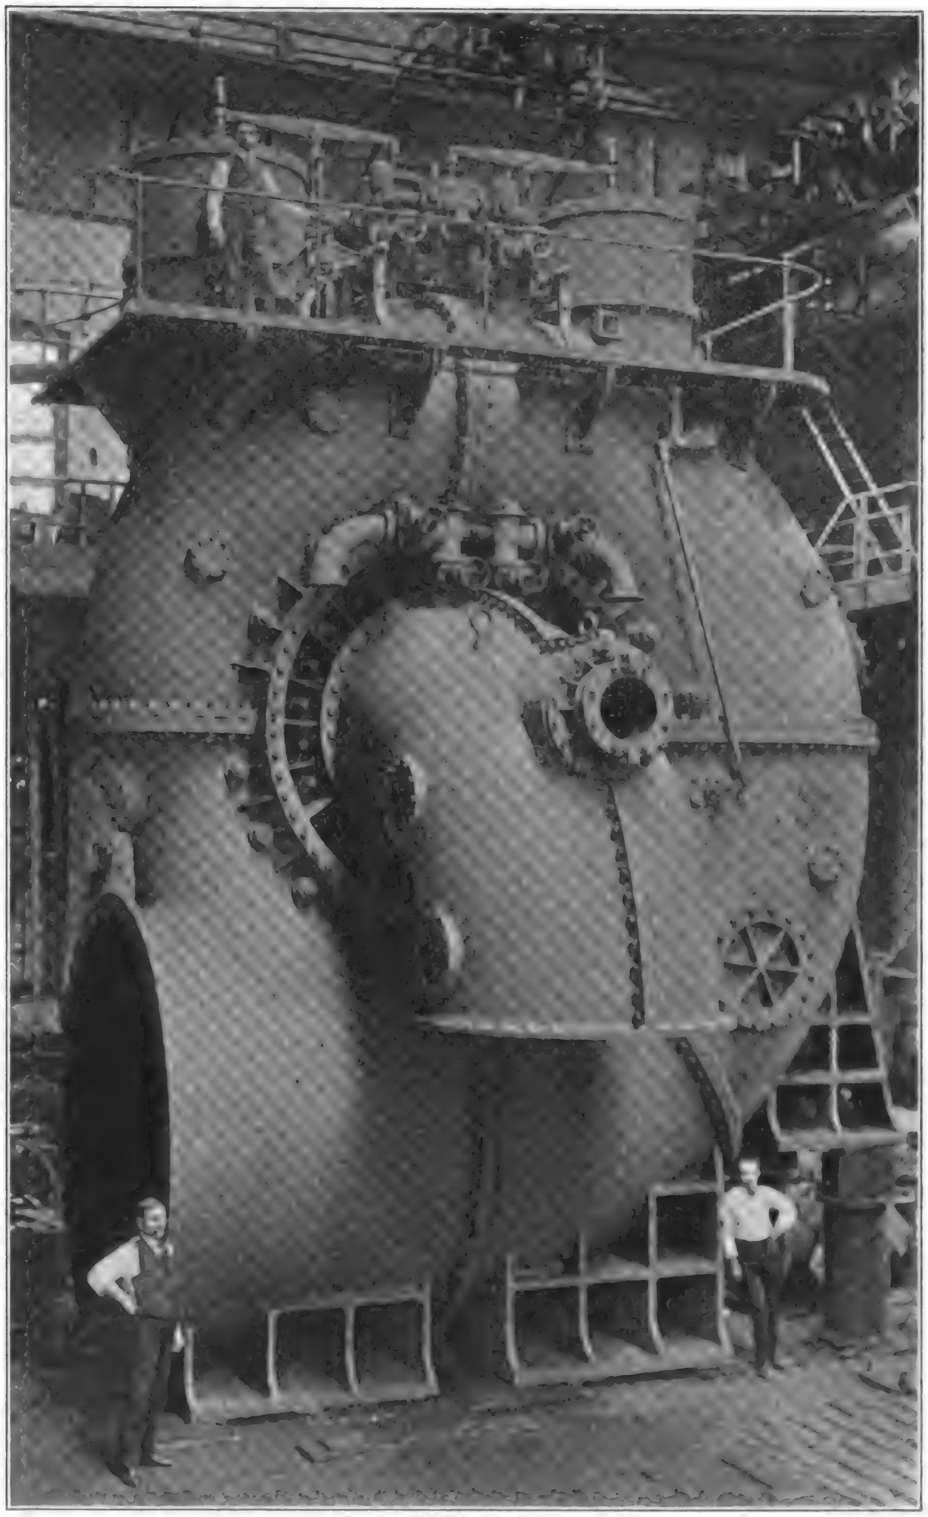
MAMMOTH WATER TURBINE

What is in all probability the largest water turbine ever built is now being installed in the power plant of the Shawinigan Water & Power Company, at Shawinigan Falls, on the St. Maurice River, Canada, by the I. P. Morris Company, of Philadelphia, Pa. The turbine has a capacity of 10,500 horse-power and its huge proportions are well shown in the accompanying engraving. The machine is 30 feet from base to top, 22 feet wide over all, and 27 feet from center to center of the two shaft bearings. Its total weight is in the neighborhood of 182 tons. The shaft, which is of forged steel, is solid and weighs 10 tons. It is 32 feet 3½ inches long, 22 inches in diameter at the center and tapers to 16 inches on the generator side and 10 inches in diameter on the other side. The runner of the wheel is of bronze and weighs 5 tons.

The quantity of water necessary to operate the turbine when under full load is enormous, no less than 400,000 gallons passing through per minute. This amount of water represents a river 100 feet wide, 9 feet deep and flowing at the rate of 60 feet per minute.

The turbine is of the horizontal-shaft, inflow-axial type, with spiral casing and a draft tube on each side, through which the water discharges outward from the center. The water enters the turbine through the intake 10½ feet in diameter, at the bottom of the turbine. It flows around and fills the outer spiral tube and then passes in radially through an annular set of distributor vanes and then through the wheel, and, diverging, finally discharges right and left through two large draft bends one on either side, of which one is shown in the engraving. Just outside these bends are situated the bearings of the shaft on separate pedestals not shown. What appears in the view is simply one of the two stuffing boxes through which the shaft (not shown) passes.

It will be noticed that although the diameter of the intake is 10½ feet at the bottom, the sectional area gradually diminishes as the water passes around the tube, the diminution being proportionate to the amount of water that flows through the wheel as its circumference is traversed. The two cylinders on top of the turbine contain the pistons which, operated by hydraulic pressure under the control of the governor, move the set of distributor vanes which regulate the supply of water to the runner for various



10,500-H. P. WATER TURBINE FOR SHAWINIGAN FALLS.

loads. The vanes, twenty-four in number, are hollow castings of bronze with a projected area of about 20 × 24 inches and have a small angular range of motion about steel pins passing through them and secured to the casting upon either side. They are connected by links to two large annular rings, one on either side, which move on ball bearings. Each ring is in turn connected by a rod to each of the two pistons, whose movement thus controls the angular position of the distributor vanes.

Some idea of the great force required to move these distributor vanes against the pressure of the water may be obtained from the manufacturer's statement that each of the pistons above was designed to exert a maximum pull of 100,000 pounds. The amount of power required to govern a turbine unit of this gigantic size is so great that the usual types of governors, hand-gear mechanism and controlling levers could not be used. The arrangement of powerful hydraulic engines and controlling devices adopted to meet this case is of original design and possesses many novel features.

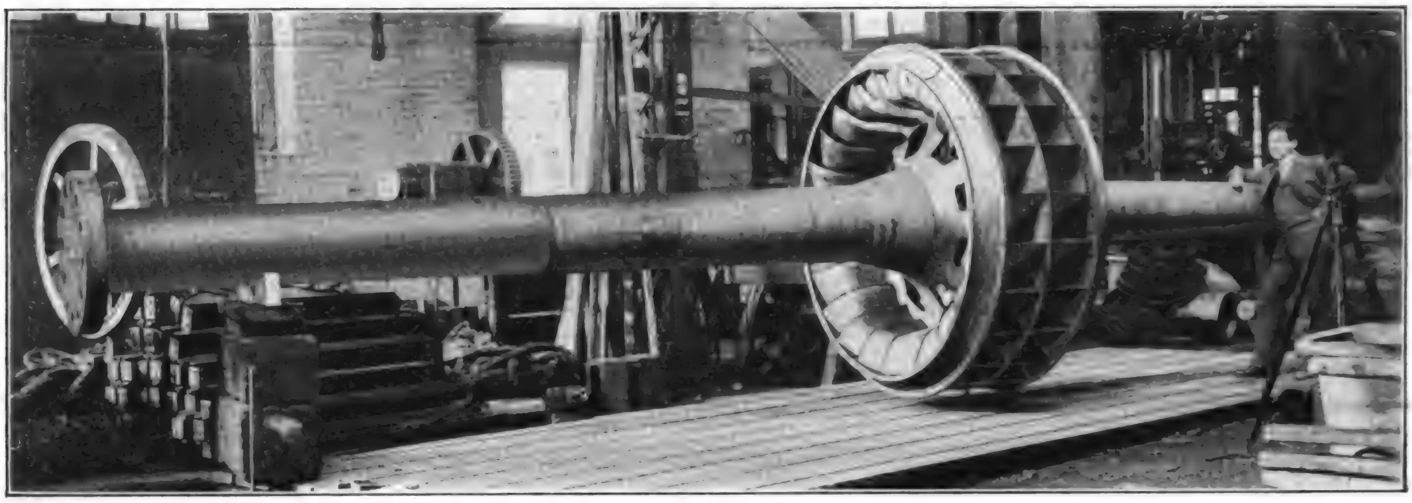


FIG. 2.—RUNNER AND SHAFT OF WATER TURBINE.

THE WILKINSON STOKER.

In the automatic stoker illustrated herewith, crushed or slack coal is fed into the hopper and mechanically forced down an easy incline under a kindling arch. It passes thence through various zones of heat and combustion, until it rests on the ash table, where final combustion takes place before it falls onto the ash slide. The incline is provided by heavy hollow grate bars having an alternate forward motion of about ¾ in. to 1 in. The surface of the bars is stepped, and

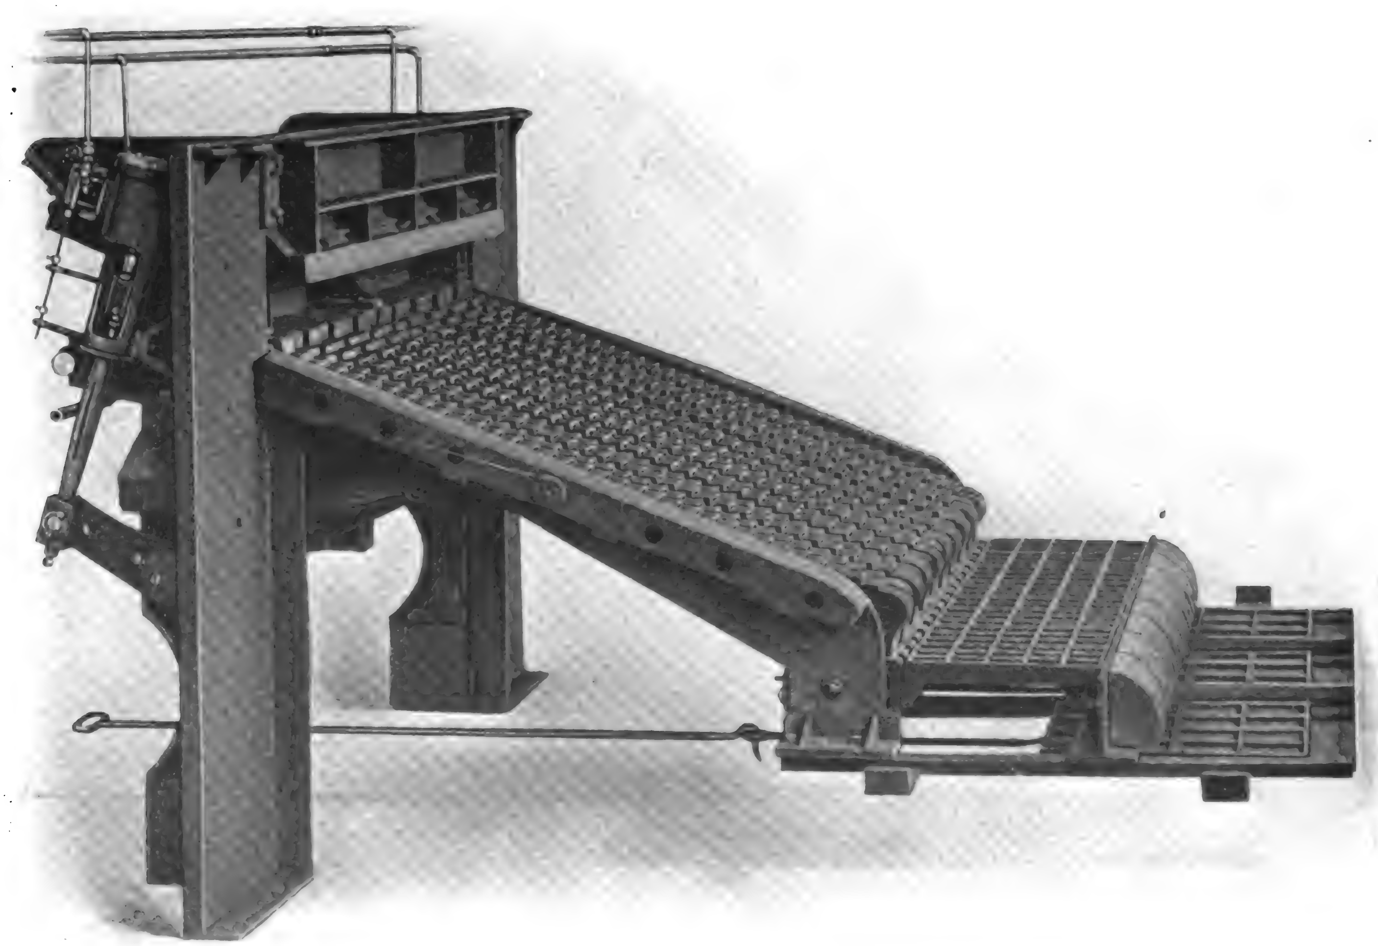

FIG. 1.—WILKINSON AUTOMATIC STOKER.

an alternate up and down and forward motion of one grate passing the other is provided. Introduced into the end of each hollow grate bar is a small steam jet, and this steam with the air which it sucks passes into the fire through openings in the rises of the steps mentioned.

The constant sawing action of the grate bars causes the fuel to travel forward and downward accompanied by steam and air. The combustion secured is said to be highly gaseous. The steam jet is automatically regulated in proportion to the boiler loads and requirements, the action being intense when the boiler is under a heavy load. The chief purpose of the steam jets is to preserve the grate bars from destruction. They also secure, it is claimed, a gaseous furnace combustion, disintegration of clinkers, and enable the use of grate bars set close together and avoid the waste of fine fuel.

The hopper, inclined hollow grates, ash table, ash slide, motor and driving mechanism are all shown in the illustration. The simplicity of the mechanism is evident. The stoker is driven by two small hydraulic motors, water to drive which is furnished by a small pump and tank located conveniently in the boiler room. The water is used over and over again. The power required is said to vary from ½ to 1½ per cent. Repairs may be made while the stoker is under fire by simply pushing the fire over the bar to be repaired to one side, stopping the stoker for a few minutes to unloose a pin under the stoker, when the injured bar can be taken out.

The mechanism of the stoker is illustrated so graphically in Fig. 2 that an extended explanation seems unnecessary. The fire-brick arch is furnished with the stoker. Coal having been placed in the hopper passes under the drop plate, and then down the grates, beginning to ignite and coke at a

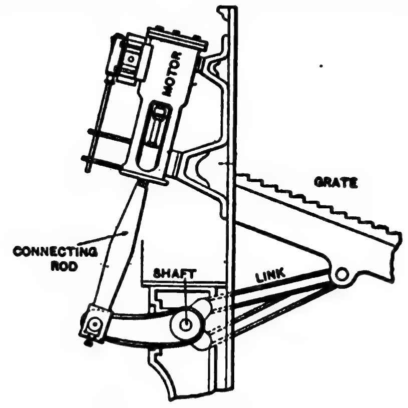

FIG. 3.—DRIVING MOTOR.

point A. A higher zone of combustion is reached at N, while at C a zone of practically white heat is said to be found when a heavy load is being carried. The partly burned out ashes land at D, where they give off their final heat, thence falling on the ash slides at E, whence they are removed by pulling out the ash slides.

The grate bar, a small section of which is given, weighs from 160 to 210 pounds according to the size of stoker, the length of bar being proportioned to the grate surface required. The stoker is adapted for slack, buckwheat and pea anthracite coals or bituminous slack. Regarding the excessive use of steam in the jets, the maker claims to have tested the stoker thoroughly and that with a steam jet the evaporation was 10.15 lbs. of water per pound of coal burned, while with a blower the evaporation was 9.22 lbs. These results were obtained while running the boiler 57 per cent. above its rating.

The grate bars are very heavy and in the rise of each step is an opening about ⅜ by 2½ ins. The surface of the grate exposed to the fire is said to be made of special iron suitable for high temperatures. Operated with ordinary intelligence the maker maintains that the cost of repairs should not exceed ½ of one per cent. of cost of investment per year. The stoker is built by the Wilkinson Manufacturing Company of Bridgeport, Penn.

INTEGRATING WATT-HOUR METER WITH PREPAYMENT ATTACHMENT.

The Fort Wayne Electric Works of Fort Wayne, Ind., have brought out a new single-phase integrating watt-hour meter, which, while intended primarily as a prepayment meter, may, by the substitution of a different base and case, be used as an ordinary induction watt-hour meter. All line connections are made inside a sealed terminal box on top of the meter to binding posts protected from accidental short-circuits. A four-dial register is provided which indicates the kilowatt-hours directly, no constant being necessary.

The Type-W meters are designed for 110 and 220-volt two-wire and for 220-volt three-wire circuits. The meter is made for four different ampere capacities: *i. e.*, 5, 10, 20 and 40, without transformers. The meter is said to be reasonably reliable and accurate in operation.

The prepayment attachment consists of three main pieces, the operating device, the meter case and the money box. These three pieces replace the case of the ordinary meter and are mounted on the prepayment base. The coin is placed in a slot in the hollow stem behind the knob projecting from the device where it fits into a slot in a stud within the stem. As the knob is turned to the right the coin is locked in as a key which turns the stud and operates the mechanism within the device, placing the coin to the credit of the consumer as shown by a figure above the knob. The knob, once started with a coin

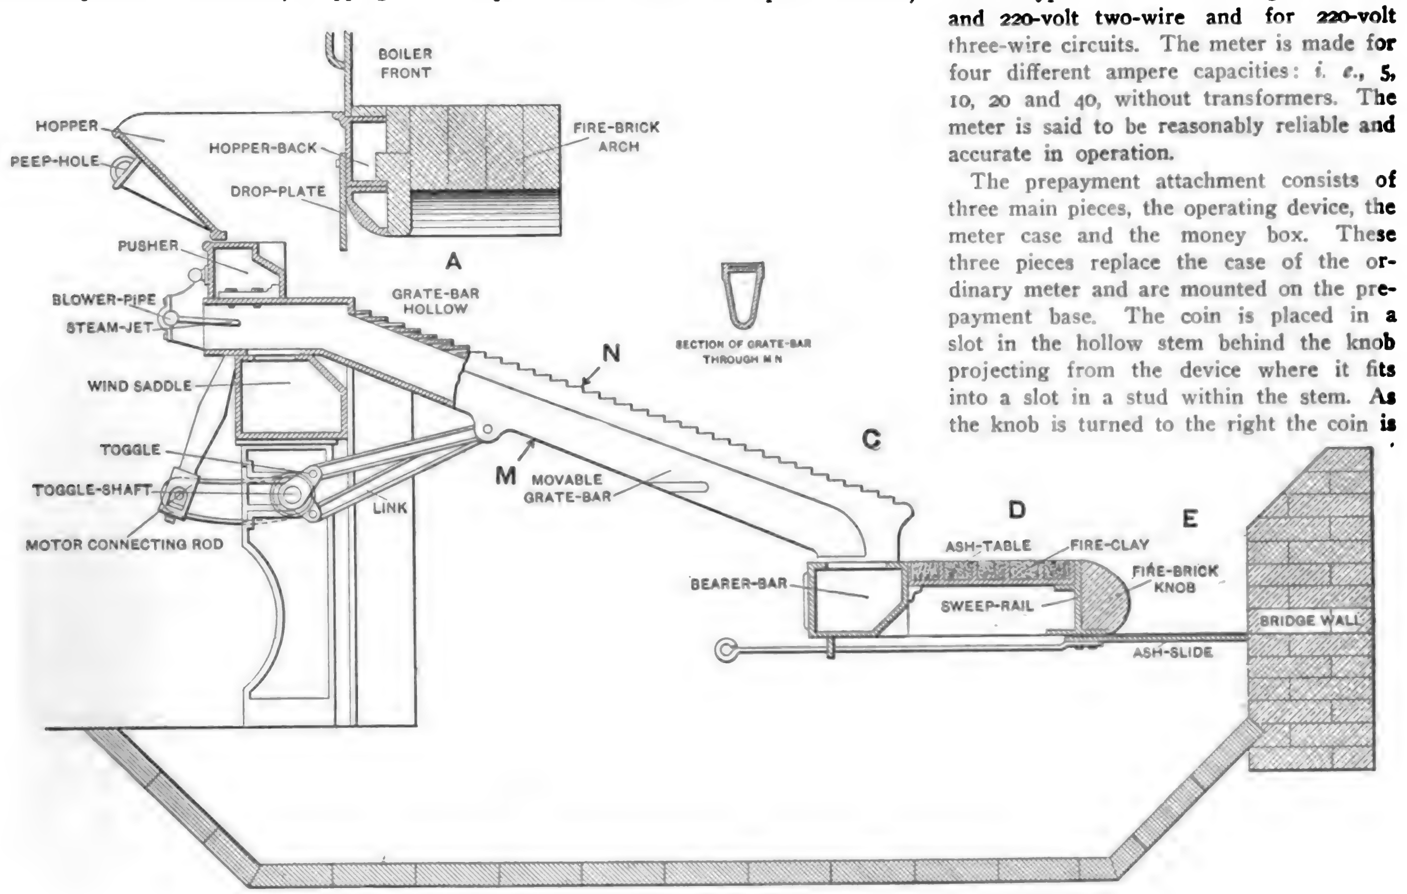

FIG. 2.—DETAILS OF WILKINSON AUTOMATIC STOKER.

locked in, cannot be reversed, but must be given a half turn to release the coin which falls through a tube to the money box below. The coin is locked in as soon as the knob is moved and cannot be abstracted except by unlocking the money box.

The actuating force which operates the device is in a large flat coil spring inside the barrel on the front end of which are the credit figures. The spring has many turns and as the operation of the device never equals one whole turn the spring always exerts a practically constant force.

The rear end of the spring barrel is covered by a disc having an internal and external gear on its rim. The external gear is acted on by the escapement gear in mesh with the registering mechanism of the meter. The internal gear is in mesh with an intermediate gear mounted on the spring barrel and meshing with a pinion on the stud within the knob stem. The function of this combination of gears is to render the operation of the escapement independent of the operation of the credit knob in its effect on the credit indicator. This permits the device to credit and debit simultaneously if the insertion of a coin should happen to coincide with the release of the escapement. The simultaneous credit and debit would leave the figure in the credit window unchanged. In the common operation of the device this condition rarely appears. The insertion of a coin usually occurs when the escapement is locked.

Inserting a coin and turning the knob rotates the intermediate gear and rolls it around on the internal gear of the stationary double-gear disc, carrying forward with it the spring barrel and credit figures. This increases the value of the figures, one for every coin inserted and shows the amount to the credit of the consumer. The debit operation takes place when the escapement is released by the meter register. Then the intermediate gear rolls in the opposite direction around the stationary pinion actuated by the coil spring and turns the credit figures back one place.

If the device is both debiting and crediting, the intermediate gear simply rotates on its axis and since both the pinion and the double-geared disc are rolling on it in opposite directions at equal rates, the position of the credit figures is the same after the operation as before. The capacity of the prepayment device is 20 coins. The coin box has a capacity of about 100 dimes.

When energy to the extent of the credit is consumed, the last escapement opens a four-point switch in the back of the prepayment box and disconnects the meter from the circuit. The switch will remain open until another coin is inserted; when turning the knob closes the switch and credits the coin.

The money box with coin tube is locked to a stud on the bottom of the meter case by an internal lock operated by a small key inserted in a slot. The box can be emptied of coins only by unlocking and removing.

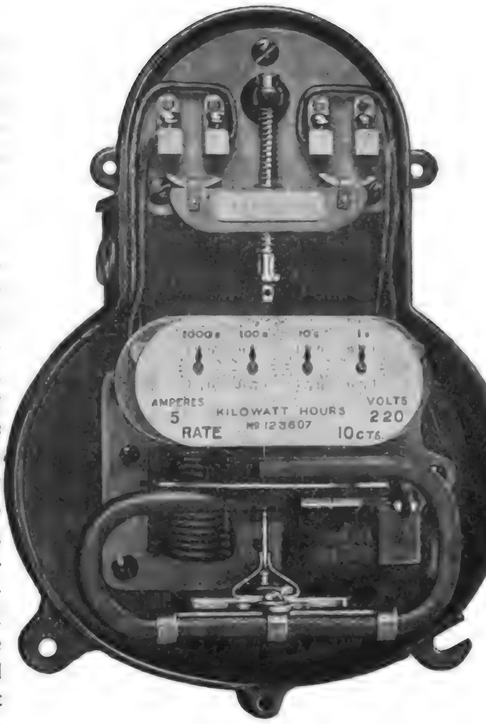

FIG. 3.—PREPAYMENT WATT-HOUR METER.

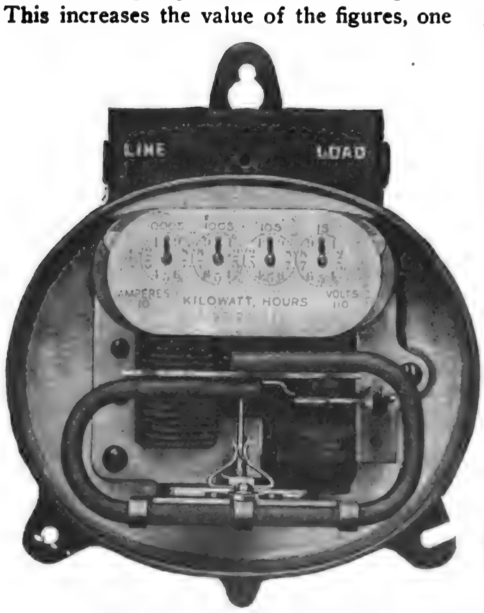
A new release motion or escapment has been employed in this prepayment meter. Its function is to subtract credit at the same rate that energy is consumed, so that when 10 cents' worth of energy has passed the meter, the prepayment device will show 10 cents less credit.

To do this a pinion connection is made with the registering gear of the meter. The pinion shaft carries a small cam which in revolving, oscillates an eccentric arm that rocks on its elbow, advancing and retracting its finger end across the periphery of the release gear wheel in mesh with a damper fan. This advance and retreat requires one whole revolution of the pinion, one half of which is spent in pushing a catch from the pin set in the rim of the release gear. In so doing the finger displaces the catch and the other half turn is consumed in withdrawing the finger from the pin. When the finger has nearly reached its outer position the release gear is free to revolve, driven by the coil spring acting through a train of three gears. The middle gear in this series is large and makes a single revolution for each release. A pin on this gear wheel pushes the catch back into the path of the stop pin on the release gear wheel and arrests its motion after it has made the necessary number of revolutions to allow the coil spring to turn back the credit figures one place.

These three motions—release, revolution and arrest—constitute the functions of the escapement. The release gear wheel, the stop gear wheel and the credit wheel have a definite ratio of speeds, but the frequency of release is governed entirely by the size of the pinion driving the eccentric arm cam and in mesh with the meter registering mechanism.

The operation of the prepayment device adds no work to the meter's load as the only duty performed by the meter registering train is the tripping or release of the escapement movement. This occurs but once for every rate unit, and consists in moving a tiny brass lever about one-eighth of an inch during this period.



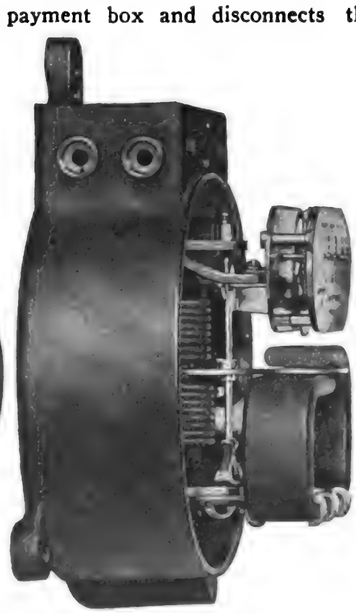


FIG. 1.—FORT WAYNE INTEGRATING WATT-HOUR METER.—FIG. 2.

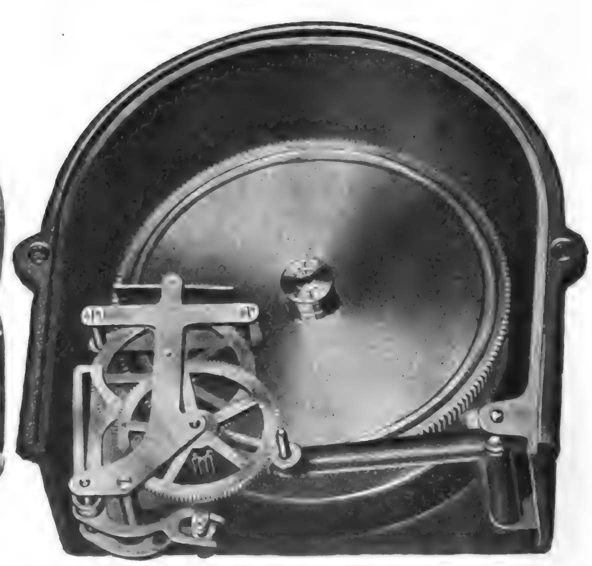

FIG. 4.—PREPAYMENT DEVICE, SHOWING ESCAPEMENT AND SWITCH LEVER.

New Apparatus and Appliances

HIGH-TENSION OIL SWITCHES.

The Hartman Circuit Breaker Company, of Mansfield, Ohio, has for the past four years been developing a line of high-tension oil switches and circuit breakers, and, in the design which is here presented, particular attention has been given to the insulation of the live parts of the switch from the operating mechanism in order that the switch might be installed on the back of the switchboard and used for very high voltages with entire safety to the operator. This has been accomplished by using a new material in oil switch construction, viz., moulded fibre treated by a process which it is said gives to it insulating qualities substantially equal to porcelain. Each pole of the switch is enclosed in a separate tank or cell made of this fibre. The cover of the tank with its two insulators is also made of treated fibre, and the live parts which are enclosed in the tank are completely insulated from the metal supporting frame and operating mechanism. In switches intended for voltages above 6600, the oil tank is moulded in such a way that, together with the wooden switch rod, a complete barrier is interposed between the two arcing points of the switch element. Two, three and four-pole combinations are made up of the single pole element shown in Fig. 1. These are clamped side by side to sections of seamless steel tubing which is fastened rigidly to the switchboard plate. This construction permits of liberal spacing between the poles without increasing the weight of the switch. In the automatic switch or circuit breaker two types are made. In the type shown in Fig. 2 the overload coils are mounted on spools of treated wood and are operated directly from the high potential circuit. This dispenses with the use of current transformers and effects a corresponding reduction in the price of the circuit breaker. The insulation of these coils has been worked out with great care and is entirely adequate for the voltages for which these circuit breakers are recommended. In the second type of circuit breaker which is made, the overload coils are mounted substantially as shown in Fig. 2, and are energized from the secondaries of series transformers. This circuit breaker is made for potentials up to 22,000 volts. Both of these circuit breakers possess the feature that they cannot be closed while an overload exists on any phase of the line. While these switches and circuit breakers were mainly designed for installing on the switchboard, they can also be installed apart from the panel and operated manually by a simple system of cranks and rods, or they can be operated electrically by means of solenoid control. In this case the operating current is derived from the exciters, a storage battery or any convenient source of direct current supply.

FIG. 1.—HARTMAN OIL SWITCH.

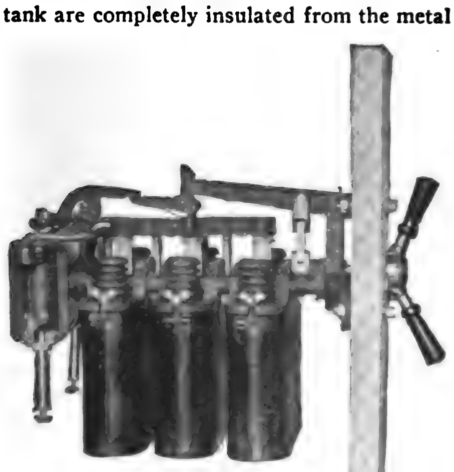

FIG. 2.—OIL SWITCH WITH CIRCUIT-BREAKER.

COMMUTATOR TRUING DEVICE.

Jordan Brothers, of New York City, have developed and placed on the market a commutator truing device which possesses many advantages, chief among which is its ready application to existing machines without the necessity of removing the armature or commutator. The device consists of a grinding wheel mounted in adjustable ball bearings and equipped with appropriate clamps with which to fasten it to the rocker arm or frame of the motor or dynamo. The machine is fastened in position with its shaft parallel to that of the dynamo with the grinding wheel just clearing the commutator. A round belt passes around a driving pulley on the grinding wheel shaft and from there around the end of the commutator or any adjacent revolving portion of the machine. An idler pulley is provided to take up any slack in the belt and to give the proper adhesion. The grinding wheel shaft is movable parallel to the commutator shaft and has sufficient range to sweep over the entire commutator. This shaft is placed on an eccentric sleeve and by the manipulation of the wing nut the grinding wheel may be set in a position to take as light a cut as may be desired. The wheel is slowly fed across the surface of the commutator by means of the handwheel shown. It is evident that the commutator is thereby trued with reference to its center of rotation, which may or may not correspond with the centre marks on the ends of the shaft. The wheel is made of a special composition which is claimed to contain no emery or other mineral injurious to the insulation between the commutator segments. The cut is said to be clean, there being no tendency to drag the copper across from segment to segment. The device is warranted to grind down the copper and mica alike. All parts of the device are interchangeable.

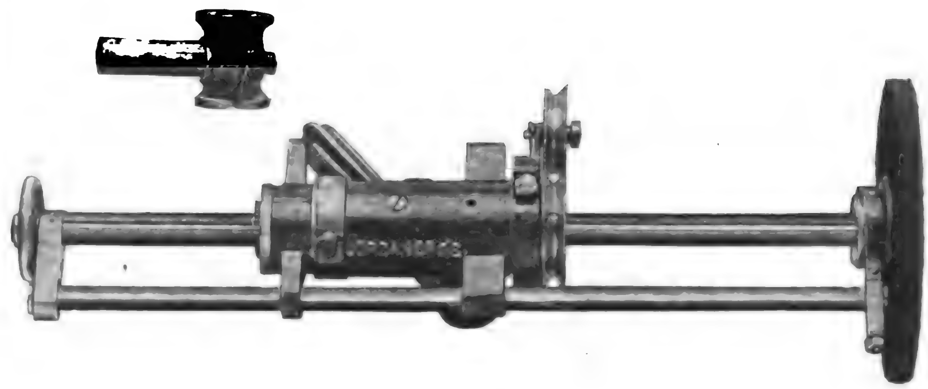

FIG. 3.—COMMUTATOR TRUING DEVICE.

WESTINGHOUSE CIRCUIT BREAKER.

In order to meet the demand for a very compact and inexpensive circuit breaker for both alternating and direct-current circuits, the Westinghouse Electric & Manufacturing Company has produced the type F breaker described below. The circuit breaker is made in 12½, 25, 50 and 75-ampere sizes for 250 volts direct current

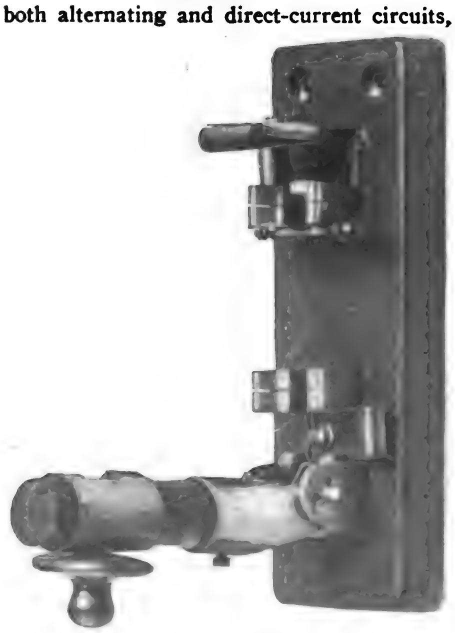

FIG. 4.—CIRCUIT-BREAKER OPEN.

and 440 volts alternating current. They are made in the overload type only. The tripping point is adjusted by turning the thumb screw shown in the illustration, the range claimed being from 80 per cent. to 180 per cent rated capacity. The small insulating knob at the right of the contacts controls a tripping device by raising which the breaker may be opened by hand. By installing a breaker for each wire of the circuit, two for two-wire and three for three-wire circuits, the switch may be dispensed with and the circuit operated by means of the breakers alone. In this case, the breakers are non-closable on overloads, the breaker on one side of the circuit opening when the breaker on the other side of the circuit is closed. An insulating knob is provided for closing. The only depth required in the containing box is that required for the opening of the breaker. Current-carrying contacts are of copper, arcing contacts are carbon and are readily renewable. The lever arm is opened by a spring. The operating solenoid is inside of a fibre tube in the lever arm, which also conduces to a small and compact design. The parts of the breaker are mounted on a neat porcelain block, which is fastened to its support by three screws with countersunk heads. Every effort has been made towards producing a breaker small in size and cost.

FIG. 5.—BREAKER CLOSED.

LINEMAN'S TEST SET.

One of the drawbacks of the magneto in testing is that it gives no idea of the resistance of the circuit other than that it is or it is not greater than that through which a ring can be had with the particular magneto being used. When testing wires in metallic conduits it also frequently indicates a ground when none exists, and two men are required for rapid working. The Whitney tester shown by Fig. 6 was designed to obviate the drawbacks inherent in the magneto, at the same time possessing its good features. It consists of a very simple and strongly constructed voltmeter movement mounted, together with a couple of cells, a small rheostat and a pair of terminals in a small stout box of hard wood. The connections within the box are such that when the cord ends are touched together, the batteries are applied direct to the voltmeter terminals, the rheostat being so adjusted that the voltmeter then shows full scale. Evidently if a resistance were interposed between the terminals, it would be in series with the voltmeter whose needle would then fail to reach full scale deflection by an amount proportionate to the value of said resistance. A table showing what number of scale divisions correspond to different resistances is secured in the cover of the box so that in taking a reading all that need be done is to touch the cord terminals to the circuit to be tested and then read the resistance by reference to the table. As the maximum current that can be drawn from the battery is the small amount required by the voltmeter, it may be expected to last for long periods without requiring attention. The rheostat is made adjustable from the outside by means of a screwdriver so that even after the battery voltage has fallen off the instrument can still be made to give full deflection on a short circuit. The testers are made in two ranges, one giving a readable deflection through 5000 ohms maximum and the other through 25,000 ohms maximum. Machado & Roller, New York, are the selling agents.

FIG. 6.—LINEMAN'S TEST SET.

AUTOMATIC STARTER FOR INDUCTION MOTORS.

Fig. 7 herewith illustrates one of the several types of automatic starters and speed controllers for induction motors recently brought out by the American Electric & Controller Company, of New York City. The starter, which is intended for motors of the squirrel cage type, includes an auto-transformer, not shown, which may be mounted at the back of the panel or located in any other convenient place. The illustration shows the apparatus set to the "on" position for the motor running. A float-switch as shown in the upper left hand corner, a thermostat having electrical contacts or any suitable device acts at the proper time through a small relay at the right of the large upper solenoid, trips a latch and causes the main switch to open at the same time, leaving the circuits ready for starting again. To start the motor the large upper solenoid is first energized; this lifts the plunger and rod, and the latter throws the auto-transformer switch, at the same time cutting off the current in the solenoid, thus allowing the plunger to fall against the retardation of the dash-pot. The transformer switch in the meantime remains closed long enough to permit the motor to reach full speed. The plunger has by this time fallen to its lowest point, and made the connection which energizes the lower solenoid and closes the main switch across the line, throwing out the transformer switch by the same movement, thus completing the cycle. The starter for the slip-ring type of motor is similar in principle, but the plunger of the large upper solenoid carries a cross arm which makes sliding contact with a straight line set of contacts connected to grid resistance in the circuit of the motor secondary. The lower

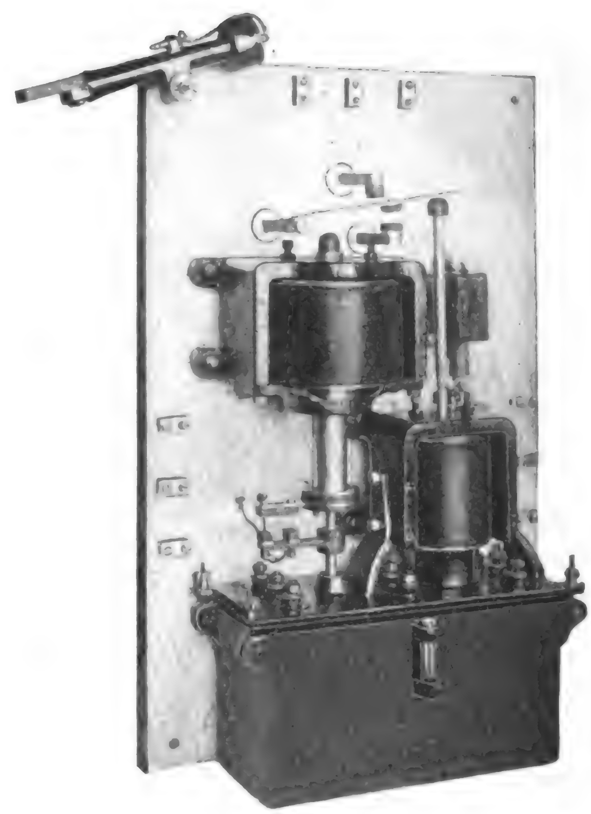

FIG. 7.—AUTOMATIC STARTER FOR INDUCTION MOTORS.

solenoid shown in Fig. 7 is dispensed with altogether. A device may be added to the slip-ring type of resistance starter, making it possible to hold the cross arm and plunger at any desired point along the row of contacts, thus making it serve as an automatic speed regulator as well as starter.

CRESCENT IMPROVED SWITCH.

The Crescent Electrical Manufacturing Company, of Rochester, N. Y., has brought out the improved switch shown by Fig. 8 herewith. The manufacturer calls particular attention to the method of fastening the fibre to the blades, which has been a weak point in many switches. The use of a notch to hold the head of a screw is done away with and a very rigid fastening is made by the use of a hooked form of screw which ensures a permanent connection, it is claimed, at all times. A detail view of this method of attaching the fibre to the blades is shown in the upper corner of the engraving.

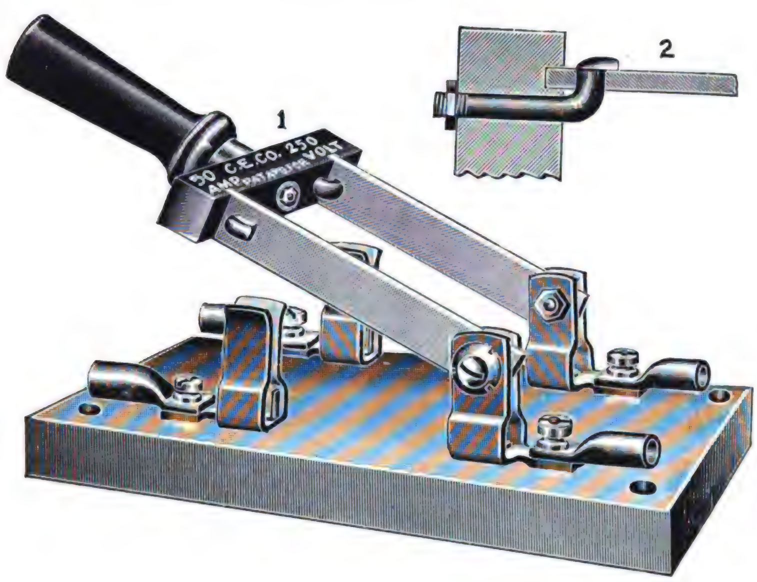

FIG. 8.—CRESCENT KNIFE SWITCH.

NEW ENTRANCE BOX.

The National Board of Fire Underwriters require that at all points where service wires enter a building, at the nearest point practicable a service switch must be installed. This service switch must also be mounted in an iron-clad box, and where the wires are run open or in moulding, they must pass through porcelain-bushed holes in the box. If conduit is used, the box must be suitably arranged for the conduit. The Troy Electrical Company, of Troy, N. Y., has brought out an entrance box consisting of two castings, the cover being nearly as deep as the box itself so as to allow the face of the switch to come nearly flush with the sides of the box. The box is 7½ in. long, 4⅜ in. wide and 4½ in. deep outside. The total length over screw ears is 9¼ in. Mounted in the box is a standard 25-ampere, 110-volt knife switch in combination with a fuse plug cut-out. The boxes are also made a little larger for 220-volt service and for three-wire systems.

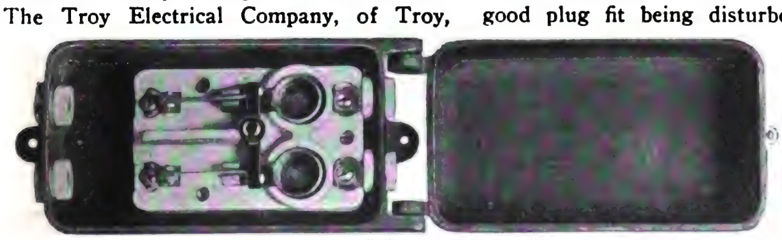

FIG. 9.—TROY ENTRANCE BOX.

NEW DECADE RESISTANCE BOX.

The Leeds & Northrup Co., of Philadelphia, Pa., has brought out a new line of Wheatstone bridges and resistance boxes of the "Decade" type, one of which is illustrated herewith. The illustration shows a resistance box having four rows of resistances ranging from one ohm to ten thousand ohms in the rheostat, and with six resistances in the bridge, all of which may be used in either arm. The advantages claimed for the "decade" plan of connecting the coils in the rheostat over that of the regular "post-office" or other plug-out methods are as follows: Each decade requires but a single plug which is never out of use, as it is either in the zero position or set on some value. It is consequently not easily lost by being laid aside. Since each decade requires but one plug, the values can be read directly from the position of the plug without the mental process of adding up a series of values as in other plans of connections. No block in the rheostat has a plug fitted to two sides of it. This prevents the possibility of a good plug fit being disturbed by the removal of a plug from the other side of the block, which is of advantage in insuring good contacts and accuracy. In this line of boxes, there is a unique arrangement of the bridge arms, which minimizes errors due to contacts and facilitates interchanging the arms. Any one of the coils in the bridge may be connected to either bridge arm, and the bridge can consequently be reversed and the coils interchanged very simply and easily. The resistances are made of wire which has an exceedingly low temperature coefficient and requires no correction at all for accuracies of 1/10 of 1 per cent. for all ordinary changes of temperature. The wire has also a negligible thermo-electric force against copper, and consequently no corrections have to be made in using it. An unusual thickness is given to the hard rubber top for this class of apparatus, in order to prevent the possibility of buckling and to insure continued good plug fits.

FIG. 10.—"DECADE" RESISTANCE BOX.

A NEW TYPE OF WATER TUBE CLEANER.

The "Demon" water tube cleaner illustrated by Fig. 11 herewith, consists essentially of two parts, viz., a scale cutting tool and a motor to drive this cutter. The motor belongs to the general class of rotary engines, but differs from most of these in the essential feature, that it has a central shaft and is free from all valves. The cleaner is designed to operate by water, and the exhaust water is used for washing away the loosened scale. The inlet and exhaust water is taken care of by properly arranged ports. The pistons of the motor, which are three in number, are attached to the shaft, and each in turn automatically projects across the cylinder, thus forming a partition between the inlet and the exhaust ports, which the water must push forward before reaching the exhaust ports. As no water can reach the exhaust until the piston has passed the exhaust ports, the water consumed is directly proportional to the speed at which the machine is revolving. A num-

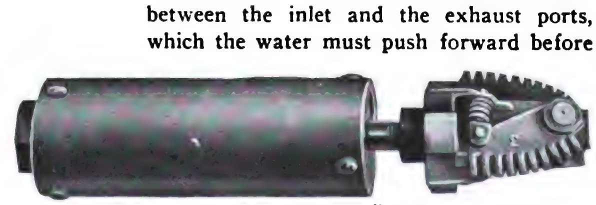

FIG. 11.—"DEMON" TUBE CLEANER.

ber of advantages are claimed for this tool by the manufacturers, one of the most important of which is the great amount of power developed. Another important advantage claimed for this machine is that a form of cutter can be used entirely different from anything else designed for this work. The cutting tool in this machine is designed to cut the scale, in contradistinction to grinding the scale. Three cutters with tooth-like edges are attached to a heavy head, the latter being directly attached to the shaft of the cleaner. These cutters are journaled to the head at the front ends, and slide in grooves at their rear end. They are not thrown out by the centrifugal force, but are forced out by powerful springs, so that they engage the scale in a positive manner. In order to prevent any possible injury to the tubes, and also to relieve the cutters of any friction and wear after the scale has been removed, the outward movement of the cutters is limited by properly arranged stops. The motor or body of the cleaner is centered in the tube by six centering lugs. The journals of the shaft are so constructed that no lubrication is necessary. All wearing surfaces are made as large as possible and of hardened tool steel. This device is manufactured by The General Specialty Company, of Buffalo, N. Y.

FIG. 12.

FIG. 13.

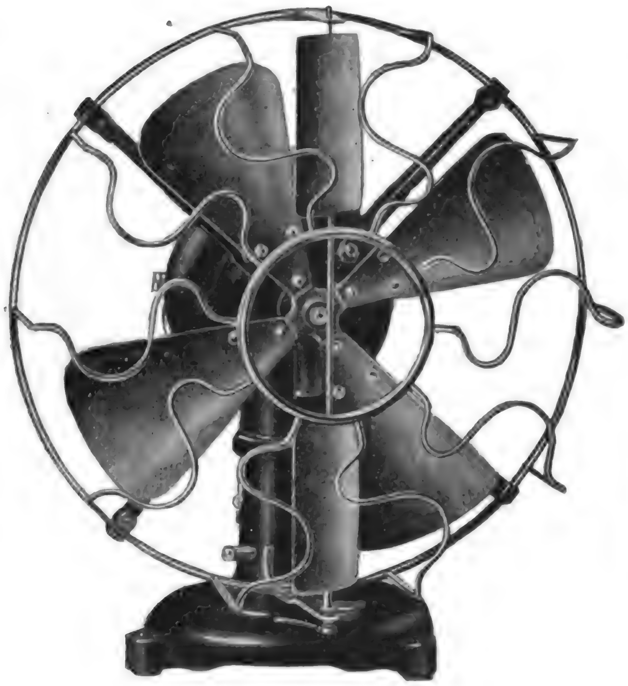

FIG. 14.—COLONIAL OSCILLATING FAN.

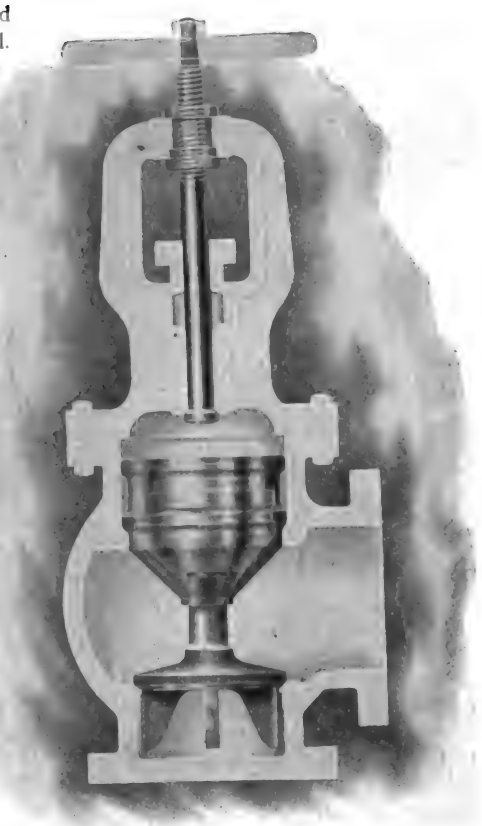

FIG. 15.—CUSHIONED NON-RETURN VALVE.

NEW TAP JOINT.

Dossert & Co., of New York City, have brought out the tap joint illustrated by Figs. 12 and 13 herewith. The assembly of the joint is shown in Fig. 13 and Fig. 12 shows the various parts. The illustrations show at a glance the entire construction. A cast copper hook machined to fit the cable forms the main member of the joint. The shank of this hook is threaded and drilled so as to form a nipple for the standard Dossert joint of the desired size. Upon this shank is secured also a compression nut, which presses upon a suitably shaped casting fitting in the space between the cable and the base of the hook, and forcing it against the cable with a great pressure. The contact area of the hook contact is a machined surface of many times the area of the cable that it surrounds, the portions being adjusted to fit the size of the tap, and in mechanical strength and electrical conductivity, the tap joint is superior to the tap wire, which it serves to connect. The application of the joint is simple. The tap wire may be fastened to the hook by the regulation Dossert coupler provided for that purpose. The main cable is then bared exactly the width of the hook and scraped. The hook is fastened over the wire and the lower casting is slipped in place. The tightening of the compression nut finishes the work, which may then be taped up and will be found to be less bulky and more conducting than any equivalent soldered joint.

COLONIAL OSCILLATING FAN.

The Colonial Fan & Motor Company, of Warren, Ohio, has brought out the oscillating fan-motor outfit shown by Fig. 14. A blade or vane located just inside the fan guard controls the oscillating movement. Collector rings and brushes placed above the switch in the base of the fan make it possible to discard the customary flexible lead connections used in some early makes of oscillators. The deflecting vane is devoid of any freak attachments. The motor travels on tempered ball bearings. The motors are made for 110 and 220-volt circuits and have fans 12 and 16 ins. in diameter. The full speeds are 1650 and 1350 r.p.m. The current consumption is said to be 55 and 77 watts.

ANDERSON CUSHIONED NON-RETURN VALVE.

Fig. 15 herewith shows the Anderson cushioned non-return valve made by the Golden-Anderson Valve Specialty Co., of Pittsburg, Pa. The valves are made in either the angle or globe pattern, and when placed between the boiler and header are claimed to equalize the pressure between the different units of a battery of boilers, as they remain closed as long as the boiler pressure is lower than that of the header. When the boiler pressure equals the header pressure, the valve opens and will remain in that position without chattering or hammering. The valves, the manufacturer claims, will automatically cut off a boiler in case of accident, and will also act as a safety stop. The illustration shows plainly the dash-pot arrangement for cushioning these valves, which is necessary in order to avoid the chattering and hammering common to this class of valve. The valves are adapted for service with superheated steam.

THE STANDARD DESK OR BRACKET FAN MOTORS.

Fig. 16 herewith shows the 1905 model of the Standard desk fan motor made by The Robbins & Myers Co., of Springfield, Ohio. The design combines in a single structure the desirable features of both the desk and bracket fans. The direction of the air current may be adjusted as desired in either a vertical or horizontal plane by means of thumb screws provided for the purpose, so that no tools are required to attain this result. Fans 12 in. and 16 in. in diameter are provided and the motors are built for 110, 220 and 250-volt, direct-current circuits. The amperes required at full speeds at these voltages with a 12-in. fan are 0.45, 0.23 and 0.23 respectively, while with the 16-in. fans the current consumption is 0.65, 0.33 and 0.33 amperes. A three-

speed regulator is provided in the base of the fan, giving speeds approximately as fol-

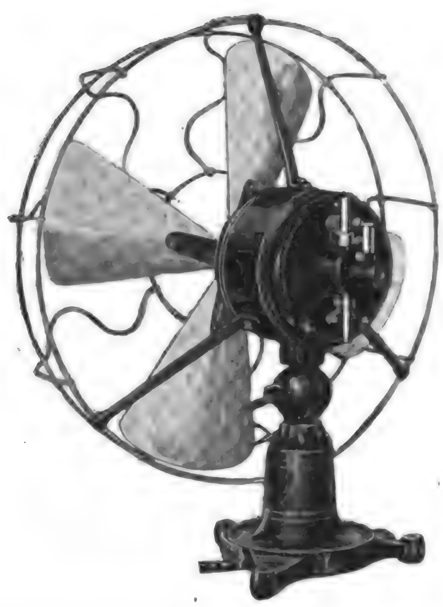

FIG. 16.—THE STANDARD FAN MOTOR

ows: 1,700, 1,300 and 1,000 r.pm. with 12-in. fans and 1,400, 1,100 and 800 r.p.m. with 16-in. fans.

CORNWELL SWITCH BOX.

The R. M. Cornwell Co., of Syracuse, N. Y., has brought out a universal switch box which can be used for either new or old work, where concealed wiring is used. It is

FIG. 17.—SWITCH BOX.

made in two general styles. The first is not made for any special switch, but will fit all standard flush rotary switches, round or square base. The second can be readily applied to all standard push button, flush receptacle or rectangular rotary switches. The boxes may be directly attached to the wood work and are properly drilled and tapped. They are made of cast iron with the required number of holes in the back for wires to enter. The dimensions are 2 3/16 by 3¾ in., and 2¼ by 4 in., with two, three and four holes.

WEINLAND MECHANICAL BOILER-TUBE CLEANER.

The accompanying illustration shows the Weinland mechanical boiler-tube cleaner made by the Lagonda Manufacturing Company, of Springfield, Ohio, at work on a boiler in the large plant of the Colorado Fuel & Iron Company, at Pueblo, Colo. The machine is attached to the boiler front and is driven by a belt from the motor which passes over pulleys on the end of a board attached to the machine at the boiler front. The pulleys on this board are loose and the board itself swings freely from the machine so that it can be moved in any position or at any angle. By this means only one setting of the motor is required. A simple arrangement of block and tackle is attached to the end of the board opposite the motor, and this can be drawn tight so as to hold the board firmly while the machine is in operation; and when moving from one tube to another, the proper slack of belt can be provided. The man at the handle directs the shaft, to the opposite end of which the cutter head is attached, as it cuts its way through the scale in the tube. The motor drives the cutter very rapidly so

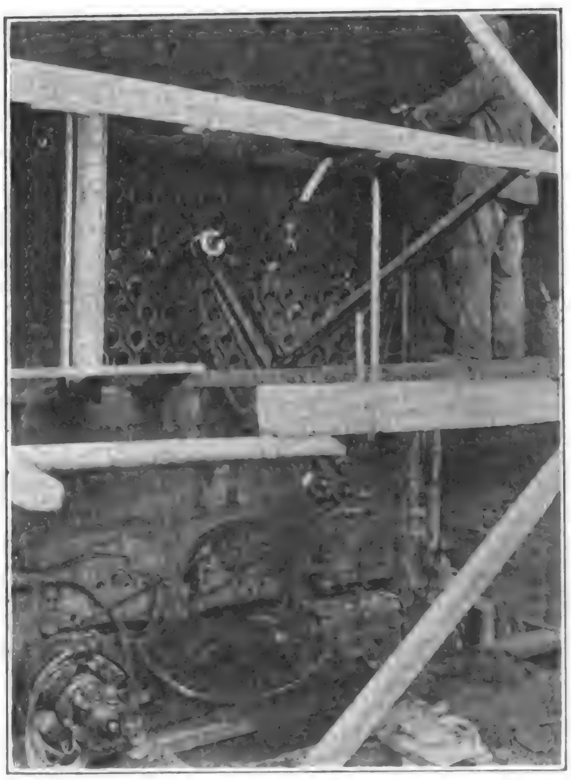

FIG. 18.—WEINLAND TUBE CLEANER IN OPERATION.

that the work is quickly performed and, it is claimed, without injury to the tube.

THE JOHNS-MANVILLE COMPANY AT THE RAILWAY CONGRESS.

The H. W. Johns-Manville Co. had an extremely interesting display of asbestos and magnesia products and electrical specialties at the exhibition in connection with the International Railway Congress held at Washington, D. C., last month. The company was represented by Messrs. T. F. Manville, president; J. E. Meek, who was in charge of the exhibit; L. B. Melville, and James Younglove, manager of the Chicago office. The exhibit attracted a great deal of attention from those at the Congress and elicited unqualified commendation.

STANLEY-G. I. CONSOLIDATION.

The Stanley Electric Manufacturing Company, Pittsfield, Mass., and the General Incandescent Arc Light Company, of New York, have consolidated; the corporate title of the combined interest will be Stanley-G. I. Electric Manufacturing Company. The Stanley Co. as engineers and manufacturers of the well-known S. K. C. system acquired an enviable reputation, and the General Incandescent Arc Light Company is widely recognized as a builder of high-grade arc lamps, alternating and direct-current motors and electrical specialties. The combination is a peculiarly happy one. The officers are William Murray Crane, president; C. C. Chesney, first vice-president; M. D. Barr, second vice-president; M. J. Insull, third vice-president.

DOBLE WHEELS TO BE BUILT IN CANADA.

The Abner Doble Co., of San Francisco, announces that arrangements have been made with the John McDougall Caledonian Iron Works Company, Limited, of Montreal, Canada, whereby the latter becomes sole licensee for the manufacture of the Doble water wheels in the Dominion of Canada. The tangential water wheels and needle regulating nozzles manufactured by the Abner Doble Co. are well known for their excellence of design and workmanship, and considerable engineering interest has recently been shown in relation to the four 8000-h.p. wheels which that company built for operation in California power plants.

The McDougall Co. is said to have the most extensive machine works in Canada, its plant including machine shops, a pattern shop, a foundry, forging works and a structural material shop. The plant is therefore well equipped for the manufacture of water wheels and other hydraulic machinery. They already have in hand the building of a 100-h.p. wheel to operate under a 170-ft. head, taking water through a 3½-in. jet and having a speed of 130 r.p.m.

NEW BOOKS.

THE INDICATOR HANDBOOK, PART II. (Second Edition.) By Charles N. Pickworth. New York: D. Van Nostrand Company. Buckram. 130 pages, 5 inches x 7½ inches; 150 illustrations and several tables. Price, $1.50.

Those interested in the use of steam indicators are doubtless familiar with the previous edition of this little book, as well as its mate, Part I. The present edition has not been changed greatly; the few errors in the 1902 edition have been eliminated and an illustrated description of the Mathot explosion and pressure indicator for gas engines has been added. The author still retains his preference for terminal pressure factors based on the theory that saturated steam expands according to Rankine's law for superheated steam, and disdains to in-

sert a table of mean effective pressure factors for different ratios of expansion. It is unnecessary to say that in other respects the book leaves practically nothing to be desired.

TESTING OF CONTINUOUS-CURRENT MACHINES. By Charles Kinzbrunner. New York: John Wiley & Sons. Buckram; 326 + x pages, 5½ in. x 8½ in.; 249 illustrations. Price, $2.00.

This is intended as a practical handbook for engineers as well as a textbook for advanced students, and it is very well written and arranged. The section describing various instruments, switches, etc., might as well have been omitted, being unnecessary to the class of readers who are far enough advanced to profit by the remainder of the book. The discussion of armature resistance and its measurement is excellent and unusual. The exposition of the so-called "indirect method" of testing efficiencies is not sufficiently clear to be of benefit to anyone not already familiar with it or without enough experience to analyze it independently of the author's effort to explain it. In other respects the book corresponds very closely to the other high-grade works of the same general scope which have been published.

ALTERNATING-CURRENT MACHINERY. By William Esty, S.B., M.A. Chicago: American School of Correspondence. Cloth; 420 pages, 6½ in. x 9½ in.; 380 illustrations. Price, $3.75.

This is far and away the best literary production from the American School of Correspondence that has thus far come to the reviewer's notice. The author describes briefly the fundamentals of alternating-current generators of the standard types, the synchronous motors, the rotary converter, the induction motor, the transformer, and all of the usual instruments; there is also a section devoted to switchboards and appliances, which includes special apparatus such as synchronizers, inductive regulators, motor-operated switches, etc. The principles of each class of apparatus are thoroughly explained and their application in practical work is also discussed as fully as space considerations will allow. While there are some irrelevant half-tone engravings interspersed with the germane illustrations, the proportion of these is conspicuously smaller than in previous publications of the same establishment. Taken as a whole, this book is highly commendable to electrical students of all grades, not excepting those already in graduating classes, to whom it will undoubtedly be useful as a reference book.

THE THEORY OF THE LEAD ACCUMULATOR (STORAGE BATTERY). By Friedrich Dolezalek. Translated by Carl L. von Ende. First edition. New York: John Wiley & Sons. 1904. Cloth; 241 + xi pages; 7¼ inches by 4¾ inches; 30 illustrations. Price, $2.50.

This is an excellent exposition of the subject. Since the translation of Reynier until this work appeared there has been no book published in the English language that presented the theory of the lead accumulator in a satisfactory manner. Reynier discussed all types of accumulators that, up to that time, had had any industrial application, while the present work is confined to the lead cell. This is, to some extent, an index of the manner in which the accumulator was then and is now regarded by the electrical public. When Reynier's book was written, there were strong hopes of the ultimate success of several types of accumulators; at the present time, the lead accumulator is the only one of any commercial importance.

The subject is treated in a systematic manner, although the headings of the chapters, in some instances, are a little misleading. For example, the first chapter is headed "Chemical Theory of Origin of Current," which is unobjectionable, but the second chapter is headed "Thermodynamical Theory of Origin of Current," as though this were a rival theory; whereas, the thermodynamic theory does not, strictly speaking, account for the origin of the current, but of the electromotive force; that is, the question whether or not an electric current will be produced, in given circumstances, is not determined by the thermodynamic theory but, given a current due to any particular chemical reaction, the thermodynamic theory will account for all the energy changes and, hence, the electromotive force. The third chapter is headed "Osmotic Theory of the Origin of the Current"; another theory which, according to its votaries, is not opposed to the thermodynamic theory, but supplements it. An enumeration of some of the other chapter headings will give an idea of the scope of the book: "Variation of Electromotive Force with Acid Concentration," "Variation of Electrode Potential with Acid Concentration," "Temperature Coefficient," "Influence of External Pressure," "Behavior During Charging and Discharging," "Reversability," "Changes in the Open Cell," "Internal Resistance," "Capacity," "Degree of Efficiency and Working Efficiency," "Changes in the Cell During Formation," "Methods of Measurement," "Table of Density and Percentage Strength of Mixtures of Sulphuric Acid and Water." This table is made on a somewhat different plan from the sulphuric acid tables usually found in chemistries and works on the storage battery, giving 0.001 parts acid at specific gravity 1. This is due, apparently, to the fact that the gravity of the acid is given for a temperature of 15° C., while the standard is water at 4° C.

In discussing the measurement of internal resistance, the author says "the method still in use of getting at the internal resistance from the difference of potential between the cell in open and closed circuit is quite as full of error, because the polarization which sets in upon closing the circuit frequently exceeds the loss of potential through the internal resistance." This is so, providing the true internal resistance be required for scientific purposes; but, for engineering purposes, the quantity sought is usually that which may be called the effective resistance, being of more engineering importance than the true resistance.

PERSONAL.

MR. J. T. BAKER has been appointed district manager of the Aurora (Ill.) Division of the Western United Gas & Electric Company.

MR. W. L. DRIESBACH, of Easton, Pa., has purchased the entire property of the Watkins (N. Y.) Gas & Electric Light Company.

MR. W. S. McGOWAN, JR., has been appointed Eastern Sales Manager of the American Brake Shoe & Foundry Company, with headquarters at 170 Broadway, New York.

MR. P. A. McCARTHY has been reappointed City Engineer by the city authorities of Lufkin, Tex., and has appointed Mr. J. P. Starns his chief deputy and Mr. Frank McCarthy, assistant deputy.

MR. LAMAR LYNDON, the well-known consulting engineer, has removed his offices from the Park Row Building to No. 80 William Street, New York. The telephone number has also been changed, from 1650 Cortlandt to 4527 John.

MR. A. P. HEAD, London representative of the Wellman-Seaver-Morgan Company, recently completed a tour around the world in the interests of his company. While on this trip Mr. Head established sub-agencies in all the principal cities of Australasia and India.

MR. ALBERT S. CRANE has been appointed chief hydraulic engineer of the J. G. White Company's staff. Mr. Crane has been actively engaged in hydraulic engineering since his graduation from Cornell University in 1891, and is widely experienced in his branch of work.

MR. W. G. SCHRON, formerly of the sales department of the Westinghouse Machine Company, has entered the service of the Allis-Chalmers Company, and will make his headquarters at the Pittsburg office and devote his attention to the sale of gas engines, steam engines and steam turbines.

MR. FRANCK Z. MAGUIRE has established offices at 10 Wall Street, New York, for the sale of American and foreign patents. Mr. Maguire is well known in his field on both sides of the Atlantic, having maintained offices in London for more than ten years and transacted business extensively in this country also.

MR. H. J. SLIFER has been appointed steam railway expert for the J. G. White Company, New York, and is now in responsible charge of all matters relating to the company's steam railway undertakings. Mr. Slifer is a graduate of the Polytechnic College of Pennsylvania, and has had extensive and diversified experience in railroad engineering, bridge construction and kindred lines.

MR. A. S. WESSLING, of the Bullock Electric Manufacturing Company's staff, recently made a tour of the principal universities and colleges where technical courses in applied mechanics are given and delivered a lecture on "Methods of Control for Variable Speed Motors," in which he made special reference to the control of machine-tool motors and described in detail the features of the Bullock multi-voltage system.

MR. FRANK C. RANDALL, previously vice-president and general manager of the National Electric Company, Milwaukee, has accepted the managership of the Allis-Chalmers Company's New York office. Mr. Randall is well known throughout electrical and street railway circles, having been active in these fields for the past ten or twelve years. Prior to his connection with the National Company he held an important position with the J. G. Brill Company.

MR. WILLIAM C. HUBBARD, for several years with the Westinghouse Electric & Manufacturing Company, has severed his connection with that company and entered the sales department of the Cooper Hewitt Electric Company, New York. Mr. Hubbard has had long experience in the lighting field. For two years he was vice-president and general manager of the Electric Arc Light Company, and afterwards New York manager for the Manhattan General Construction Company until both companies were absorbed by the Westinghouse interests.

TRADE PUBLICATIONS.

MERCURY VAPOR LAMPS.—Cooper Hewitt Electric Company, New York.—Bulletin No. 6, devoted to mercury vapor lamps for general illumination indoors.

STEAM SPECIALTIES. Golden - Anderson Valve Specialty Company, Pittsburg, Pa.—A convenient little catalogue devoted to Anderson valves and cocks and Golden tilting traps.

RECORDING THERMOMETERS. The Bristol Manufacturing Company, Waterbury, Conn.—Catalogue No. 28, in which is described the complete line of Bristol recording thermometers for all classes of service.

RAILWAY GENERATORS. Crocker-Wheeler Company, Ampere, N. J.—This is Bulletin No. 52, superseding No. 26 and devoted to an illustrated description of large direct-current railway generators.

CONSTANT-SPEED DYNAMOS AND MOTORS. Electro-Dynamic Company, Bayonne, N. J.—This is Circular No. 11 in which are briefly described Types L and S direct-current dynamos and constant-speed motors.

DIRECT-CONNECTED STEAM ENGINES. Chandler & Taylor Company, Indianapolis, Ind.—This is Bulletin No. E-101, devoted to "Class 1425" enclosed automatic engines for direct connection to electric generators.

SHAWMUT CONDUIT OUTLET BUSHING. Chase-Shawmut Company, Newburyport, Mass.—Bulletin No. 31, in which are convincingly presented the advantages of the new outlet bushing manufactured by this company under the Erickson patent.

MOTOR - DRIVEN PROPELLER FANS. Crocker-Wheeler Company, Ampere, N. J.—This is Bulletin 54, and it contains illustrations and a short description of Crocker-Wheeler motors as applied to the driving of Davidson propeller-type ventilating fans.

WATER POWER EQUIPMENT. The Wellman-Seaver-Morgan Company, Cleveland, Ohio.—This is a handsome publication of standard catalogue size containing illustrated descriptions of the Jolly-McCormick turbines built for relatively low heads.

DIRECT - CURRENT SWITCHBOARD PANELS. General Electric Company.—Bulletin No. 4408, containing an illustrated description of a new line of "double-pole" direct-current switchboard panels for use in conjunction with generators and rotary converters (direct-current side, of course).

ROLFE ELECTRICAL SPECIALTIES. Rolfe Electric Company, Rochester, N. Y.—A book of vest-pocket size containing illustrated descriptions of some of the specialties manufactured by this company and a presentation of the fundamental electric laws and definitions of the principal terms used in electric practice.

MONARCH ENGINE-STOP AND SPEED-LIMIT SYSTEM.—The Consolidated Engine Stop Company, New York.—This is an attractively executed booklet containing an illustrated description of the Monarch system, some strong arguments concerning it and a partial list of satisfied users.

BIJUR STORAGE BATTERY. General Storage Battery Company, New York.—Catalogue "A," of standard size, containing a profusely illustrated description of the high-duty storage cell described in this paper last month. The catalogue is well executed and the contents are unusually well arranged from the standpoint of the user.

HIGH TENSION TROLLEY LINE CONSTRUCTION. Westinghouse Electric & Manufacturing Company.—Circular No. 1110 containing a liberally-illustrated description of the Westinghouse catenary line construction employed for high-tension alternating-current trolley lines in conjunction with the company's single-phase railway system.

LIGHTING OF HOTELS AND CLUBS. Holophane Glass Company, New York.—This is a companion book to the artistic productions noticed in this department of previous issues and is fully up to the standard set in the preceding publications. The book is profusely illustrated and the arguments in favor of Holophane glass are well supported.

EXPERIMENTAL DYNAMOS AND MOTORS AND CASTINGS. Parsell & Weed, New York.—Bulletin 9051, containing an illustrated description of a small Brocksmith dynamo or motor which is built in several styles and furnished either complete or partly finished and singly or in motor-generator style. The castings alone are also supplied to those wishing to do their own machine work and assembling.

FAN-MOTORS. The Emerson Electric Manufacturing Company, St. Louis, Mo.—Catalogue No. 4050, containing illustrations and specifications of a new line of direct-current desk and bracket fan-motors brought out this year. These machines are somewhat similar in appearance to the well-known alternating-current motors built by this company, but differ considerably in constructional details. They are built in conventional sizes.

STEAM BOILERS, HEATERS AND ENGINES. The Brownell Company, Dayton, Ohio.—Catalogue No. 54, of standard size, devoted to the well-known Brownell engines, boilers and feed-water heaters. The engines are automatic and of the side crank type, mostly self-contained; the boilers are built in both vertical and horizontal types, and the heaters in both the open and closed types. The book is well executed and attractive in appearance.

BUSINESS NEWS.

THE WESTINGHOUSE MACHINE COMPANY has opened new branch offices at Atlanta, Ga., Charlotte, N. C., Cincinnati, Denver and San Francisco.

G. M. GEST, New York, has been awarded the contract for a complete underground conduit system for the Consolidated Electric Light Company, Portland, Me.

THE AMERICAN ELECTRIC & CONTROLLER COMPANY, New York, has removed its headquarters from 12 Dey Street to the Electrical Exchange Building, 136 Liberty Street.

L. E. JEANNIN informs us that he has established his electrical supply business at Ottumwa, Iowa, and not at Orlando, Fla., as stated in this column last month.

THE KEYSTONE LUBRICATING COMPANY, Philadelphia, has established an office at 253 Broadway, New York, in charge of Mr. W. F. Bilyeu, who will be glad to discuss with interested persons the merits of Keystone grease.

LOCKE INSULATOR MANUFACTURING COMPANY, Victor, N. Y., has broken ground for a two-story addition to its factory plant, the new building to cover an area 50x150 feet. The company is also erecting two large porcelain kilns.

THE REEVES ENGINE COMPANY, Trenton, N. J., has removed its Chicago office from the Monadnock Building to the Ellsworth Building, 355 Dearborn Street. The telephone number has not been changed.

EUGENE MUNSELL & CO., and the MICA INSULATOR COMPANY, New York, are sending out to the trade an attractive blotter printed in two colors and announcing the removal of their Chicago offices from 117 Lake Street to 358 Dearborn Street.

THE UNDERFEED STOKER COMPANY, Chicago, wishes to call attention of Electric Light Convention delegates to its Denver sales agency, in charge of Gilbert Wilkes & Co., 435 Seventeenth Street, where visitors will be welcome at all times.

THE TRUMP MANUFACTURING COMPANY, Springfield, Ohio, reports a good demand for its well-known turbines in the electrical and railway field. A railway company in central New York has just ordered a pair of the largest size of Trump horizontal wheels for power-station work.

WILMINGTON FIBRE SPECIALTY COMPANY, Wilmington, Del., has brought out a very complete line of hard fibre cleats for electric wires. Among the advantages embodied in this line are the recognized superiority of fibre over wood in toughness, absence of grain and lower degree of inflammability.

H. W. JOHNS-MANVILLE COMPANY, New York, has found it absolutely necessary to establish more branch offices in order to facilitate the handling of its business and promote the convenience of its customers. Branches have therefore been established at San Francisco, Seattle, Los Angeles, Kansas City, Little Rock and Minneapolis.

MISSOURI AMERICAN ELECTRIC COMPANY, St. Louis, Mo., has brought out a new incandescent lamp the principal feature of which is the method of sealing the tip; instead of leaving a sharp projecting point, as in the usual type, the tip is sunk flush with the contour of the bulb. The construction and its advantages can better be appreciated by inspection.

THE CANADIAN WESTINGHOUSE COMPANY, LTD., reports among recent sales that of a 200-kw. railway generator and a number of car motors to the Edmonton Street Railway Company; also the sale of a 500-kw. turbine-generator to the Canadian Pacific Railway Company, to be installed at Fort William for the purpose of supplying power to various grain elevators there. The unit is to deliver three-phase currents at 600 volts and 30 cycles.

WAGNER ELECTRICAL MANUFACTURING COMPANY, St. Louis, Mo., has opened a branch office at San Francisco, in the Rialto Building, and will hereafter transact all of its Pacific Coast business through its local manager, Mr. A. J. Myers, who has been identified with the company's interests in that section for the past ten years. Sub-branches will soon be established at Los Angeles and Seattle.

THE LOWE ELECTRIC COMPANY has been organized by Mr. Ernest A. Lowe, formerly of the firm of Lowe & Leveridge, and its general office is located at 35 Dey Street, New York. The new company has taken over the manufacturing plant and business of Robert L. Hailey, and Mr. Hailey is a stockholder and the secretary of the company. The company will conduct a general electrical supply business and a repairing and manufacturing department, the latter being under Mr. Hailey's supervision.

WESTINGHOUSE ELECTRIC & MANUFACTURING COMPANY is not complaining of dullness in its lines. Alternating-current generators, exciters, direct-current railway generators and motors, alternating-current motors and transformers, switching apparatus, etc., have all been sold in large quantities during the past few weeks. The Wisconsin Light & Power Company recently placed with the various Westinghouse Companies orders covering the entire steam and electrical equipment of a large lighting and power plant.

SOUTHERN ELECTRICAL COMPANY, Nashville, Tenn., informs us that the growth of its business has led to a complete reorganization. The company will hereafter restrict its field to the sale of apparatus and supplies and discontinue contract work entirely. Mr. Oscar C. Turner, for a long time connected with the Western Electric Company, has taken an interest in the Southern Company and becomes its vice-president and manager. Mr. Felix Shwab remains president and Mr. Wm. M. Bowles, secretary.

ALLIS-CHALMERS COMPANY, Milwaukee, reports a continuance of brisk trade in its manifold lines. A large contract was recently closed for electric apparatus for an extensive increase in the power-house equipment of the San Joaquin Power Company, Fresno, Calif., the additional machinery aggregating 3000 horse-power. The Tuolume Electric Company, San Jose, Calif., has also ordered a large quantity of additional machinery in the way of alternating-current generators, transformers, etc., and other large contracts for equipment of the same general class are in hand. A large number of sales of smaller machinery and accessory apparatus is also reported.

CENTRAL STATION NEWS

Readers are cordially invited to contribute to this department items of news relating to plants in their vicinity.

ALABAMA.

BIRMINGHAM.—The Brighton Waterworks & Power Company has been incorporated, with a capital of $10,000.

CARBONHILL.—It is proposed to construct water works and an electric light plant at a cost of $25,000 to $35,000. No engineer has been selected as yet. J. S. Shannon is chairman of the Light Committee.

TUSCUMBIA.—The Mussel Shoal Electric Company has been organized with a capital of $10,000 for the purpose of supplying electric light and power, heat, etc., from Mussel Shoals. The incorporators are Thos. H. Jackson, Memphis, Tenn., Jas. Jackson, of Tuscumbia, and others.

MONTGOMERY.—The Montgomery Light & Water Power Company has changed hands. Mr. W. F. Vandiver as president has sold his holdings in said company to Mr. McMillan, of New York. The company will shortly be reorganized. The company furnishes lights to the city of Montgomery and electric power to each of the two electric railway companies of this city.

ALASKA.

NOME.—Thaddeus Avery, Jr., chief engineer of the Sawtooth Electric Power Company, was married April 12 at San Francisco to Miss Stella E. Morse.

ARIZONA.

WINSLOW.—The Winslow Electric Light & Power Company has petitioned the Council for a franchise for transmitting electrical power for lighting purposes.

ARKANSAS.

YELLVILLE.—Isaac Emery has petitioned the Council for a franchise for the establishment and maintenance of an electric light plant.

PRAIRIE GROVE.—A franchise has been granted to C. L. Cummings for an electric light plant. Immediately after the publication of the ordinance the necessary machinery will be bought, and as the power will be furnished by the Prairie Grove Milling Company's engine, the installation of the dynamo and the necessary wiring are all that is to be done.

LITTLE ROCK.—Articles of incorporation were filed recently by the Merchants' Investment Company of Little Rock, the purpose of which is to promote, construct, own and operate electric light and power plants for the production, generation and furnishing of electric supplies, light, heat and power, and selling the same to consumers. The officers are: C. J. Kramer, president; Wm. S. Mitchell, vice-president; J. B. Wishendorff, secretary; Harry Lasker, treasurer. The directors are: S. J. Beauchamp, Harry Lasker, P. J. O'Brien, Albert Pfeifer, G. H. Bowser, Albert D. Cohn, T. B. Martin, Jr., J. J. Mandlebaum, Wm. Bracy and Wm. S. Mitchell. The capital stock is $250,000, of which $56,000 has been subscribed, and is divided into 10,000 shares of the value of $25 each. It is understood that the company will immediately start the erection of its plant in this city.

CALIFORNIA.

VISALIA.—It is stated that bids will be received until June 5 for an electric franchise in the city. Eugene L. Scott, County Clerk.

ANAHEIM.—The Board of City Trustees has authorized Engineer A. L. Lewis to prepare a report on the extension of the electric light plant and an increase of the water supply.

WHITTIER. — The Edison Electric Company will rebuild its distributing system at this point. The changes to be made at the central station will double the capacity of the present system.

SANTA BARBARA.—The Edison Company will establish a 1,500-h.p. motor generator at its local plant, and is to run a line shortly from the immense Kern River plant to Santa Barbara.

MADERA.—A Merced company is desirous of furnishing electric light and power to Madera, and will invest a capital of $100,000. The proposition has been brought to the notice of the Madera Board of Trade.

LOS ANGELES.—The San Joaquin Light & Power Company, recently organized, has filed articles of incorporation, showing a capital stock of $8,000,000. W. G. Kerekhoff and A. C. Balch are among the incorporators of the new concern.

SAN DIEGO.—The San Diego Consolidated Gas & Electric Company is about to absorb the San Diego Gas & Electric Light Company of this city. A large amount of new capital will be expended by the new company in the way of extensions to the existing plant.

SANTA BARBARA.—The Merchants Mutual Electric Light Company, which is being formed by merchants of Santa Barbara in opposition to the Edison Electric Company, is now ready to commence the construction of its plant at Santa Barbara.

SAN JOSE.—Mr. Chester H. Pennoyer, who recently resigned from the service of the California Gas & Electric Corporation as manager of its united gas and electric system in this city, has taken the management of the Pacific Coast office of the National Conduit & Cable Company, San Francisco.

ANGELS.—R. E. Starkweather and C. E. Wishon of the California Gas & Electric Company have been at Angels recently, planning an extension of the Standard Company's electric line through Calaveras, Tuolumne and Merced Counties to furnish power to the mines and lights for the mining belt.

EUREKA.—The survey of the pole line from Eureka to Loleta for the North Mountain Power Company has been completed, and it is understood that actual construction work will be rushed rapidly forward. A sub-station is to be established at Loleta and the Fortuna Lighting Company will tap the line at that point.

STOCKTON.—Leopold Wallach, of New York, has placed a $5,000,000 bond issue for the Stanislaus Electric Power Company. The company is to build a power plant at Murphys and supply energy to Stockton, San Jose and San Francisco. It will generate, if necessary, 24,000 horse-power for light and power purposes. Work on the new plant has commenced.

SEBASTOPOL.—Sealed bids will be received by Wm. T. Searles, town clerk of Sebastopol, June 6, for a franchise to construct and operate poles, wires, transformers and other conductors for the transmission of electricity for electric light and power purposes and to operate electric light and power system there, as applied for by the Sebastopol Light, Power & Water Company.

SAN FRANCISCO.—At the recent annual meeting of the stockholders of the American River Electric Company, held in San Francisco, plans were discussed for extending the company's electric transmission system, operating from the power house near Placerville, to Stockton ,Cal., and intermediate points. The following directors were elected: M. Fleishhacker, F. H. Buck, H. Fleishhacker, W. Bell, A. Anderson, W. E. Gerber and S. C. Scheeline.

SAN FRANCISCO.—Articles of incorporation of the Loon Lake Water & Power Company (successor to the California Water & Mining Company) have been filed with the County Clerk. The company is incorporated for $200,000, with $500 worth of stock subscribed. The officers of the new company are Cleaveland B. Forbes, president; C. M. Fitzgerald, vice-president and general manager; Stanley Forbes, treasurer. The company's principal place of business is in San Francisco.

RENO.—The Reno Power, Light & Water Company's generating station at Reno, Nev., has met its second accident within a month. The first shutdown was attributed to obstructions getting into the pipe line and damaging the hydraulic end of the plant to the extent of several thousand dollars. A temporary supply of current for lighting was then obtained from the transmission plant of the Truckee River General Electric Company, at Floriston, Cal. The plant was started up recently, but after one day's operation broke down again from some cause. Transformers were burned out, and the damage to machinery is estimated at $7,000 this time.

SAN FRANCISCO.—At the annual meeting of the San Francisco Gas & Electric Company, the old board of directors were reelected. There was no change made in the officers of the company, who are W. B. Bowen, president; A. H. Payson, first vice-president; C. Osgood Hooker, second vice-president, and Charles L. Barrett, secretary and treasurer. By the end of the present year the concentration of nearly all of the engine-driven units in the Potrero electric power station will have been accomplished. The Jessie Street plant is being rebuilt as a model sub-station and by the middle of next year its last remaining steam engine will have been removed. About 2,000 horse-power is being purchased under contract from the Standard Electric transmission line, owned by the California Gas & Electric Corporation. The meter department is also being thoroughly overhauled. A new and more satisfactory system of testing meters on the consumers' premises has been inaugurated and a number of additional inspectors have been added.

COLORADO.

SALIDA.—Reports state that the Edison Electric Light Company and the Salida Light, Power & Utility Company, both of this city, have been consolidated and the two plants will be combined at an early date.

PUEBLO.—Mr. A. W. Linn has esigned his position as superintendent of motive power for the Pueblo Light & Power Company, which is controlled by the Pueblo Suburban Traction & Lighting Company, to accept the position of general manager of the street car system of Seattle, Wash.

CONNECTICUT.

HARTFORD.—The Hartford Electric Light Company has been authorized to issue bonds to the amount of $2,000,000, and to increase its capital from $1,600,000 to $3,000,000.

WILLIMANTIC.—Mr. Arthur E. Jackman, for some time manager of the Willimantic Gas & Electric Light Company, will locate in Boston, Mass., as manager for the Adams-Bagnall Company, of Cleveland, O. His offices will be in the Boston *Journal* Building.

DELAWARE.

WILMINGTON.—At a meeting of the stockholders of the Delaware Electric Light, Heat & Power Company the following officers were re-elected for the ensuing year: President, E. E. Neff; treasurer, M. Miller; secretary, J. G. Rosenthall; general manager, E. F. Gwynn.

DOVER.—The Consumers' Light, Heat & Power Company has been incorporated with a capital stock of $1,000,000. The incorporators are William M. Fook, of Chicago; James L. Wolcott and James H. Hughes of Delaware. The Citizens' Light, Heat & Power Company, an auxiliary concern to the above, has also been incorporated with a capital stock of $300,000.

WILMINGTON.—The Wilmington Electric Light & Power Company, which was incorporated recently at Dover, with a capital of $1,000,000, has organized by electing the following officers: President, Charles C. Kurtz; secretary, Stanley Baker; manager of the Delmarvia Telephone Co.; treasurer, Henry Baird; directors, Henry P. Scott, Horace W. Gause, Samuel K. Smith and Charles C. Kurtz of this city, and George R. Webb, of Baltimore, Mr. Webb being largely interested in

both the Maryland and Delmarvia Telephone Companies. President Kurtz is said to have stated that the company would begin to erect a power plant as soon as a franchise is secured, and it is hoped to begin business very soon. One of the chief objects of the company is to heat dwellings. It also proposes to furnish current for light and power.

FLORIDA.

EUSTIS.—Armstrong & Smith have petitioned the Council for a franchise for water works and an electric light plant.

MONTICELLO.—The Monticello Power Company has been incorporated with a capital of $10,000 to operate an electric light and power plant.

OCALA.—The Florida Power Company has been incorporated with a capital of $300,000 by W. N. Camp, R. F. Brewer, G. D. Munsing and others.

TARPON SPRINGS.—It is proposed to construct an electric light plant and ice factory, at a cost of $6,000. Address N. F. McDonald, engineer in charge.

ALACHUA.—The Alachua Ice & Water Company has been incorporated with a capital of $25,000. It will construct an electric light plant. Incorporators: R. L. Stringfellow, R. R. Livingston and others.

ST. AUGUSTINE.—At a recent meeting of the City Council a communication was received and read from Gen. J. C. R. Foster, submitting a proposition to install an electric lighting, heat and power plant in this city. It is understood that a company is being formed, which will be known as the St. Augustine Gas & Electric Light Company and that the new plant will be installed as soon as the franchise has been granted.

GEORGIA.

JACKSON.—J. B. McCrary, of Senoia, has been selected to prepare plans for water works and an electric light plant.

MONROE.—The citizens have voted to issue $15,000 bonds for an electric light plant. J. B. McCrary, of Senoia, is engineer.

OCILLA.—The City Council has decided to call an election to vote on issuing $20,000 bonds for water work and an electric light plant.

AUSTELL.—It is proposed to construct an electric light plant to cost from $2,500 to $3,000. No engineer has been selected as yet. C. J. Shelverton is Mayor.

PELHAM.—W. H. Maury, of the recently incorporated Pelham Electric Light Company, writes that he will receive bids at once for an electric light plant to cost $12,000.

TALLAPOOSA.—J. Edgar Black and J. E. Gelder are formulating plans for the erection of a new electric light plant here and are investigating the cost of a plant of sufficient size to supply a town of 2,500 population.

LOUISVILLE.—C. F. Wagoner has resigned his position as manager of the city electric light and water works plants to accept a position as first assistant mechanical engineer of the Terminal Station at Atlanta, this State.

HAWKINSVILLE.—The city of Hawkinsville has rescinded a 10-year contract offered by the Hawkinsville cotton mills to light the streets, and an election will probably be held on the question of issuing bonds for a municipal electric lighting plant.

COLUMBUS.—Developments of considerable magnitude are being projected near Columbus. H. H. Hunt and Henry G. Bradlee, of Stone & Webster, Boston, have expressed the opinion that to develop the Clapp's factory water power will soon become a necessity, this being located two miles from Columbus. The Stone & Webster people will likely develop 10,000 horse-power on the Chattahoochee River.

COVINGTON.—The City Council of Covington has approved the proposition of the White Shoals Power Company to supply electricity for lighting the municipality, the terms including the loan of $45,000 in city bonds. An election will be called to vote on this bond issue. The White Shoals Power Company will have a capital stock of $150,000, and intends to develop waterpower on the Alcovey River, ten miles southeast of Covington.

HAWAII.

HONOLULU.—The Public Works Department of this city has just completed plans and specifications for a new hydraulic-electric station in Nunann Valley. Bids on same have been advertised and the building is to be finished by the 15th of June.

HONOLULU.—Deeds have recently been recorded at Honolulu, Hawaii, by which the financing of the Kauai Electric Company will be carried out with the aid of the McBryde Sugar Company. Over $200,000 will be spent on the plant. The plantation is to pay about $36,000 per year for the power and water. The McBryde Company also pays over $150,000 of its second issue of bonds, and guarantees $150,000 of the electric company's bonds.

IDAHO.

JULIETTA.—Armstrong & Morrison have purchased the mill and electric light business of Holbrook & Son.

LEWISTON.—Francis Jenkins and associates, of Moscow, Idaho, are giving attention to plans for the establishment of a large power plant at Elk Creek Falls, where the minimum capacity is about 3,500 horse-power.

WEISER.—In regard to the construction of a power plant on Weiser River, the work is not assured yet, but it will probably be done. If the plant is constructed it will cost $50,000. Pitts, Ellis & Co. are interested in this plant. A. E. Fox is the engineer.

AMERICAN FALLS.—The new plant of the American Falls Power, Light & Water Company has been completed and is supplying electrical power to Pocatello and other points. The plant has a capacity of 2,500 horse-power, of which 1,250 is at present being utilized.

BOISE.—The Utility Power Company, Ltd., has filed articles of incorporation, with a capital of $300,000. J. L. Weaver, Frank Martin, L. J. Weaver, Henry Fitch and B. A. Dare are named as the incorporators. The company will establish plants for the generation and distribution of electricity.

BOISE.—The Western Power Company, which contemplates the installation of a 10,000-h.p. power plant, has been organized with the following officials: J. B. Coate, president; L. A. Coate, secretary and general manager; I. V. Howard, vice-president; A. J. Wilson, electrical engineer; G. R. Pritchet, Lee Bunch and C. F. Dill, directors.

PAYETTE.—The City Council has granted three franchises to William and Sinclair Mainland, Eastern capitalists, one for a gas plant, another for an electric-light plant and the third for electric railways. Work on the light plant must begin within twelve months, and cars must be running on the railways within eighteen months.

ILLINOIS.

GEORGETOWN.—The Georgetown Electric Company will expend about $15,000 in improvements.

CARLINVILLE.—C. W. Carr, of Virden, is interested in the construction of an electric light plant in Carlinville.

EDWARDSVILLE.—The Pana Electric Light plant has been sold to A. H. Bickmore & Co., the representatives of a New York syndicate.

MANSFIELD.—The trustees of the village of Mansfield have decided to buy the light plant recently erected here. The consideration is said to be $7,000.

ROCK ISLAND.—It is reported that the village trustees are contemplating the installation of an electric light plant for lighting the streets of the village.

MASON CITY.—There is talk of constructing an electric light plant, but nothing definite has yet been done. It is stated that an election will soon be held to vote on the question.

ODIN.—The citizens of Odin have indorsed the action of the Town Board in regard to lighting the village by electricity, the power for lighting to be furnished by the Odin Coal Company.

CHARLESTON.—The Charleston Gas & Electric Company has been sold to the Charleston Illuminating Company for a consideration of $240,000. Congressman W. B. McKinley, of Champaign, heads the new company.

KIRKWOOD.—The Kirkwood Electric Company, which has just been incorporated with a capital of $12,000, will operate an electric-light, heat and power plant in Kirkwood. J. F. White, J. F. Taylor and R. M. Houston are the incorporators.

PAWNEE.—Arthur Carswell has purchased the electric light plant from Alvin Underwood.

EAST ST. LOUIS.—The St. Clair Light & Power Company, of East St. Louis, has obtained a franchise from the East St. Louis City Council to erect poles and to string wires and furnish electricity in East St. Louis, provided that within a year the company constructs an electric light plant with appliances to cost not less than $50,000. C. L. Gray is president of the company and R. W. Sikking is secretary. The company was recently incorporated for a nominal sum.

INDIANA.

FLORA.—Dr. Ross, of Wabash, is interested in the construction of an electric light plant at Flora.

PLAINFIELD.—W. W. Wilson, of Danville, has received the contract for constructing an electric light plant at Plainfield.

KEWANNA.—The Kewanna Light Company has been incorporated with a capital of $15,000. Dr. A. Armstrong is president.

ALEXANDRIA.—The Alexandria Electric Light & Power Company has decided to install a new system and add 25 arc lamps to the city lighting system.

CROWN POINT.—The Crown Point Electric Company is making arrangements for the rebuilding of its plant. Many improvements will be embodied in the new plant, which will have a greater capacity than the old one.

MARION.—The Citizens' Heat & Light Company, at a recent directors' meeting, decided to go out of business. An assessment of one per cent. will be levied on all stockholders to meet the obligations of the company.

RICHMOND.—The municipal electric lighting and power plant seems to be growing in favor and increasing its net receipts a little each month. The superintendent's report for April shows that the receipts for lighting and power were $4,417.04, and the operating expenses $1,567.10, leaving a net balance of $2,849.94 to be turned over to the city treasury.

ELKHART.—The fight between the Hen Island dam interests, which furnish the electric light and power for South Bend, Mishawaka and Elkhart, and the Elkhart City Electric Company is ended by the purchase of the latter by Charles A. Gapen, who is believed to represent the Hen Island syndicate. The consideration is said to be $250,000, which is less than the plant cost.

MONTICELLO.—The Tippecanoe Hydraulic Company is the name of a new company incorporated recently to utilize the waterpower in the Tippecanoe River near Monticello. The capital stock is $300,000. A. A. McKain, of Indianapolis, is president. It is proposed to build four dams about six miles apart, the first to be built at once at Norway, one mile north of Monticello. In this plant the company will invest $196,000. The company proposes to furnish electricity for lights and power to Lafayette, Logansport, Delphi, Monticello, Brookston and Frankfort. Mr. McKain has purchased all the land adjacent to the power sites. There is much interest manifested in the project, which is deemed perfectly feasible. C. D. Meeker and D. W. Thompson, Jr., of Frankfort, are also interested.

FRANKFORT.—Capitalists of this city and Kokomo have organized the Indiana Hydraulic Company, with a capital stock of $200,000, and filed articles of incorporation. The company was organized with officers as follows: Eugene Rush, Frankfort, president and general manager; J. C. Dewees, Kokomo, vice-president; N. W. Hanna, Frankfort, secretary and assistant manager; Judge

J. V. Kent, Frankfort, treasurer and general counsel. These men own all of the stock. It is given out that the company will manufacture electricity, and they claim that they have already contracted for their entire output to an electric railway company that contemplates building a road in the State within the year. The company has already determined upon its location, but for the present declines to make this public. They will build a dam of solid cement thirty feet high and 368 feet in length, and claim that the water-power thus obtained will be sufficient for all demands.

INDIAN TERRITORY.

SULPHUR.—The Sulphur Light & Power Company has been incorporated with a capital stock of $100,000.

WYNNEWOOD.—The Council has granted S. E. Hutchins, of Whitehall, Wis., a franchise for an electric light plant.

MUSKOGEE.—H. Von Schon, Wayne County Bank Building, Detroit, has been selected by the Grand River Power Company (C. N. Haskell, president, Muskogee) to report on the water development of Grand River. About 11,000 horse-power is probably feasible within a reasonable transmission distance from Muskogee.

TISHOMINGO.—C. N. Wells, of Tishomingo, and other interested parties have engaged H. Von Schon, Wayne County Bank Building, Detroit, Mich., to examine and report on the water power development of Blue River. If the engineer's report is favorable a company will be organized headed by C. H. Wells, of Tishomingo.

IOWA.

CONRAD.—This city is to have an electric light plant soon.

GLENWOOD.—The Glenwood electric light plant is to be enlarged and improved.

SHELDON.—O. E. Logan has let the contract for the construction of a large power plant.

SIOUX CITY.—The Sioux City Gas & Electric Company will expend about $100,000 in improvements.

ESSEX.—There seems to be considerable agitation here in favor of establishing a municipal electric light plant.

IOWA FALLS.—The Peterson Light, Heat & Water Company of Iowa Falls proposes building a power line to Alden.

CLARINDA.—Plans are being prepared by the Lee Electric Light Company for the erection of a new power house here.

FORT MADISON.—The Fort Madison City Council has voted to install thirty-six additional arc lamps for street lighting.

DUBUQUE.—The City Council is discussing the question of putting in incandescent electric lights in the alleys of the business part of this city.

OTTUMWA.—Contracts have been let by the Ottumwa Traction & Light Company for the building of a new power house in this city and the installing of new machinery at an approximate cost of $150,000.

IOWA FALLS.—The Iowa Falls Electric Light & Power Company's heat and light plants have been transferred to the Pearson Heat, Light & Water Company, a Des Moines corporation. The present officers will be retained. The transfer follows an option given the Des Moines company's agents a short time ago. It is stated that the new company contemplates improvements and will add a heating system.

WATERLOO.—Mr. Austin Burt, the newly elected president of the Iowa Electrical Association, is general manager of the Waterloo & Cedar Falls Gas & Electric Light Company. Mr. Burt was born in Detroit 35 years ago and received a public school education, later going to Cornell University. Before completing his course as mechanical engineer at Cornell, he left to accept a position with the E. P. Allis Company, and for five years was assistant to Mr. Edwin Reynolds. In 1900 he returned to Cornell to complete his course and get his degree as mechanical engineer. His graduating thesis was on a test of the Buffalo street railway, of which he had charge. Upon graduation he was elected a member of Sigma Xi, the scientific honor society, and also won the Sibley prize in mechanical arts, both of which serve to show his high attainments as an engineering student. Upon graduation he took the management of the Cedar Falls Light, Heat & Power Company. In 1902, this company was consolidated with the one at Waterloo, and Mr. Burt became superintendent of the electrical department. Later he was made general manager of the whole property. He has always been a most useful member of the Iowa Electrical Association, and the Association has made a very wise choice in placing him at the head for the coming year. His ability to thoroughly analyze all operating problems and to make intelligent operating statistics in bettering conditions, make him valuable both to the company and to the Association.

KANSAS.

RANTOUL.—The Rantoul Light & Heat Company has been incorporated with a capital of $2,000.

MINNEAPOLIS.—R. E. Jackman is said to have sold his mill and electric light plant to S. E. Jackman.

TOPEKA.—The question of combining the city electric light plant with the Harrison Street pumping plant of the water works is under consideration.

FRONTENAC.—Both the street railway company and the Mount Carmel Coal Co. are applicants for a franchise for lighting the city by electricity.

COTTONWOOD FALLS.—The City Council is reported to have granted W. G. Smith, of Bolivar, Mo., a franchise for an electric light and power plant.

WINFIELD.—The special election to vote on the proposition to issue bonds to the amount of $15,000 for completing the electric light plant was lately carried.

GIRARD.—The city of Girard has engaged W. K. Palmer, consulting engineer, Kansas City, Mo., in connection with improvements about to be made in the electric lighting plant and water works of this city.

HUTCHINSON.—The Committee on Lighting has submitted a report to the City Council, recommending the construction of a municipal electric light plant at a cost of $25,000, and to contract with Emerson Carey to furnish the current to the plant.

LAWRENCE.—An option on the Lawrence electric light plant has been given to a company to be known as the Lawrence Light, Heat & Power Company. The stockholders of the new company are Lawrence men, and it is the intention to take over the property at once and to make repairs, changes and improvements. It is planned to spend about $30,000 at once in an enlargement of the plant so it will be adequate to meet the demands upon it.

KENTUCKY.

NEWPORT.—Bids will be received by the General Council of the city, on June 8, for the exclusive franchise to lay, maintain and operate gas pipes, etc.

CENTRAL CITY.—B. F. Creel writes that a company is about to be organized to construct an electric light plant at a cost of $10,000. R. B. Culbertson is also interested.

CARLISLE.—Press reports state that the City Council will soon offer for sale a 10-year lighting franchise, agreeing to pay $90 per arc light per year for 25 or more lights to burn all night.

PADUCAH.—David G. Wright, of St. Louis, Mo., and other St. Louis and New York capitalists are interested in the construction of an electric light and power plant here, to cost from $300,000 to $500,000.

DANVILLE.—The Danville Light, Power & Traction Company has been organized in this city by electing Hon. Chas. C. Fox, local attorney, as president of the concern. The other officers chosen were: Walter T. Scott, of Georgetown, Ky., vice-president; Arnold Honegger, of St. Louis, Mo., secretary, treasurer and general manager. Work has been commenced on the new power house, which will be pushed to completion as rapidly as possible.

GEORGETOWN.—The Georgetown Water, Gas, Electric Light & Power Company has been reorganized under the style of the Georgetown Water, Light, Heat & Power Company, and has filed articles of incorporation showing its capital stock to be $250,000. A steam-heating plant will be added to the equipment and a new gas plant will be erected. The incorporators are named as David J. Hauss and Ross Holzman, of Cincinnati; R. W. Nelson and F. X. Long, of Newport, and S. L. Allen, of this city.

LOUISIANA.

ROBELINE.—This town is to be supplied with electric lights.

LAKE CHARLES.—The City Council is reported to have decided to call an election to vote on issuing $60,000 bonds to build a municipal electric light plant or purchase plant of the local electric light company.

NEW ORLEANS.—The formal transfer of the plant of the Capital Light & Power Company to the Baton Rouge Electric & Gas Company has taken place. The plants of both companies will be operated until the plant of the Baton Rouge Electric & Gas Company is enlarged.

SHREVEPORT.—J. F. McCulloch, of St. Louis, Mo., estimates the cost of constructing a municipal electric light plant at $171,000. This provides for a plant with a capacity of 10,000 incandescent lights of 16 candle-power each and 200 street arcs of 2,000 candle-power each.

MAINE.

DOVER.—The Eastern Electric Company has filed articles of incorporation, with a capital stock of $10,000. W. C. Woodbury is president, and F. E. Guernsey is treasurer, both of this city.

PORTLAND.—The Centerville Light & Trac- Company is installing a complete underground conduit system. G. M. Gest, of New York and Cincinnati, was awarded the contract for the work.

PORTLAND.—The Centerville Light & Traction Company, of this city, capitalized with $500,000, has been incorporated by M. W. Baldwin, H. E. Mason and others, to operate an electric lighting plant.

BUCKFIELD.—Articles of incorporation have been filed by C. N. Taylor, of Wellesley, Mass., and H. A. Irish and F. R. Dyer, of Buckfield, for the Buckfield Water, Power & Electric Light Company. The company's capital is placed at $25,000.

CARIBOU.—The new owners of the Caribou Water, Light & Power Company, George W. Irving, J. P. Donworth and E. E. Haynes, have taken possession. George W. Irving was chosen president, E. E. Haynes, general manager and treasurer; J. P. Donworth, clerk.

BANGOR.—The Emerson Lumber Company, of Bangor, is planning to install an electric lighting plant at its new mill in Island Falls, the intention being to have an installation large enough to furnish street lights in the adjacent villages and to supply current to stores and residences.

MARYLAND.

BALTIMORE.—The Mount Washington Electric Light & Power Company has begun the erection of a new power-house on the site of the present one. The power-house will be twice the size of the old one and will be built of brick and steel. The roof will be of slate. The building will be equipped with the most improved machinery when completed. John A. Sheridan & Co. have been awarded the contract for the erection of the building.

HAGERSTOWN.—The Street Commissioners of Hagerstown will enlarge the municipal electric light plant and have awarded to the Buckeye Engine Company a contract to put in a 500-h.p. engine at a cost of $7,285, and a contract has been given to the Westinghouse Electric Company to put in a generator for $5,750. This will double the capacity of the electric plant, which is now being operated at a profit. According to a report just submitted the streets of Hagerstown during the past year were lighted at a cost of $44.43 per arc light a year, against $00.59 the previous year. Prior to the establishment of the municipal plant the city paid the Hagerstown

Street Railway Company $75 per arc light a year.

MASSACHUSETTS.

NORTHBORO.—The Blair Light Company has been chartered with a capital of $75,000. Thomas H. Blair is president and treasurer.

EASTHAMPTON.—The directors of the Easthampton Gas Company have voted to construct a new electric light plant for street lighting.

HAVERHILL.—E. P. Shaw has made a proposition to the Amesbury Electric Light, Heat & Power Company to supply electric light at Salisbury Beach.

WELLESLEY.—The citizens have voted to appropriate $32,000 for the construction of an electric lighting substation. The town will purchase current from Vincent Goldthwait, of Westboro.

NANTUCKET.—E. A. Chapel, Receiver's Agent, Nantucket Gas & Electric Co., writes that from $10,000 to $25,000 will be expended in improvements. No engineer has been appointed as yet.

NORTHAMPTON.—The Northampton Electric Lighting Company has placed an order with the Buckeye Engine Company, of Salem, Ohio, for a tandem compound engine of 625 horse-power, to take the place of a 100-h.p. Corliss engine.

LYNN.—The Lynn Gas & Electric Company has applied for permission to increase the capital stock by 2,300 shares at par value $100 a share. The company contemplates the immediate expenditure of about $526,700 for gas, electrical and other equipment.

FALL RIVER.—The stockholders of the Fall River Electric Light Company have voted to increase the capital stock from $350,000 to $600,000, the increase to be used for the construction of a new generating plant on the company's wharf property and also to extend its system of distribution.

CHELSEA.—The Chelsea Board of Aldermen has passed the order authorizing the installation of a new street lighting system. The order authorizes the mayor to obtain bids. The number of arc electric lights in the city will be cut down to 74, and the incandescent system will be employed.

MICHIGAN.

ALBION.—The Council has granted a 30-year franchise to the Albion Electric Light Company.

GRAND RAPIDS.—A franchise has been granted to the Grand Rapids & Muskegon Water Power & Electric Company.

BATTLE CREEK.—The citizens are reported to have voted in favor of municipal ownership of the gas and electric light plants.

HOWARD CITY.—A 10-year franchise has been granted A. O'Donnell, of this city, by the Council to furnish electricity for all uses.

TRAVERSE CITY.—A committee has been appointed to visit plants in certain Michigan cities and prepare prices on a plant of from 100 to 200 light capacity.

SAULT STE. MARIE.—W. F. Kingman, who has for some time been general manager of the Edison Sault Electric Company, has accepted a position as manager of the power department of the Detroit Edison Company.

MENOMINEE.—Wm. Holmes, of Menominee, writes that it is proposed to develop the water power of Menominee River, at a probable cost of $250,000, but nothing definite has yet been done. Engineer, N. M. Edwards, of Appleton.

SAULT STE. MARIE.—The Edison Sault Electric Company is reported to have filed a mortgage for $500,000, the proceeds to be used in extending the power plant. The first section of the new plant will develop between 2,500 and 3,000 horse-power.

DETROIT.—The Miami Avenue station of the Detroit Edison Company was the scene of an accident in the bursting of one of the large generators which was running at the rate of 635 r.p.m. Pieces of the commutator were thrown in every direction, doing considerable damage. The manager's desk which stood near by was entirely demolished.

ROSE CITY.—The Rose City Manufacturing Company is figuring on putting in a city electric lighting plant. Andrew King, an electrician of Bay City, has been figuring out the cost. Superintendent W. A. Humphrey will confer with Greif Bros., of Cleveland, who own the plant of the company and thinks it probable that the city will soon be lighted by electricity.

MINNESOTA.

GIBBON.—This town is considering the construction of an electric light plant.

ATKIN.—It is stated that the Aitkin Power & Light Company will construct a water power plant at a cost of $20,000.

MARSHALL.—It is reported that improvements have been recommended to the water works and electric light plant.

MELROSE.—Oscar Claussen, of St. Paul, will prepare plans for the proposed water works and electric light plant. The probable cost of work will be $30,000.

MOORHEAD.—Bids have been advertised for furnishing a 300-k.w. generating unit for the electric light plant, at a probable cost of $20,000. E. P. Burch, Minneapolis, is the engineer.

SOUTH ST. PAUL.—The South St. Paul Power, Heating & Lighting Company is about to petition the Village Council for a franchise. Emil Erick and John Coates are among the incorporators.

MINNEAPOLIS.—The Hughes Electric Company, of this city, recently filed articles of incorporation with a capital stock of $100,000. A central lighting plant will be established, supplying both gas and electricity, at a cost of about $50,000.

MISSISSIPPI.

STARKVILLE.—It has been voted to issue $8,000 bonds to improve the water works and electric plant. T. M. Cummings is city clerk.

LAUREL.—The Laurel Improvement Company has been granted a franchise by the city of Laurel for a light and power station. It will begin at once the erection of a $25,000 plant.

MONTROSE.—The Montrose Lumber Company will ask for a charter with a capital of $25,000 to construct an electric light plant and water works among other enterprises. Incorporators: John O. Gusham, W. P. Hutto and others.

GREENVILLE.—The Greenville Light & Power Company is reported to have purchased the stock and plant of the Delta Electric Light, Power & Manufacturing Company, but none of the particulars of the transaction have been made public at the present writing.

MERIDIAN.—The Mayor and Boards of Aldermen and Councilmen have granted L. W. Ullman a franchise for the operation of an electric light and power plant for a period of 45 years, also the contract for lighting the city for 5 years at $69.50 each for 200 arc lights.

HATTIESBURG.—The organization of the Hattiesburg Traction, Light & Power Company, capitalized at $250,000, has just been perfected with the following named officers: President, H. A. Camp, Lumberton; first vice-president and general manager, H. L. McKee, Meridian; second vice-president and chairman of executive committee, George L. Hawkins; secretary and treasurer, A. F. Thomasson.

MISSOURI.

JOPLIN.—The board of public works is preparing to spend $30,000 on the city's electric light plant.

BRECKENRIDGE.—At a special election a proposition to bond this city for $10,000, for the purpose of putting in an electric light plant, was carried.

MONTANA.

HELENA.—The Rocky Mountain Development Company, capitalized at $50,000, recently filed its articles of incorporation. Among those projecting the new enterprise are F. L. Sizer and A. W. Martin.

GLASGOW.—A. W. Mahon, city engineer, writes that estimates have been submitted to the mayor and Council for water works and an electric light plant; a sewerage system will probably be constructed, too, the entire cost to be $60,000.

NEBRASKA.

WISNER.—The special election held recently to decide the matter of issuing bonds to the amount of $9,000 for the constructing of a lighting system for the village, resulted in a victory for the bonds.

GRAND ISLAND.—The citizens have voted to construct an electric light plant, to cost not more than $35,000. It is proposed to vote on bonds later, which action will determine the matter. C. A. Baldwin is city engineer.

OMAHA.—The city has entered into a four-year agreement with the Omaha Electric Light & Power Company, whereby the latter is to light the city's streets for $75 per light per year. This is a reduction of $19.50 from the present rate. The city is to use at least 600 lights at all times.

ALMA.—Bids will be received by the City Clerk until June 8 for furnishing material and constructing an electric light plant and water works system, consisting of approximately a 10-in. tubular well, power house, machinery setting, etc.; two 60-in. x 14-ft. return flue tubular boilers and one 150-h.p. heater, one 60-h.p. high speed engine, a 40-k.w. direct-current dynamo, fixtures, poles, wire, lamps, etc., a simple, duplex steam fire pump, a boiler feed pump and a deep well power pump, about 1½ miles of water pipe with hydrants, valves, etc., a standpipe or elevated steel tank and tower; also gas producer plant. M. A. Earl, Contracting Engineer, 1416 First National Bank Building, Chicago, Ill.

HASTINGS.—The city of Hastings has arranged with Allis-Chalmers Company, of Milwaukee, for an equipment of an electric lighting plant. The generating unit will consist of a heavy-duty cross-compound Reynolds Corliss engine, with cylinders 14 and 22 in. in diameter and a 36-in. stroke, direct-connected to a single-phase Bullock alternator. The engine will be constructed at the West Allis Milwaukee Works and the electrical apparatus furnished by its electrical department, the Bullock Electric Manufacturing Company, of Cincinnati. The generator is to be provided with an exciter, rheostats and other auxiliary apparatus, and a switchboard panel will be installed.

NEVADA.

RENO.—The power plant of the Reno Power, Light & Water Company has been almost wrecked again. The transformers were burned out and damage to the extent of about $7,000 is reported.

NEW HAMPSHIRE.

LACONIA.—Mr. F. H. Corson has become superintendent of the Winnipesaukee Gas & Electric Company, of this city. He had held this position before.

CONCORD.—At a meeting of the stockholders of the Concord Electric Company in this city, it was voted to increase the preferred stock of the company by a new issue of $50,000. The proceeds will be used for perfecting the company's plant at Sewall's Falls.

NEW JERSEY.

PLEASANTVILLE.—The Shore Electric Light Company has sold its plant to the new Atlantic City Company, which obtained a franchise from the Borough Council.

HIGHTSTOWN.—Mayor Norton is agitating the matter of municipal ownership, but his resolution submitted to the Council did not seem to be considered very favorably.

BEVERLY.—The Cinnaminson Electric Light, Power & Heating Company, of Riverside, has secured the contract for lighting the city by electricity for five years, at $2,850 per year.

TRENTON.—The National Light & Improvement Company has been incorporated here with a capital of $2,000,000, to supply cities with gas and electric light. Incorporators: H. C. Scott, of St. Louis, Mo.; L. B. Dailey and Thomas F. Barrett, both of Jersey City.

PATERSON.—The Paterson Electric Light, Heat & Power Company has been incorporated with a capital stock of $500,000. The incorpora-

tors are Peter S. Van Kirk, Angelo H. Knapp, Thomas J. Arnold, Mangold H. Ellenbogen, Robert Gaede, Walter Bamford and Joseph Bamford.

BRANCHVILLE.—The certificate of incorporation of the Branchville Electric, Water, Power & Lighting Company has been filed in the clerk's office, at Newton. The incorporators are Charles H. Crisman, of Branchville; Samuel S. Wills, of Andover, and E. T. Wills, of Stanhope. The company is capitalized at $30,000, and has $1,000 paid in.

NEW YORK.

ILION.—The Governor has signed the bill legalizing issue of bonds for the repair of the electric light plant.

WATKINS.—The property of the Watkins Gas & Electric Light Company has been sold to M. L. Dreisbach, of Easton, Pa., for $7,500.

AUBURN.—The City Council has let the contract for lighting the city with electricity to the Auburn Light, Heat & Power Company.

WATERFORD.—The Waterford Electric Light, Heat & Power Company has filed a certificate of increase of capital from $50,000 to $500,000.

BLASDELL.—The Blasdell Electric Company has been incorporated; capital, $50,000. J. B. Wall, of Buffalo, is one of the incorporators.

WATERFORD.—The Waterford Electric Light, Heat & Power Company of Waterford, has increased its capital stock from $50,000 to $500,000.

NYACK.—A franchise has been granted the Rockland & Orange County Electric Company, of Monroe, to establish a line in the town of Chester.

HERMON.—Cullimore & Killelea, of Hermon, are interested in the construction of an electric light plant. Geo. Gould, of Ogdensburg, is the engineer.

PHOENIX.—The Phoenix Fuel, Light & Water Company has been incorporated with a capital of $100,000 by J. O. Hawley and L. C. Hall, of Canandaigua.

CHATHAM.—The Lindenwald Light, Heat & Power Company, of Chatham, has been incorporated; capital, $25,000, to operate in Columbia County and the City of Hudson.

CAZENOVIA.—The Cazenovia Electric Company has been incorporated; capital, $30,000. Incorporators: R. F. Hubbard, of Cazenovia; R. S. Brewster, of New York, and others.

HEMPSTEAD, L. I.—The Nassau & Suffolk Lighting Company has been formed at Hempstead; capital, $50,000. Directors: S. M. Havens, D. T. Ackerly and F. C. Henser, New York.

NEW YORK CITY.—The Marshall Light, Heat & Power Company has been formed; capital, $150,000. Directors: H. G. Villard, Gustav Ulbricht, Roger Lewis, all of New York City.

UTICA.—The Central New York Power Company, of Utica, has been incorporated; capital, $1,000,000. Directors: Wm. E. Lewis, Utica; Harry Patton, Whitesboro and others.

NORTH TONAWANDA.—It is stated that bids will be received until June 6 by Geo. J. Smith, City Clerk, for lighting the city for a period of one or three years from August 1, 1905.

FULTON.—The Overland Power Company has been incorporated; capital, $20,000. Directors: Simon B. Storer and Geo. W. Pulver, of Syracuse, and Louis W. Emerich, of Fulton.

NEW YORK CITY.—Plans have been filed for a three-story power station to be constructed by the New York Edison Company on First Avenue and 39th Street. It will cost about $1,500,000.

YONKERS.—The Lawrence Park Heat, Light & Power Company has been incorporated with a capital stock of $50,000. The directors are W. V. D. Lawrence, J. J. Lannin and A. W. Lawrence, New York.

CANTON.—The electric light company plans to make improvements in its plant to the extent of $10,000. New buildings will be erected, and two 100-h.p. engines and one 120-kilowatt generator will be installed.

TROY.—The Troy Public Service Company has been incorporated, to operate in Rensselaer and Albany Counties; capital, $100,000. Directors: Michael F. O'Connor, Chas. S. Aldrich and Edw. Murphy, 2d, of Troy.

HOLLEY.—The Village Trustees are stated to have granted the Niagara Falls Electric Transmission Company a franchise to erect poles and construct lines in the village for electric light, heat and power purposes.

TROY.—The Troy Public Service Company has been formed at Troy to supply gas and electricity for light, heat and power purposes; capital, $100,000. Directors: Michael F. O'Connor, Charles S. Aldrich and Edward Murphy, 2d, Troy.

BELLPORT.—The Bellport Lighting Company has been incorporated with a capital of $10,000. Directors: Edmund F. Hawkins, Isaac H. Cleaves, George Carman, Alfred S. Osborne, Everett M. Price, William F. Gardner and Henry E. Corwin, of Bellport.

OSSINING.—The Northern Westchester Lighting Company, of Ossining, has been incorporated with a capital of $1,000,000, to supply gas and electricity for light, heat and power purposes. Directors: Wm. J. Bagnell and Jas. H. Hagerty, of Brooklyn; Alex. Keogh, of New Rochelle, and others.

SARATOGA SPRINGS.—P. F. Roohan, formerly superintendent of the Saratoga Springs Electric Light & Power Company, has been appointed manager of the lighting and power division of the Hudson River Power Company, with special charge of the plants between Albany and Glens Falls.

SANDY HILL.—The Glens Falls Light Company, of Glens Falls, has secured a 50-year franchise to operate in Sandy Hill. The company will furnish incandescent lights for 10 cents per k.w.-hour and supply current for manufacturing purposes at 5 cents per k.w.-hour; 2,000-c.p. arc lights to be $70 per lamp per year.

BROOKLYN. — The Interinsular Heating, Lighting & Power Company has been incorporated to manufacture and sell gas and electricity for light, heat and power purposes in Queens, Suffolk, Nassau and Richmond; capital stock, $50,000. Directors: John Eckhardt, of New York City; Elbert D. McLean, of Yonkers, and Edward A. Cracke, of Brooklyn.

ALBANY.—The Electric Power & Transmission Company of Niagara County has filed articles of incorporation with the Secretary of State. It has $5,000,000 capital, and may operate anywhere between Albany and Buffalo. Its directors are Edward B. Bruce, Allan C. Rearick, Edward E. Stowell, Frank H. Cole, New York, and John J. Daly, Brooklyn.

SYRACUSE.—The Oswego River Power Transmission Company, of Syracuse, has been incorporated, to supply gas and electricity for power, light and heat in the counties of Onondaga and Oswego in particular, with the privilege of operating all through the State; capital, $20,000. Directors: Simon B. Storer, Louis W. Emerich and Geo. W. Pulver, of Syracuse.

MALONE.—The Malone Light & Power Company has under consideration a proposition for installing a complete duplicate plant at its works one mile north of here. The present plant is on the west side of the river, and the new one will be on the east side, directly opposite. Plans are now being made for the new equipment, and bids have been asked for machinery and supplies.

ALBANY.—The Hanover Light & Power Company, of Albany, has been incorporated with a capital of $2,000,000 to furnish gas and electricity for light, heat and power in Albany, Buffalo, Utica, Syracuse, Rochester, Troy and other cities in New York State. The incorporators are Edmund G. DuMazuel, Fred K. Morris, of New York, and Wm. Brower and Maurice S. Decker, of East Orange, N. J., and others.

BUFFALO.—The Western Counties Transmission Company, of Buffalo, has been incorporated; capital, $2,000,000. Directors: Robt. W. Pomeroy, Jos. G. Dudley, Harry T. Ramsdell and others. This company is to cover the counties of Erie, Niagara, Chautauqua, Cattaraugus, Genesee, Orleans, Wyoming, Allegheny, Monroe, Livingston, Ontario, Wayne, Yates, Schuyler, Chemung, Cayuga, Tompkins, Tioga, Oswego, Seneca, Onondaga, Cortland, Broome, Oneida, Madison, Chenango and Herkimer.

NORTH CAROLINA.

WAYNESVILLE.—The citizens have voted to install a system of electric lighting.

WASHINGTON.—The citizens here voted $15,000 additional bonds for an electric light plant for the city.

FAYETTEVILLE.—The Fayetteville Gas & Electric Company has been sold to J. H. Martin, of New York.

KINGS MOUNTAIN.—The citizens have voted to issue $15,000 bonds for the construction of an electric light plant.

WILMINGTON.—Bids will be received until June 8 by A. M. Waddell, Mayor, for lighting the city with gas and electricity.

MT. GILEAD.—The Mt. Gilead Telephone & Electric Light Company has been chartered by J. R. Blair and others; capital, $25,000.

WINSTON.—An election has just been carried for bonds at Winston in the interest of the interurban electric railway for which $37,000 was voted.

MOREHEAD CITY.—It is reported that the question of installing an electric light plant in connection with a water supply for fire protection is under consideration.

OXFORD.—A charter has been issued to the Oxford Water & Electric Company with $50,000 capital, for the purpose of constructing waterworks and an electric light plant for this town. The incorporators are Harry L. Millner, of Morgantown; W. T. Sherman, of Washington, D. C.

FAYETTEVILLE.—The Cape Fear Electric Power Company has offered to buy the city electric light plant and all other appliances, subject to a mortgage of $15,000 in bonds running from 1902 to 1932. To meet them, the company guarantees to pay $750 interest annually, and to set aside such a sinking fund as will meet the bonds at maturity. The company engages to furnish 51 arc lights of 1200 candle power, the city having the option of increasing this number when desired.

CHARLOTTE.—It is reported that all of the numerous water powers on the Catawba River, where thousands of horse-power are available and several already developed, are to be consolidated. Dr. Gil Wylie, of New York, and president of the Catawba Power Company, of Fort Mill and Charlotte, is at the head of the interests concerned in the rumored developments. The Catawba people have recently secured control of a valuable power near Camden, S. C., for something like $125,000.

GREENSBORO.—Mr. R. H. Gamwell is general manager of the Greensboro Electric Company, and we learn that the Greensboro Railway & Light Company has been chartered by the Secretary of State with $750,000 authorized capital for the purpose of purchasing, constructing and operating street railways and light plants, the subscribers to the stock being F. R. Williamson, of Flemington, N. J.; R. H. Gamwell, of Greensboro; W. M. Wherry, Jr., and W. A. Morgan, of New York, and W. W. Gamwell, of Pittsfield, Mass.

NORTH DAKOTA.

ENDERLIN.—C. C. Dalrymple is stated to have secured a franchise for an electric plant.

WILLISTON.—The citizens have voted to construct an electric light plant and install a system of water works.

RUGBY.—A. H. Jones is said to have secured a franchise for an electric light plant and a telephone system.

OHIO.

SIDNEY.—A franchise has been granted to the New Bremen Electric Light Company to light the streets of this city.

HENO.—The Middletown Electric Light & Power Company has received the contract to light the streets of this city.

McCOMB.—The electric light plant has been purchased by this town for $5,000. Bonds will be issued to pay for the same.

WARREN.—Plans are being made to greatly enlarge the plant of the Youngstown Gas & Electric Company on North Avenue.

BELLEFONTAINE.—Bellefontaine has voted

in favor of issuing $50,000 bonds for improving the municipal electric light plant.

CLEVELAND.—The People's Electric Light & Power Company is reported incorporated with a capital of $10,000 by H. I. Emerson, W. McBride, D. F. Crane and others.

LOVELAND.—The Loveland Citizens' Electric Company has been incorporated with $100,000 capital stock by H. C. Hubbell, C. B. Vandervort, Joseph Baeth, H. S. Tunneson and H. C. Ramsey.

NORWALK.—The Board of Public Service is reported to have granted to the Cleveland & Southwestern Traction Company (E. F. Schneider, purchasing agent, Cleveland) a franchise to light Norwalk.

COLUMBUS.—The Columbus Public Service Company will increase its capital an additional $250,000 to be used in enlarging the plant at 17th and Mound Streets and in extending the hot-water system into sections on the East Side.

BARNESVILLE.—The contract for lighting the village by electricity has been awarded to the Barnesville Gas & Electric Company, of Barnesville, at $75 per light per year for arc lights, and $19 per light per year for incandescents.

SPRINGFIELD.—The Springfield Light & Power Company, which was owned by the American Railways Company, of Philadelphia, has been bought by the People's Light, Heat & Power Company, of this city. The new concern is a combination of all the public service companies and is said to be incorporated for $2,000,000. Among the incorporators are: F. M. Hagan, Walter L. Weaver and John F. Zimmerman.

HAMILTON.—The Hamilton Gas & Electric Company will expend about $500,00 in improving the plants recently acquired through a merger of the Hamilton-Otto Coke Company, the Hamilton Electric Light Company, and the Hamilton Gas & Coke Company. The improvements will include a new electric plant, new overhead construction for electric service and general enlargement of the three plants.

ELYRIA.—The stockholders of the Ford Light & Heating Company have organized by electing the following named officers: J. C. Hill, president; E. A. Berry, vice-president; L. B. Fauver, secretary; J. C. Smith, treasurer; E. E. Martin, assistant treasurer. The company will move its plant to Elyria from Garretsville, where it was formerly known as the Ford Lighting Company. The capital stock has been increased from $25,000 to $50,000.

CINCINNATI.—The Cincinnati Gas & Electric Company, at its annual meeting, arranged for large expenditures on new gas and electric light development. The report of President Keenan showed a gain for the year of 1,169 consumers of electricity. During the year nineteen isolated electric light plants were shut down in order to change over to the company's service. Two-thirds of the entire voting stock was represented and resulted in the election of the following board of directors: Stephen R. Burton, J. T. Carew, Briggs Cunningham, R. A. Holden, J. B. Foraker, Jr., A. H. Hinkle, Norman Kenan, M. E. Moch, W. Cooper Procter, C. H. Rowe, J. G. Schmidlapp, W. S. Rowe, M. M. White and Casimir L. Werk.

OKLAHOMA TERRITORY.

GUTHRIE.—The Guthrie Electric Light & Power Company, of which Thomas H. Smith is president, will enlarge its plant in the near future.

McLOUD.—The business men of this city are considering the proposition of several promoters to put in an electric light plant. S. J. Williams is said to be among those interested in the project.

OREGON.

HARRISBURG.—The City Council is reported to have decided to issue bonds for water works and an electric light plant.

IONE.—It has been decided to issue bonds to cover the cost of a municipal electric lighting plant, which will be installed immediately.

CASTLE ROCK.—A franchise has been granted to the Kalama Light & Power Company allowing it to furnish electric light and power.

PRAIRIE GROVE.—C. L. Cummings & Son are ready to receive bids for the construction of an electric light plant to cost from $2000 to $3000.

BAKER CITY.—The Baker Light & Power Company has been incorporated with a capital stock of $400,000, by C. A. Johns, F. N. Averill and J. H. Parker. This corporation takes over the Rock Creek Power Company and the Baker City Gas & Electric Company.

WASCO.—W. M. Barnett, of Wasco, president and manager of the Wasco Milling Company, writes that it is proposed to construct an electric light and power plant to cost from $35,000 to $40,000. Engineer A. M. Mohr, The Dalles. The plant will be located about thirteen miles east of Wasco on John Day River.

LA GRANDE.—The Grande Ronde Electric Company and the La Grande Storage Water Company have consolidated. The directors of the company are J. A. Thronsen, Walter M. Pierce, W. G. Hunter and T. H. Crawford. Power on the Cove line will be developed first. The Grande Ronde Company gets power from Cove and the La Grande Company from Morgan Lake.

SALEM.—The management of the Citizens' Light & Traction Company, of this city, is making preparations for the proposed electric road from Salem to Portland, Ore. Manager A. Welch announces that plans are being perfected for the establishment of a power-generating plant on the upper Santiam, with a minimum capacity of 15,000 horse-power. The cost of installation for the transmission of power to Salem will be not less than $300,000.

PENNSYLVANIA.

ALLENTOWN.—The Merchants' Light & Power Company has petitioned the Council for a light and power franchise.

YORK HAVEN.—The York Haven Water & Power Company has decided to extend its lines to Lancaster County and in Dauphin County.

SCRANTON.—An ordinance has been introduced in the Council granting a franchise to the West Scranton Light Heat & Power Company.

KENNETT SQUARE.—Bids have been advertised by the Borough Council for lighting the streets, hall and fire engine house in this borough.

READING.—Judge Hassler at Lancaster has awarded control of the Lancaster Electric Light Heat & Power Company to a Philadelphia syndicate, headed by Clarence H. Burr, to reorganize the concern.

MAYTOWN.—This village has contracted to have its streets illuminated by electric lights.

COLUMBIA.—The Council is reported to have passed an ordinance granting a franchise to the Columbia Light & Power Company.

TOWER CITY.—H. T. Bressler has completed arrangements for the erection of a new electric plan to provide lights for this city, Williamstown, Lykens, Wiconisco, Rinerton and Johnstown. The plant will be located here.

SHENANDOAH.—The directors of the Citizens' Electric Light Company have elected officers as follows: president, William Krick; vice-president, W. H. Waters; secretary, J. W. Daddow; superintendent and treasurer, T. F. Bradigan.

FORT WASHINGTON.—Harvey S. Souder and Samuel S. Alderfer, both of Souderton, and others are about to petition the Governor for a charter for the Wissahickon Electric Company, to supply light, heat and power in Whitemarsh Township.

FRACKVILLE.—The Frackville & Gilberton Light, Heat & Power Company has elected as directors W. C. Wagner, John Dunlap, Samuel Bailey, Orval Miller, Garrett Keating, Thomas Lafferty, David Taggart, C. A. Blieler and G. W. Johnson. The officers are: President, David Taggart; secretary, C. A. Blieler; treasurer, L. C. Anstock.

PHILLIPSBURG.—The Phillipsburg Electric Light Company will spend $40,000 in making improvements. New engine and new machinery have been ordered. These will be placed in the power house of the Centre & Clearfield Street Railway Company, whose large boilers will be utilized to furnish the power. The company proposes also to furnish the power for lighting Osceola.

MONONGAHELA.—The option given the Pennsylvania Railroad Company on the property of the Monongahela Electric Light Company and the property formerly occupied by the Monongahela Milling Company at Monongahela has been taken up and it is probable the transaction will be closed at once. Examination of the titles to the properties is being made now, after which the railroad company will take formal possession.

PITTSBURG.—The contract for the electrical construction work and apparatus for the filtration plant being contruction at Aspinwall has been awarded to the Morganstern-Ochiltree Company, of Pittsburg. It includes the installation of a complete power and lighting system, telephone exchange, police and time-clock systems. All the power, lighting and telephone cables will be placed underground, the conduits to include cables sufficient for supplying about 20,000 lights.

WILKESBARRE.—The directors of the Wyoming Valley Gas & Electric Company at a meeting here May 11 approved of work already under way, also recommending an additional expenditure for equipment of power houses and for other machinery. They authorized an expenditure of $75,000 for new gas making machinery and laying new pipe. Ambrose West, of Plymouth; C. H. Gist, of Philadelphia, and W. H. Anderson, of Grand Rapids, Mich., are reported to be among the directors.

YORK.—Charles H. Baer, president of the Merchants' Electric Light, Heat & Power Company, closed a contract with Ephraim Hugentugler, assistant custodian of the York Post Office building, for supplying that structure with current for lighting and power for a period of a year. One year ago the Edison Light Company entered upon the contract to supply the Federal building with current, that corporation being the lowest bidder at that time, but the bid recently submitted by the Merchants' Company against the Edison Company's bid was lower still and the contract was awarded accordingly.

SELINGSGROVE.—Bids will be received June 1 by George W. Agenseller, secretary Middlecreek Electric Company, Middleburg, for constructing a complete water power electric plant, on Middlecreek, two miles south of Selingsgrove, for supplying light, heat and power to Selingsgrove, Sunbury, Northumberland, and perhaps to Middleburg, to consists of a dam across a ravine, about 360 ft.; spillway of dam to be 150 ft. long, dam to be 17 ft. high above water as per print; a tunnel and excavation 1255 ft. long through mountain for head race; two units consisting of four wheels, direct connected to two generators, switchboards, power house and 25 or 30 miles of line construction.

YORK.—The Hillside Water & Power Company and the Susquehanna Water & Power Company have been merged into McCall's Ferry Water & Power Company. The merger is taken to mean that an electric power plant will be installed at McCall's Ferry in the near future. These two companies, while chartered at nominal figures, have invested thousands of dollars in land adjoining the river shores. They have secured every tract of land for miles up and down the river and have hundreds and thousands of dollars tied up until a plant is built and power is being furnished to the large cities. It is stated that New York capitalists are interested. The location of the plant will make it possible to supply current to Baltimore, Wilmington, York, Havre de Grace and Philadelphia.

RHODE ISLAND.

CENTRAL FALLS.—This city, which is supplied with light by the Pawtucket Electric Company, is determined to own its own lighting plant. The present contract with the Pawtucket concern will not expire for five years, but the City Council has already secured an option on a site, and at its next meeting will probably make an appropriation for a suitable structure.

SOUTH CAROLINA.

ORANGEBURG.—The commissioners of public works of Orangeburg have been instructed to se-

cure information as to the best machinery, etc., for improving the lighting system. About $5,000 is to be expended.

COLUMBIA.—The Columbia Electric Street Railway Light & Power Company is to acquire by purchase the Columbia Water Power Company. Mr. F. S. Anable, of Boston, and Mr. Francis K. Carey, of Baltimore, are interested. An auxiliary steam plant costing $300,000 is to be erected to be used in emergencies and the company is to supply motive power to the factories, mills, railway and other plants here.

SOUTH DAKOTA.

VERMILLION.—The citizens have voted in favor of municipal ownership of the electric light plant.

BERESFORD.—A. O. Hanson has purchased the mill and electric light business of M. M. Doyle & Son.

DEADWOOD.—The Lead and Deadwood Electric Light Companies are reported to have been consolidated and will expend about $1,000,000 in the installation of new machinery and building transmission lines; a power plant will also be constructed at Pluma. N. E. Franklin, of Deadwood, is reported interested.

TENNESSEE.

OLIVER SPRINGS.—It is said that Rich Brothers will install an electric-light plant here.

BOLIVAR.—It is proposed to petition the State Legislature for permission to issue $20,000 bonds for water works and an electric light plant.

HARRIMAN.—H. A. Coles, of Atlanta, Ga., has prepared estimates for a new electric light plant for Harriman. He estimates the cost at $40,000.

DRESDEN.—The State Senate is reported to have passed a bill authorizing this city to issue $10,000 bonds for water works and an electric light plant.

CLARKSVILLE.—The Clarksville Street Railway Company has purchased the plant of the Queen City Electric Light & Power Company; extensive improvements will be made.

NASHVILLE.—A bill has been introduced in the Tennessee Legislature providing for a tax of $1,000 on electric light plants of 1,000 lights or over, and $2,500 in cities of 100,000 inhabitants or more.

MEMPHIS.—A committee has been appointed by Mayor Williams to secure information as to cost, etc., of an electric light plant, to be owned and operated by the city at a probable cost of $1,000,000.

KNOXVILLE.—James B. Cahoon, Consulting Engineer, 42 Broadway, New York, N. Y., writes that only preliminary work has yet been done on the proposed plant of the Knoxville Power Company; probable cost of work complete, $2,790,000.

SHELBYVILLE.—Bids will be received by the Light Commission at Shelbyville, Tenn., until June 6 for furnishing twenty or more 2,000-c.p. enclosed arc lamps for street lighting purposes, the prices to be based on a ten-year contract with a franchise for commercial lighting at prices to be proposed by the bidder.

TEXAS.

BRYAN.—The building and operating of an electric light plant here is considered favorably by the committee of aldermen, who were appointed to look into the matter.

MARBLE FALLS.—M. H. Reed is interested in the construction of an electric light and power plant to be constructed here at a cost of $160,000. No engineer has been chosen yet.

GAINESVILLE.—The Gainesville Electric Railway & Light Company, recently incorporated with a capital of $50,000, is preparing to begin active work on its proposed power plant. The company has also been granted a franchise to build and operate a system of electric railways in Gainesville.

CLARKSVILLE.—The Clarksville Light & Power Company has been sold to the Clarksville Light Company, a new concern, composed of D. W. Cheatham, president; B. A. Dinwiddie, vice-president; John W. O'Neill, secretary, and A. M. Graves. The company has also purchased machinery for an ice plant, which it will run in connection with the light plant.

UTAH.

EPHRAIM.—The citizens have voted to construct an electric light plant at a cost of $20,000. Jas. Frost is City Recorder.

COALVILLE.—An election will probably soon be held to vote on issuing $10,000 bonds for the construction of an electric light plant.

OGDEN.—A company will shortly be organized here to establish an electric lighting plant, $30,000 having already been subscribed for the purpose.

SALT LAKE CITY.—The Cramer Electric Company of this city, with a capital of $50,000, has been incorporated. Lee Cramer is president.

SALT LAKE CITY.—Wm. A. Clark, of Salt Lake City, has made application to the State Engineer to appropriate 300-second feet of water from Blacksmiths Fork River for the development of power. It is expected that 2,000 horse-power will be generated, most of which will have to be transmitted for a distance of about sixty miles; total cost of plant and lines will be about $75,000.

VERMONT.

BENNINGTON.—The Bennington Electric Company has taken over the Bennington Water & Light Company.

MONTPELIER.—Mr. J. E. Davidson, who has been connected with the Port Huron (Mich.) Power & Light Company for the past six years as secretary, has resigned that position to accept a similar one with the Consolidated Light & Power Company, of Montpelier, Vt. The latter company has been transferred to Wilbur F. Davison, A. D. Bennett, George Moore, of Port Huron, Mich., and some Eastern associates. The sale was made on a cash basis for about $200,000. The company's system extends from Bolton Falls, 12 miles below this city, to the granite quarries in Barre. It supplies municipal lights for Montpelier and Barre, besides a large number of private lights, and furnishes power for the electric railway and several granite plants. The property has been in the hands of the National Life Insurance Company for some years.

VIRGINIA.

ASHLAND.—It is reported that the Virginia Passenger & Power Company has received the contract for lighting this town with electricity.

RICHMOND.—E. W. Trafford, recently appointed by the city to report on the matter of a municipal electric light plant, is stated to have completed his report and estimates the cost of a plant at $400,000. Mr. Dabney, Chairman Lighting Committee.

WASHINGTON.

UNIONTOWN.—M. J. Shields, of Moscow, Idaho, has petitioned for a franchise for an electric light plant.

SEATTLE.—The Seattle Electric Company is considering the extension of its system to the northeastern part of city.

SEATTLE.—The Mutual Light & Heat Company, of this city, has gone into new hands. N. H. Latimer is now the president.

BELLINGHAM.—The City Council will establish an electric light plant in connection with the pumping plant on Sehome Hill.

PALOUSE.—Reports state that the Palouse Light & Power Company will install a new 260-h.p. compound condensing engine in its power plant about July 1.

SUMAS.—Franchises have been granted to the Sumas Electric Light, Water & Power Company. Work upon the plant is to commence at an early date and it will cost $20,000.

KENNEWICK.—C. E. Wood, of Genesee, Idaho, offers to put in an electric light system and a flour mill here at once if he can secure a franchise for the electric light system.

GOLDENDALE.—H. W. Fellows, of Spokane, is interested in the construction of an electric light plant at Goldendale, to cost about $50,000. Power is to be developed from the falls of the Little Klickitat.

PROSSER.—President E. F. Benson, of the Prosser Falls Land & Power Company, has filed a notice at the office of the county auditor of the appropriation of 5,000 cubic feet of water per second from the Columbia River, to be diverted at Priest Rapids, for the purpose of generating electric power at that point and transmitting the same to Prosser.

WEST VIRGINIA.

MARLINTON.—The Marlinton Light & Water Company proposes constructing water works and an electric light plant here.

WELCH.—The Citizens' Light & Water Company, of Welch, has been incorporated by the Secretary of State. Capital stock, $25,000. Incorporators: W. Burbridge Payne, James A. Strather, Edgar P. Rucker, I. J. Rhodes, M. W. Hutson, Louis Morse, C. D. Brewster, A. Q. Letz, L. Masil, Welch, W. Va.

WISCONSIN.

SPRING VALLEY.—The Council is reported to have granted R. D. Harrison a franchise for an electric light plant.

GREEN BAY.—The Green Bay Gas & Electric Company has been formed, capital $750,000. Incorporators: William Mainland, Ralph M. Burtis and Sinclair Mainland.

BURLINGTON.—In regard to the construction of an electric light plant, for which the citizens recently voted to issue $8,000 bonds, the Council is taking steps to construct a plant with a capacity of fifty 2,000 candle-power arc lamps.

WAUWATOSA.—The County Board of Supervisors, at a meeting at Milwaukee, May 9, is stated to have passed a resolution providing for the appropriation of $100 to be used to prepare plans for the installation of a general light and heating plant and a pumping station for the county institutions at Wauwatosa.

LA CROSSE.—The Wisconsin Light & Power Company, of La Crosse, has placed orders with the Westinghouse Companies covering the entire equipment of a large light and power plant. Besides two alternating-current generators with an output of 400 kilowatts each, which will be driven by steam turbines, there are three vertical steam engines, one of which will be connected to a 25-k.w. direct-current generator. In addition, there will be installed two motor-generator sets, each consisting of a 7½-k.w. direct-current generator and a 15-h.p. induction motor, three 10-k.w. and three 15-k.w. transformers, one 6,600-volt 10-panel switchboard and one 220-volt arc-lamp panel, fifteen low-equivalent lighting arresters and choke coils, and 25,000 incandescent lamps with Edison bases.

CANADA.

OXFORD.—The electric light plant and many business places were totally destroyed by a recent fire.

NIAGARA FALLS, ONT.—The Ontario Power Company has awarded a contract to the Archbold-Brady Company, of Syracuse, N. Y., for the construction and erection of 200 steel towers for the double transmission line from the company's plant at Niagara Falls down the river and across to the American side, a distance of about six miles. The contract amounts to $50,000.

OTTAWA, ONT.—An important epoch in electrical development in Ontario has been marked by the action of the Railway Committee of the Provincial Legislature. A Government clause has been inserted in a bill retaining to the Government the right to transmit electricity from water powers to the municipalities. This step probably foreshadows an advanced policy on the part of the Government for the development of water resources in the interests of municipalities. Public ownership of public utilities seems to be the object in view.

ST. JOHN, N. B.—United States capitalists who make up the Electrico-Manganese Company are depositing $50,000 with the New Brunswick Government as evidence of good faith that they will develop the great water power of Grand Falls on the St. John River. Their project includes establishment of ferro-manganese mills, the operation by electricity of a railway from Campbellton to a point near the Maine border and transmission of electricity down the St. John River Valley for lighting and manufacturing. The expenditure is estimated at from $3,000,000 to $4,000,000. In the company are Barton E. Kingman, of New York, and Frederick Sayles, of Providence.

American Electrician.

Vol. XVII. New York, July, 1905. No. 7.

MODERN AUSTRIAN HYDRO-ELECTRIC GENERATING PLANT.

SOME FEATURES OF THE CENTRAL STATION IN ZWOLFMALGREIEN.

BY A. STEENS.

The conditions which had to be considered in the construction of the recently opened electric light and power plant at Zwölfmalgreien, a town near Bozen in the Tyrol, are of such a striking nature as to stamp the entire plant with a peculiar interest. The fundamental conception, dominating the entire undertaking, was that of combining an electric plant with water-works for the distribution of water for private consumption. Such a combination was in itself a guarantee for the cost of erection and running expenses, while promising highly favorable returns on the capital invested.

The town of Zwölfmalgreien had for a long time felt the need of a system for drinking-water distribution, as there were only three wells and a wooden aqueduct bringing water from the neighborhood of Bratenstein. The rising manufacturing interests of the place and the large and constantly growing number of tourists visiting it made a better domestic water service a necessity. The matter was investigated, and while studying it the requirements of the neighboring townships of Gries and Korneid were likewise taken into consideration. The committee in charge of the survey decided to harness the springs of the "Hals," in the Eggenthal, as well as those of the Ruselquelle and the Rameglerquelle, which furnish 50 litres of water per second, and to lay the water conduit through the Eggenthalerstrasse. But the committee was obliged to abandon the plan on account of the numerous difficulties encountered. A

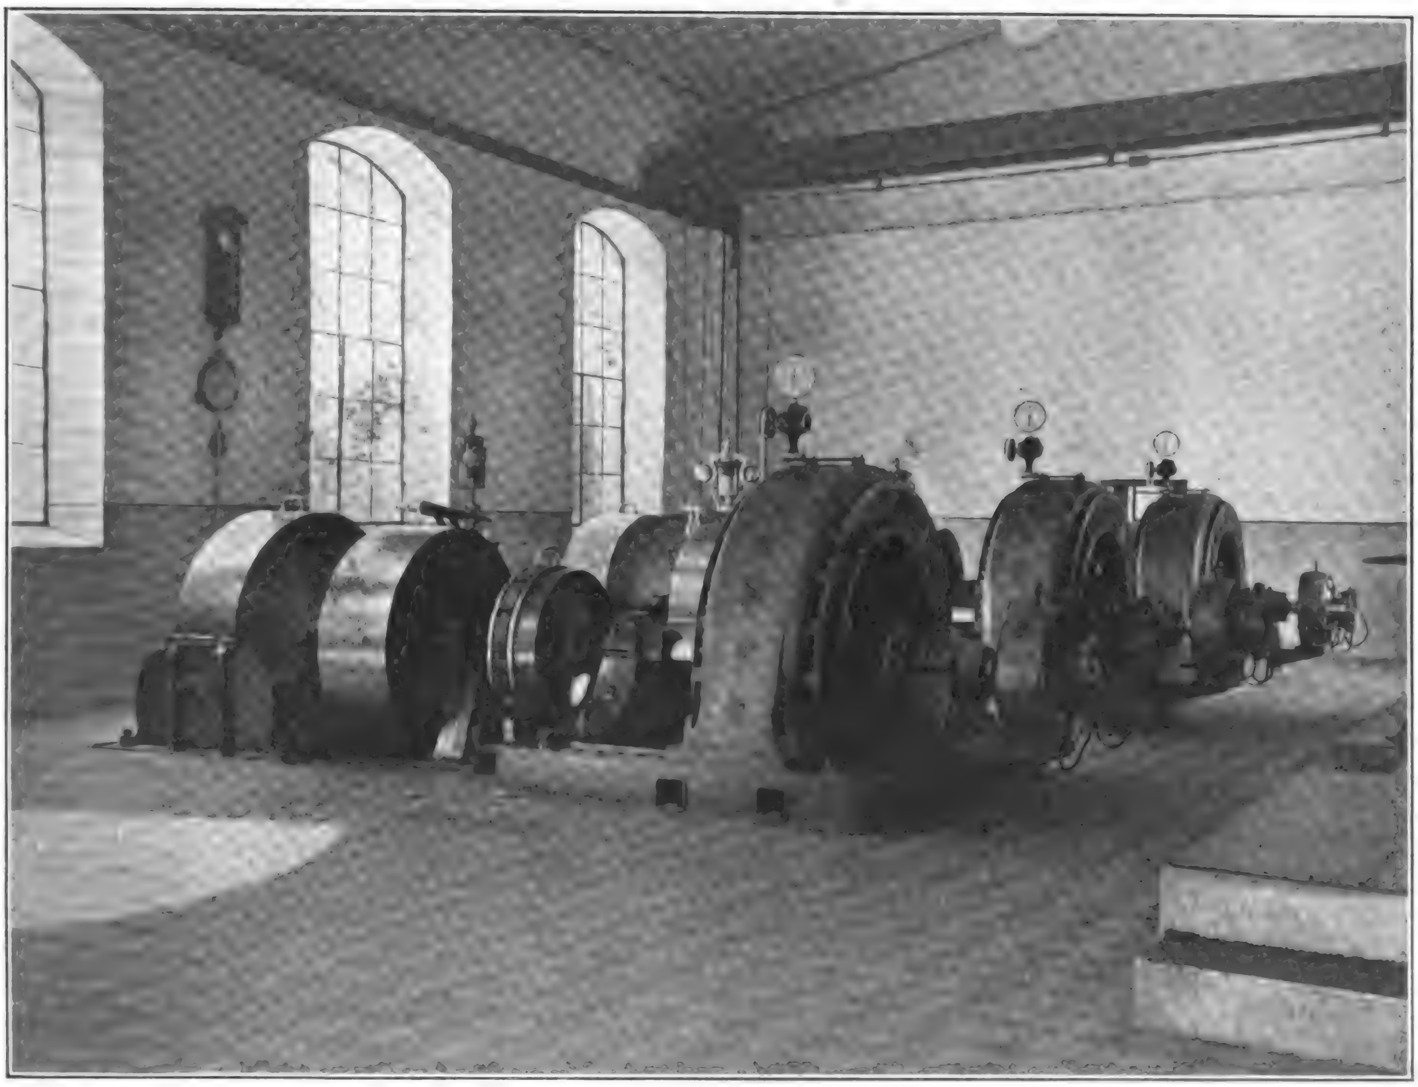

FIG. I.—INTERIOR VIEW OF THE HYDRO-ELECTRIC STATION AT ZWÖLFMALGREIEN,

choice of two alternatives was still left, one of which was an overhead pipe line suspended from the rocks and the building of an aqueduct, and the other the construction of an underground passageway or tunnel. The first alternative had to be abandoned on account of serious technical difficulties, and consequently the second plan, that of placing the supply conduits in an underground passageway or tunnel cut through the mountain, was resorted to.

In order to reduce the estimate for building a drinking-water supply system, the town decided to likewise carry out the plan which had been under consideration for a long time, viz.: the installation of an electric plant, and the use of the drinking-water supply tunnel for transmitting the hydraulic power which was to be supplied from the Eggenthalerbach. After an examination of the various plans, the one proposed by the Ateliers de Construction Oerlikon (Oerlikon Works) was adopted, and this firm was entrusted with the construction of the entire installation.

The hydraulic power is furnished by the Eggenthalerbach; this creek has its source at the foot of the Latemar group in the Dolomite mountain chain, is reinforced throughout its course by the waters from two other creeks, the Zangenbach and the Welschofenbach, and empties into the Eisack River near Kardaun. At their average height (220 millimetres) the flow of the waters of the Eggenthalerbach is about 2.32 metres. Gauge tests have shown that the minimum quantity of water was 600 litres per second. The terms of the contract allow of the taking of a maximum of 1000 litres of water per second from the creek.

The upper end of the water dam is 516.1 metres above the sea level, and 3.375 kilometres from the plant; it is constructed of masonry, with a total length of 60 metres and a width of 4.5 metres at the top, which latter is covered with boards which when damaged, may be easily replaced.

FIG. 2.—HYDRO-ELECTRIC STATION AT ZWÖLFMALGREIEN, SHOWING PIPE LINE.

The water flows through five openings at the intake proper, provided with gratings, each of which can be taken out separately, and is composed of gas pipes having a diameter of 50 millimetres.. The bottom of the collecting channel is made of concrete, and the side walls, which are partly built against the rocks, are constructed of masonry. The bottom of the collecting channel has been made lower than that of the main channel which it supplies for the purpose of preventing a part of the substances carried along by the water from being carried down into the tunnel, the result being that most of the rolling pebbles and other impurities carried along by the creek are deposited on the bottom of the collecting channel, whence they are from time to time removed by the opening of a sluice gate, which is 1 metre wide and 2.5 metres high and located in a prolongation of the collecting channel.

The passageway or tunnel, which is at a right angle to the collecting channel, is provided with a grating at the intake, the spaces between the bars of which are 15 millimetres. Two more sluice gates, 1 metre wide and 2.5 metres high, have been placed farther in the tunnel, and eight discharge sluice gates have been distributed along the entire length of the tunnel.

The tunnel runs for nearly its entire length through good rock (porphyry). Disintegrated rock has in a few isolated places been encountered, requiring at these points the construction of a lining of masonry. The water furnishing the motive power occupies a space of 1 sq. metre at the lower part of the tunnel, and a wooden flooring has been constructed above this flow of water, supported by the rails which were used during the boring of the tunnel. There is still a space of 1.6 metres above this flooring, so that it is possible to pass through the tunnel throughout its entire length. At the side of this flooring and supported by the same rails, is the drinking water conduit, with an inside diameter of 225 millimetres. The grade of the tunnel is 1.5 per thousand, and the water flows at a speed of 1 to 1.5 metres per second. At the lower end of the tunnel the water is discharged into a "water chamber" located at an altitude of 551 metres above the sea-level. This "water chamber," which is constructed entirely of concrete, is not intended to serve as a reservoir, but merely as an intermediary station between the supply tunnel and the hydraulic pressure pipe, which is the final water container. In order to remove the impurities which settle at the bottom of the "water chamber," a discharge sluice gate has been constructed at one of its sides. The entrance to the hydraulic pressure pipe is opposite the tunnel outlet, which latter may be closed by means of a gate. The pressure pipe has an air outlet located at the intake, which outlet allows the air to escape when the pipe is filled under pressure.

The pipe is constructed entirely of steel

FIG. 3.—TRANSFORMER TURRET.

plate; it is 416.4 metres in length, and at 11 different places along its length the thicknesses of the pipe walls are progressively increased, so that while the steel plates measure only 5 millimetres at the top, they have a thickness of 15 millimetres in the last section, at the lower end. The inside diameter of the pipe is 900 millimetres and each length is 6 metres; the longitudinal seams are fastened by two rows of rivets, with a single row for joining the ends. The flanges, with the exception of those of the lowest part (which are of cast steel), are of forged iron. The pipe, at regular intervals, rests free on cast-iron supports, solidly fastened to concrete blocks. Care has been taken to solidly anchor the conduit at the four bends which occur along its entire length; it is, furthermore, provided with expansion joints at three places and it terminates at the lower end in a trench 33 metres long, cut out of the mountain rock immediately alongside the walls of the power plant. The gross fall that may be used for power purposes (measured down to the turbine shaft), is 210 metres, while the net fall is 208 metres. The maximum speed of the water is 1.42 metres per second; this maximum speed is obtained when all the power at hand (2000 horsepower) is used, or, in other words, when all four turbines are in operation.

The central power house is located at the entrance of the Eggen valley, near Kardaun, at the place called Florkeller, on the left bank of the creek known as the Eggenthalerbach, and at an altitude of 300 metres above sea-level. It is located about 700 metres up-stream above the mouth of the last named creek, where it flows into the Eisack river and is about 4 kilometres from the Bozen railway station.

The plant comprises a main building with an area of 374.5 sq. metres and contains the large dynamo room (275 sq. metres). There is, moreover, an annex, a two-story building, the lower floor of which is occupied as an instrument room (25.4 sq. metres), while the second story is used as an office. The repair shop has been located in the basement on the side toward the creek, covering an area of 29.55 sq. metres. A staircase connects the dynamo room with the office. The wall of the latter nearest the dynamo room has a large window, allowing a full view of the machinery from the second story. The repair shop is likewise directly connected with the dynamo room by means of a staircase. The building has concrete floor and walls of masonry

FIG. 4.—SWITCH HOUSE FOR CHANGING FROM UNDERGROUND TO OVERHEAD DISTRIBUTION.

(porphyry). The roof is supported by an iron framing to which a wire netting is fastened, holding the inner plastering. The floor of the dynamo room is covered with cement slabs. A platform has been erected in front of the switchboard, at a height of 400 millimetres above the floor of the dynamo room. This platform is constructed of a block of cement, covered with linoleum, and a rubber matting is provided to insure perfect insulation. The floor of the apparatus room is of concrete and likewise covered with rubber matting. A traveling crane of 7.5 tons capacity is installed in the dynamo room, capable of handling any one of the five hydro-electric units. As soon as the installation shall have been entirely completed there will be four hydro-electric units in active service, while a fifth will be held in reserve.

The works are lighted by three 15-ampere arc lights, connected in series; 8 incandescent lamps fastened on brackets in groups of two, and two additional incandescent lamps for lighting the switchboard. In addition to the above, kerosene lamps have been furnished for use, should the electric current fail. The instrument room is lighted by two incandescent lamps.

The ditch for the water supply conduit is outside, and runs along the southern frontage of the building. This ditch, which extends the entire length of the building, is lined with concrete and is two metres wide, with a depth of 1.7 metres.

The turbines, as well as the hydraulic pressure piping, the iron parts of the water intake and of the water chamber, were furnished by J. Ig. Rusch. of Dornzirn, Voralberg, Austria. The lower part of the hydraulic service pipe in the above-mentioned ditch contains the water distributing device and the five conical outlets for conveying the water to the turbines. Each of these outlets is provided with a high pressure slide-valve, and in front of the first there is an air chamber. The distributing device is provided with four safety valves and a cleaning-out valve at the lower end. The latter has a bell-shaped protector for the purpose of sufficiently diminishing the water velocity to prevent damage to the concrete lining of the ditch.

The turbines are constructed for a net fall of 208 metres. They use 226 litres of water per second and produce 500 horse-power when running at the rate of 500 r.p.m., which corresponds to 80 per cent of the full power guaranteed by the builder. They are of the Rusch "spoon" type of construction.

After passing through a controlling valve the water enters the turbine chamber and from there passes to the distributor, which consists of phosphor-bronze troughs. Each trough may be separately closed by a cog crown wheel valve, which is likewise constructed of phosphor-bronze. This valve is controlled by means of a hand wheel placed on the platform in front of the switchboard. The spoons or buckets of the turbine wheel are of white metal and may easily be replaced when damaged. The controlling valve in front of the turbine chamber, which automatically regulates the inflow of the water, is moved by an hydraulic relay operated by a very sensitive ball governor.

FIG. 5—TRANSFORMER TURRET FOR HIGH-TENSION CURRENT.

The water required for operating the hydraulic relay is taken from the service pipe and passes through a double filter before reaching the relay. Any jerky operation of the governor is slowed down by an oil regulator, and further regulation is secured by safety valves connected with the above-mentioned distributing device, placed alongside of a 3250-kilogram fly-wheel, 1450 millimetres in diameter. As soon as the water pressure rises above the normal point these safety valves allow a certain quantity of water to escape. An air chamber placed in the front part of the first neck of the distributing device prevents water hammering.

Direct-driven speed gauges from the dynamo shafts are provided for noting the generator speeds. According to the builder's guarantee, whenever sudden changes in the load take place amounting to as much as 50 per cent the speed variations must not exceed 3 per cent, more or less, and for load changes amounting to 100 per cent the speed must show a minimum variation of 6 per cent, more or less. Tests have been made for the purpose of determining the regulating quality of the apparatus. The load was varied by the use of water resistances, and the tests showed that when suddenly changing from a load of 380 horse-power to no load the speed of the turbine varied only 2½ per cent from that which it made with a 380-h.p. load. A comparison between a turbine running without a load at full head and a turbine running with a full load could be easily and safely made.

The generators, which have a capacity of 500 horse-power each, were furnished by the Oerlikon Works. At a speed of 500 revolutions per minute they produce a 3600-volt, three-phase current of 50 cycles. The power factor is 0.8. The generators are coupled to the turbines through elastic coupling flanges.

The armature space measures 1400 millimetres. The armature, which has 72 slots, is provided with 18 coils, each of which is composed of 17 two-wire windings of a diameter of 04.0 to 04.6 millimetres. These coils are wound to gauge. The diameter of the rotor is 1390 millimetres. The 12 conductor coils which are connected in series are each composed of forty 3x33-millimetre, copper-tape windings for the field. The different windings are insulated from each other by means of a 0.5-millimetre asbestos layer.

The exciters are keyed direct to the generator shafts and produce a current of 200 amperes. They are provided with 12 carbon brushes, 24 by 16 millimetres in size.

The conductors connecting the generators and the exciters with the switchboard are for a part of their total length enclosed in a conduit sunk in the floor of the dynamo room and covered with sheet iron. On leaving the conduit they run through a channel in the basement. The main conductors are fastened to double-petticoat, porcelain insulators on iron supports. The conductors for the exciting current are fastened to small cylindrical insulators.

The controlling apparatus, fuses, bus-bars, etc., are placed in a room separated from the dynamo room by the switchboard, which is constructed of white marble panels enclosed in a channel iron frame. Below the marble slabs the partition is constructed of perforated sheet iron, which allows of a continuous ventilation for the switchboard.

Of the five panels which make up the board, the first three, counting from the left, are for the three generators already installed. Each slab is provided with an ammeter for measuring the primary current of the generator, another ammeter for the exciting current, the handle for the three-pole circuit-breaker and the hand-wheel for the regulator.

There being two bus-bar systems, one for the light and the other for the power circuit, the fourth panel is provided with an ammeter and a voltmeter for each of the bus-bar systems. A common voltmeter with switch has been provided for measuring the phase tension of the different generators. All the voltmeters have been so mounted that they may be turned. The fourth panel has placed alongside of synchronizing lamps, the lever of a three-pole circuit-breaker, by means of which the two bus-bar systems may be connected in parallel.

The switchboard room is divided in two parts by an aisle enclosed on both sides by an insulated railing. On the side nearest to the dynamo room there are for each dynamo a three-pole circuit-breaker, three single-pole, high-tension fuse switches, the switchboard transformer with two fuses in the primary circuit and the regulating resistances.

In the opposite part have been placed aluminum bus-bars for the light service as well as those for the power service, each of these being provided with a fuse. Moreover, there is a three-pole switch for each generator, which arrangement permits of switching the generators either on the light or on the power circuit. In the same part of the switchboard room is placed a 7-kilovolt-ampere transformer furnishing the current for the lighting of the plant as well as for the neighboring dwellings.

Beyond the fuses the conductors run upwards through two holes in the ceiling until they reach the inside of the roof where the lightning arresters are placed, grounded by means of 6 millimetre copper wires. At the place where they pass through the partition the wires of the lighting and power circuits run through glass tubes.

The two high-voltage systems, that form the lighting circuit as well as the power circuit, are partly underground.

The overhead conductors, both for lighting and power, are composed of 3 semi-hard copper wires 7 millimetres in diameter, follow at the start the left bank of the Eggenthalerbach to Ganserhof, where there is a transformer. Here it passes over the creek and follows it bank to where it flows into the Eisack, which it crosses at this point, the distance between the supports on both banks being 45 metres. The overhead line, which is 800 metres in length, ends 90 metres farther on a turret. The weight of the copper used for the lines is 1700 kilograms and the number of poles is 26. These poles, made of larch wood, measure 15 metres in height and have a diameter of 18 to 26 centimetres at the top. They are planted in the earth to a depth of 16 to 18 metres.

Each pole is surmounted by a lightning arrester, grounded by means of a 6-millimetre copper wire, at the base of which is a 400 to 450-millimetre ground plate. In order to make sure that the lightning arresters will work even in case of a defect in one of the copper grounding wires, they have all been connected by means of a zinc-covered wire 4.5 millimetres in diameter.

The above mentioned turret is erected for the purpose of changing the overhead line into an underground one. It is square built, of masonry, and has a height of 6.75 metres. The sides of the inside square measures 1.9 metres, and the walls are 3500 millimetres thick. There is an iron frame in the inside, which supports the Thomson lightning arresters, the induction lightning arresters with their induction coil and the three single-pole, high voltage fuses for each circuit. In the lower part of the turret are the connecting parts for the cables.

The cables are paper insulated, lead enclosed and covered with two layers of ribbon steel and tarred jute. The lighting and the power cables are placed side by side in a bed of sand, and are covered with porphyry slabs under a 700 millimetre layer of earth. 5080.1 metres of 3x50 square millimetre cable are used, as well as 3288.4 metres 3x25 square millimetre and 1721.7 metres 3x15 square millimetre cable, making a total length of 10,090.2 metres of cable. For the underground system, moreover, 53 joint boxes and 26 connection boxes have been used.

The transformers have been placed in cylindrical turrets constructed of forged sheet iron, anchored in a concrete block. There are two sizes of turrets, viz.: Those from which the secondary conductors start out in the shape of overhead lines, and which measure 6 metres in height, and those from which run the secondary conduc-

FIG. 6.—INCANDESCENT LAMP POST AT GRIES.

FIG. 7.—OVERHEAD SECONDARY LINES AND STREET LAMP.

tors in the form of cables, which are only 4 metres high. According to the number of high voltage fuses which must be enclosed in the turrets, they have a diameter of either 1422 millimetres or 1600 millimetres. The frame supporting the apparatus is separately anchored in the concrete and is, furthermore, fastened to the turret wall by means of screws. Each turret has three doors, one of which leads to the transformers, the second to the high voltage apparatus and the third to the low voltage devices. The cables, which are provided with a connection box, enter the turret on the side where the high voltage apparatus is placed. Both the lighting and power cables leave the turret on the same side, where the high voltage fuses required for the line, as well as the tree-pole, high tension fuses for the transformers are likewise to be found. These latter are located between the high and low voltage sides. Whenever two transformers are found in the same turret, one has been placed above the other. All the transformers are grounded by a 6 millimetre copper conductor anchored at its base in a 500 by 500 millimetre ground plate. On the low voltage side, on a white marble slab are placed the three-pole circuit breakers for the low voltage system, as well as the fuses for the secondary transformer coils and for the secondary circuit. The same marble slab supports the circuit breakers for the public lighting service.

Transformers are provided for the lighting circuit only. The high voltage currents pass through the transformer turrets for the purpose of making it possible, in case of accident to the high voltage lighting system, to feed the transformers from the power system.

At Zwölfmalgreien there are seven 6 metre and two 4 metre, and at Fries three 4 metre turrets. Moreover, a room of the Hotel Stigel at Zwölfmalgreien, built of masonry, is used as a transforming station.

In only one of the several stations does the primary current enter through an overhead line. The transformers reduce the lighting current to a voltage of 150. All the motors of more than two horse-power have been switched on to transformers, which are gradually being installed in accordance with actual requirements. At present the transformers feeding the lighting circuit are twelve in number, representing a total of 137.5 kilowatts.

At those localities where the consumption of electricity is very large, and where the esthetic question is more important than the cost, underground conduits are being used. At other points the secondary conducts are strung overhead. The low voltage cables, as far as their construction and installation are concerned, are identical to those for high voltage.

3138 metres of cable have been laid, ranging in size from 3x50 square millimetres to 3x35, 3x20 down to 3x10 square millimetres. The overhead conducts are 5.6 and 7 millimetres in diameter. They are supported on porcelain double petticoat insulators, fastened to wooden poles of a height of 10 metres. These poles carry a four millimetre wire for the incandescent lamps supplied for the public lighting service, as well as two, or even four wires of the same size for the arc lights. All low voltage conductors are of semi-hard copper.

The poles are surmounted by a sheet iron cap and a point. All these points are connected by means of a 3.5 millimetre iron wire. At distances of 3 or 4 poles this wire is grounded through a conductor of the same metal and diameter, soldered to a zinced iron plate.

The arc lights for the public lighting circuit are supported on lamp posts or suspended from steel wires strung across the streets. These lamp posts are thicker at the bottom than at the top, made in one piece and provided with a pedestal, cast iron rosettes and a forged iron arm. The height of the lamp above the street level is 6 metres. The lamp uses 15 amperes and gives 800 candle-power. They are connected in series, in groups of 3 or 4.

All the incandescent lamps for the public lighting service are 32 candle-power. They are either fastened to the poles, to the houses, or (at Gries) to lamp posts. The supporting arms for the incandescent lamps are forged iron and 750 millimetres long. They are provided with a conical reflector and a protecting globe hermetically closed. The height of the lamps above the street level is 4 metres.

as well as for power purposes is paid for either in an annual sum for each lamp or each horse-power, or at the rate of consumption as indicated by the meter.

More or less important rebates are allowed when this last method of payment is chosen, which rebates vary according to the size of the installation. The various localities to be lighted have been classified to facilitate the figuring of prices in lump annual sums. An annual rental is paid for the use of the metre.

INDIVIDUAL VS. BELT DRIVE IN ELECTRICALLY OPERATED SHOPS.

BY PUTNAM A. BATES.

Very few shop managers will dispute the question or the desirability of driving their machinery by electricity, but when a canvass is made of all the machine shops and factories throughout the entire country, one cannot help but be impressed with the fact that the electrically driven shop is as yet greatly in the minority, and even in the establishments where the electric motor is used, the electric idea has not been carried anywhere near far enough to permit of the full advantages being received from this method of power transmission.

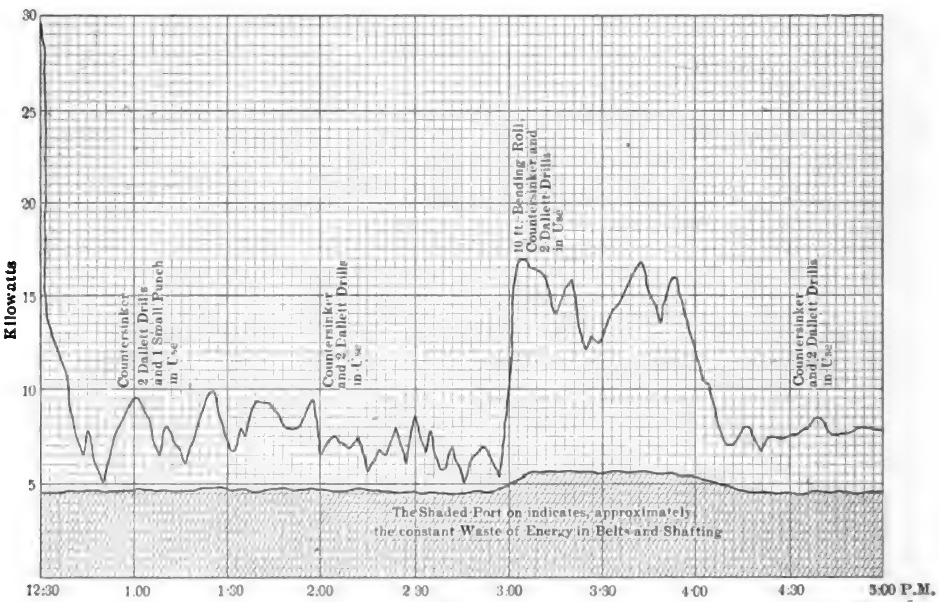

FIG. I.—LOAD DIAGRAM SHOWING POWER CONSUMED BY A 25-H.P. MOTOR IN BOILER SHOP.

As mentioned above, the circuit breakers and the fuses for the public lighting circuit are placed in the transformer turrets. At the present time 23 arc lights and 60 incandescent lamps have been installed at Zwölfmalgreien for the public lighting service. Gries has been supplied with 2 arc lights and 35 incandescent lamps (all installed on lamp posts). At the time the station was started 2000 lamps were used in the private lighting service, the lamps being 5 to 25 candle power.

The works employ, in addition to a general manager, a chief engineer, two engineers, a workman for the plant and a lineman, a box trimmer and a workman for the lighting circuit. The works are run day and night. The current for lighting

What is the reason for this condition? Is it that the electric motor has not yet demonstrated its worth for general power purposes? These are questions which naturally suggest themselves when one has occasion to visit a manufacturing establishment or machine shop where power is still transmitted by belting and shafting, rope drive or other mechanical means.

A consideration of these two questions and an analysis of the situation which suggests them may be at this time of some interest to those whose fortune or misfortune it is to have to utilize power in accomplishing the ends which they are daily striving for.

During the past fifteen years there has naturally been a great deal of progress and

improvement made in the methods of applying the electric motor to machinery, so that the energy which is transmitted electrically to the motor may be applied by the latter directly to the device by which the energy is to be utilized. There has also been a vast improvement in the construction of the electric motor itself, and owing to the large number of manufacturing concerns now making motors, the prices have been brought down by commercial competition to a point where the cost of electrical apparatus is within the reach of all.

In a number of the establishments where individual electric drive of machinery has been adopted, it has been demonstrated that the first cost of the electric motors and their accompanying controllers or starting boxes is no more than that for the equivalent shafting, hangers, belting and other paraphernalia plus the labor of properly setting them in place. In a new building, therefore, the installation of anything but individual electric drive, except possibly in some instance where peculiarly special conditions prevail, indicates a lack of familiarity with the full advantages which are to be derived from this method. In fact, if the average shop owner would only take the trouble to find out, he would discover that even in an old shop where power is being transmitted and applied indirectly by the usual mechanical methods, the actual saving to him in power consumed, and the advantages of increased rate of product output at lower cost which the direct electrical method makes possible, are many times more than sufficient to justify the bother and expense of the change.

It has been the writer's observation that in many instances where motors have been installed thorough consideration has not been given to the question of the correct size and type of motor for the actual conditions under which the machine which it will drive will be obliged to operate, the result being that the electrical equipment is either unnecessarily large and costly, or too small for the work, which means constant trouble with the motor and its controlling devices.

A very usual mistake which is so often committed in establishments where the electrical equipments have not been thoroughly laid out and planned before hand is illustrated by the following example: A section of a boiler shop contains, we will say, an edge planer, a heavy shears, three punches of different sizes and two plate bending rolls, one an 8-ft. and the other a 10-ft. bending roll. In this installation the edge planer and the shears, each of which is located somewhat distant from the other tools, have been equipped with individual motors. The remaining tools just mentioned, however, are located in a group together, and are all driven through shafting and belting by one 25-h.p. motor. . This motor is placed directly over the countershaft to which it is connected by a 14-inch belt. The countershaft pulley is about 30 inches in diameter and the distance between shaft centres about 7 feet. The countershaft is connected by a 24-in. belt to the main shaft, which is in turn located directly over the motor, thus giving two belt drives in a vertical plane.

From the main shaft the three punches are belt-driven directly, the largest punch being so located that there is no place for its belt to hang if removed from its driving pulley, hence the punch must be driven all the time whether doing work or not.

The two smaller punches are each driven by a quarter turn belt from the main shaft. The method employed for harnessing these two machines for their work may be described as that of "kicking" the belt off and "prying" it on with a "stick." Anyone who has seen this method used, especially in a case where "the belt sticks a bit," knows the time which is lost by the operator of the tool and the attendant of the next adjoining machine in "getting the thing started."

The two plate bending rolls are each belt-driven from a separate jack shaft placed directly over the rolls, and in turn belt-driven by the main shaft. In addition to the above the main shaft drives five portable drills and two countersinkers, all belt connected.

The appearance of this equipment is, as one may easily imagine, a mass of overhead construction put in every which way in order to support the shafting and belts, and without any apparent consideration of the valuable light and space which are thus shut off.

This is an example of a shop "electrically driven,' and yet how it does grate on an electrical man's nerves to see such a sight and hear of its being put in that class. To be sure it is electric drive, but what a pity it is that the electrical idea had not been thoroughly worked out and properly applied.

It may be interesting to discuss some of the details of this particular shop equipment.

FIG. 2.—SHOP IN WHICH THE ADVANTAGES OF ELECTRIC DRIVE HAVE ONLY BEEN PARTLY SECURED.

To demonstrate the saving in power consumption alone which can be accomplished by individually driving the machines, some tests were made on these motors installed in this boiler shop. These tests were made under normal conditions of operation.

A test of the 5-h.p. motor driving the shear by means of a belt running on the fly-wheel gave the following results:

Volts.	Amp.	Prob. HP.	Remarks.
230	21	5.85	Starting from rest.
230	4-5½	.86-1.2	Shear running free.
230	11-13	2.7-3.2	Cutting, ¼-in. iron full width of shear.
230	8	1.9	Cutting ½-in. iron 1¼-in. wide.

This tool is in use only at rather infrequent intervals, and being individually driven the motor is shut down at all times except when the shear is in operation, and therefore no power is uselessly consumed.

The motor driving this shear is placed on a bracket on the wall and is belted with seven feet between shaft centres to the fly-wheel of the shear, the diameter of the fly-wheel being 64½ inches. The connection between the motor and its tool is so bad in this case that in order to start the tool the operator must perform with his hand the duty of an idler pulley or else "the motor will not take hold of the belt," which is not an unnatural way for the motor to behave under the circumstances. A glance at the burned condition of the starter of this motor tells the story.

A test of the 10-h.p. motor, driving the edge planer by means of a countershaft and belts, gave the following results:

Volts.	Amp.	Prob. HP.	Remarks.
240	46	12.6	Starting from rest.
240	15	3.38	Planer running free.
240	35-40	9-10.3	1/16-in. cut from 9/16-in. iron plate.
240	30	7.7	Reverse of planer.
240	25-30	6.4-7.7	Normal cut from 9/16-in. plate.

This tool is in use for about one-half to two-thirds of the time, it being entirely shut down while the work is being shifted. As in the case of the shear this is possible because the tool is individually driven.

The test of the 25-h.p. motor which drives the several lines and countershafts in the boiler shop, from which all of the tools, with the exception of the shear, derive their power, was continued throughout the afternoon from half past twelve until five o'clock. The results of this test are shown in the load curve diagram herewith.

A series of readings were taken at a time when no power was being used except for driving the shafting, two portable drills and a countersinker. These three drills were being used intermittently and probably did not require over one kilowatt of power as an average during the time when the readings were made. A reading of both current and voltage was taken every fifteen seconds for three minutes. An average of these readings showed the current consumption during this time to be 22.7 amperes at 238 volts, or 5.4 kilowatts. Deducting the remaining 4.4 kilowatts represents the power which is continually being consumed to drive the belting and shafting in this shop, not including several small counter-

shafts which were not in motion at the time.

This power at five cents per kilowatt hour represents a yearly waste of $660.00 most, if not all of which, could be avoided by the use of individual motor drive.

It appears, therefore, that the application of individual drive in this shop would not only improve the general conditions and increase the daily output, but the actual money saving in the cost of power consumed would pay good returns on the investment which such an equipment would require.

The introduction of electrical apparatus in the equipment of shops without fully knowing the reason for doing so is probably the explanation for the easily avoidable mistakes which the above description illustrates, and which it will be found is too often made by those shop managers who will not stop to find out exactly what sort of electrical equipment they will need and the best way of installing it. The shop man who is willing to "put his motors anywhere" is not worthy of using such apparatus at all.

FIG. 3.—SHOP IN WHICH ELECTRIC IDEA HAS NOT BEEN FULLY CARRIED OUT.

A systematic study of all of the detailed problems involved in the application of electricity to a given shop is a work in itself. Those shops and factories which have not as yet been equipped will do well to make a thorough investigation of their real needs before actually ordering their equipments.

There is no question but that the electric motor has proven its worth and many times over, and if those who use power were to appreciate this more than they usually do, they would be better off. One great difficulty, however, which everyone interested in the greater use of electrical apparatus has to continually meet, is the element of human nature.

The advantages of individual motor drive have been demonstrated for over fifteen years, and yet to-day one will hear people talk of it as though it were a new thing. Some will probably continue in blissful ignorance for years to come, while others will proceed to install their equipments without knowning how or why; but those who wish to obtain the full benefits will work out the details so they may know exactly what returns they may expect.

The accompanying half-tone engravings show portions of the shop herein described, and illustrates how electric motors may be in use and yet the full benefits of electric operation not be obtained because the electric idea has not been carried far enough.

BOILER FEED APPARATUS.

BY CHARLES L. HUBBARD.

Boilers are usually fed by small direct-acting steam pumps, although power pumps driven by the engine are sometimes used. The former require a large amount of steam in proportion to the power delivered, but this is small in comparison with that generated by the boilers, and is offset by certain advantages which this type of pump has over the power pump. The speed of the steam pump may be easily regulated to furnish the required amount of feed-water under varying conditions, while with the power pump it is necessary to run it at a constant speed and allow the excess of water to flow back into the suction pipe through a relief valve.

The principal objection to the *piston* pump is the difficulty experienced in keeping the piston tight, and of detecting leaks when they occur. On this account the *plunger* pump is often preferred. The advantage of this form over the piston is the ease with which it is kept tight under high pressures, and with gritty liquids the wear is taken by the bushing which is more easily and cheaply replaced than a cylinder lining. In order to examine or repack either a piston or single-plunger pump it is necessary to dismantle it. The two-plunger pump with outside yoke can be repacked from the outside, and any leakage may at once be detected. When two cylinders are placed side by side and discharged into a common delivery pipe it is called a duplex pump.

Theoretically, the quantity of water delivered by a pump in a given time is equal to "area of plunger × length of stroke × number of strokes."

Actually there is a certain amount of leakage around the plunger and through the valves, called "slip." This brings the actual capacity down to about 80 per cent of the theoretical in good pumps of medium size.

The following table gives the capacities of standard duplex feed-pumps for various speeds. These figures are based on 30 pounds of water per hour per boiler horse-power and 80 per cent slip. The speed of a pump is often expressed in piston speed instead of strokes per minute. This should not exceed 100 feet per minute as a maximus, and 50 feet or less for continuous working pumps is better.

Size of Pump.	30 strokes per min. B'l'r H.P.	45 strokes per min. B'l'r H.P.	60 strokes per min. B'l'r H.P.
2"x1⅛"x2¾"	7	10	13
3"x1¾"x3"	24	36	48
4½"x2¾"x4"	77	116	154
5¼"x3½"x5"	160	240	320
6"x4"x6"	250	376	502
7½"x4½"x6"	320	480	640

The propositions given in the table are for moderate to high steam pressures. If it is desired to operate the pump at a steam pressure much less than 20 pounds it should be provided with larger steam cylinders, depending upon the pressure at which it is desired to run it. In laying out a boiler plant it is advisable to use two pumps of such capacity that either of them running at a speed of 50 or 60 strokes per minute will deliver the maximum quantity of water required under ordinary conditions. This makes easy work for the two running together and allows a reserve pump.

The following data relating to water will be found useful in making calculations for the capacity of pumps:

Cubic feet × 62 = pounds.
Pounds ÷ 62 = cubic feet.
Gallons × 8.33 = pounds.
Pounds × 0.12 = gallons.
Cubic feet × 7.5 = gallons.
Gallons × 0.134 = cubic feet.

These figures will vary slightly for different temperatures, but are sufficiently accurate for ordinary use. The boiler power required for running a pump is computed in a similar manner to that required for a steam engine.

The rating or capacity of a pump, however, is usually expressed in gallons of water per minute raised to a given height, instead of in horse-power as in the case of an engine. The weight of water in pounds per minute multiplied by the height in feet, to which it is raised, divided by 33,000, will give the useful or delivered work of the pump in horse-power.

The friction of the moving parts of a pump and of the water flowing through the passages and valves is so great under ordinary working conditions that not much more than 50 per cent of the indicated horse-power of the steam cylinders is utilized in doing useful work.

This calls for a large consumption of steam in proportion to the work done, and from 80 to 120 pounds of steam per delivered horse-power is common in pumps of this class. The higher figure should be used for small boiler feed pumps, while 100 pounds may be taken as a fair average for pumps of moderate size.

The "head" against which a pump works is the vertical distance between the surface of the water in the suction reservoir and that in the discharge reservoir. If the pump is delivering against a pressure, as in feeding a boiler, the pressure is reduced to "head" in feet by dividing the pressure per square inch by 0.43.

Denver Convention of the National Electric Light Association

The twenty-eighth convention of the National Electric Light Association was held at the Brown Palace Hotel, Denver, Colorado, June 6, 7 and 8. The welcoming address was made by Mayor Speer, immediately after which Mr. E. H. Davis delivered his presidential address. Mr. Davis referred to the great and constant menace to electric light interests in the unwise and burdensome legislation by municipalities and states. State commissions, he said, are not altogether lacking in good features; but the association should make suggestions when laws affecting electric lighting interests come up for enactment. The appointment of a standing legislative committee was recommended. The president favored state associations for protective work and noted approvingly the proposal of the Association of Licensed Manufacturers of Incandescent Lamps to appropriate $10,000 for the purpose of cooperating effectively with central stations to increase by advertising and soliciting the sale of lamps and current. He also recommended the appointment of a committee to report on the proper method of grounding secondaries, and the continuance of the committee on steam turbines.

The presidential address was referred to a committee consisting of Messrs. L. A. Ferguson, F. W. Frueauff, George R. Stetson, Samuel Scovill and S. T. Carnes, who submitted the action of the committee at the final session of the convention. The recommendation as to the appointment of a standing committee on legislation was endorsed, and it was recommended that this very important matter be given immediate and fullest consideration of the executive committee. The suggestion for the encouragement of state and sectional organizations and cooperation with the proposed committee of legislation with those bodies was heartily approved. Following the submittal of the report, a resolution was adopted authorizing the expenditure during the coming year of a sum not to exceed $500 for such electrical tests as are thought advisable.

Brief abstracts of the papers presented, together with the discussions, follow:

Automatic Synchronizing of Generators and Rotaries.

This paper was presented by Mr. Paul Mac Gahan. The first improvement in synchronizing devices over the well-known phasing lamps was found in the "synchroscope," an instrument that rotated a pointer in synchronism with the difference in speeds of the machines. This instrument gives perfect indications of the phase relation between the machines at any instant and also indicates whether the speed of the incoming machine is too slow or too fast. It does not, however, make allowance for the time required to close the coupling switch. One of the best known of the early attempts at producing an automatic coupling device was embodied in the Pearson synchronizer. This device consisted of two controlling magnets mounted in the same case. One magnet was equipped with a time element which allowed it to close its contact when the difference in speed was small enough, and the other magnet would complete the switch-closing circuit when the machines were in exact synchronism. The author described in detail the new Westinghouse auto-synchronizer, and stated that it is a great advance in the handling of alternating-current generators and rotaries. In discussing the application of the device he remarked that an automatic synchronizer would be particularly desirable in the operation of large electric railway systems. When accidents occur which entirely shut down one or all substations it is exceedingly important to be able to start up with the least possible delay. If alternating-current starting motors are used and an automatic synchronizer is installed for each rotary, in order to start the substations it would only be necessary to throw in all the starting motors as quickly as possible and leave the rest to the automatic synchronizers.

Rotary Converters and Motor-Generators.

In discussing the means for the conversion of alternating into direct current, Mr. Louis E. Bogen stated in his paper that in this country only the rotary converter and the motor-generator are extensively employed, although the vapor rectifier possesses admirable qualities for this purpose. The disadvantage with the 25-cycle rotary resides in the low speed at which it must be run for low voltages in order to have a commutator of reasonable size. The design of the 60-cycle rotary is limited to such a narrow choice of dimensions as to be almost fixed, and it is better adapted to lower than to higher voltages. In response to a demand for something better than the 60-cycle rotary, there has been used in Europe a special form of double machine, composed of an induction motor to the secondary of which the collector rings of a direct-driven rotary converter are connected. The frequency applied to the induction motor is 60 cycles, so that if the motor revolves at one-half synchronous speed, 30-cycle e.m.f. will be impressed upon the converter proper. The paper described the various methods of starting rotary converters, and called attention to the necessity of properly adjusting the field strength to eliminate wattless currents, and mentions the use of reactance for assisting in parallel operation and for preventing hunting. The commercial forms of motor-generator sets were stated to be: (1), the combination of an induction motor and a direct-current generator; (2), a synchronous machine and a direct-current machine, and (3), two alternating-current machines coupled together for the purpose of changing the frequency in a system. For small motor-generators, the induction motor-driven set has numerous characteristics in its favor, but for larger sets the combination of a synchronous machine and a direct-current machine has a great many points in its favor in spite of the necessary auxiliaries. In operating a frequency changer in parallel with either another frequency changer or with a generator on the high-cycle end, there is but one way to connect the high-cycle end in parallel with the other unit. If the other unit happens to be of the same capacity and characteristics, the excitation of the generator end of the frequency changer must be the same as that of the unit with which it is to be brought in parallel, because after it is connected in a parallel a change in the excitation of either the motor or the generator will produce nothing but an interchange of wattless currents between the sets.

In the discussion which followed Mr. Clarence Renshaw, of Pittsburg, said that while it is difficult to design 60-cycle rotaries for high voltages, yet by proper skill such machines can be designed which operate entirely satisfactorily for direct-current voltages of 500 or even 600. He pointed out the very important advantage which the rotary possesses through its effect on line regulation. By proper adjustment a converter can be made to send a lagging current on the line or a leading current If induction motor-generator sets were used for operating railway load, a heavy draft of current would affect the voltage on the entire system, and when the cars let go the voltage of the system would rise. Rotary converters give a leading current on heavy load which tends to counteract the drop on the system, and when the cars let go the rotary gives a lagging current which tends to keep down the sudden jump of voltage which would otherwise occur. A motor-generator set driven by a synchronous motor would have the same effect. Mr. Alex. Dow, of Detroit, contended that distinction should be made between the apparatus discussed, as employed for railway or lighting service. In railway service it is possible to compound the rotary with the line to get the excellent results pointed out, but in lighting service, in which variations of voltage that are normal in railway work connot be tolerated, the conditions differ. Transformers for the rotary must be supplemented by regulating devices to give the necessary range of voltage control. In some recent stations the rotary equipment is both more complicated and more expensive than the motor-generator equipment. For lighting service the motor-generator under American conditions has very many advantages, while for railway service the rotary, even if it be the 60-cycle rotary, justifies its existence completely.

Series Alternating-Current Motors for Industrial Work.

This paper, by Mr. Clarence Renshaw, after discussing the constant speed characteristics of the induction motor and outlining the conditions under which a motor

possessing the speed-torque characteristics of the direct-current series is required, described a type of series alternating-current motor for both 25 and 60-cycle circuits which the Westinghouse Electric & Manufacturing Company has developed and placed on the market for industrial service. The motor is of the commutator type and is provided with an auxiliary field winding which is placed in slots in the pole pieces. The machine is a compensated motor similar in performance to the alternating-current railway motor.

A New Type of Single-Phase, Alternating-Current Motor for Elevator Work.

After having outlined the advantages of operating elevators by electric motors and having pointed out the limitations of the polyphase induction motor, Mr. S. Percy Cole described a type of motor which affords practically all of the desirable characteristics of the direct-current motor. This motor is the invention of Hr. Leo Schüler, an electrical engineer of Frankfort, Germany, and is made by the Wagner Electric Company, of St. Louis. In construction it is a combination of the repulsion and induction forms of single-phase motors. Mechanically, the motor consists of an ordinary induction motor frame. It has an ordinary induction motor stator core, built up of laminated sheet steel. The stator winding consists of form-wound coils, distributed in slots around the inner periphery of the stator core. The motor is built up of laminated steel in the same way as the stator, and carries a progressive wave winding similar to the usual direct-current armature; on one side is provided a commutator and on the other side three collector rings connected into the winding in polyphase relation. In operation the first effort of rotation is secured with connections corresponding to the well-known repulsion motor. After the armature has attained about one-quarter speed the polyphase resistance, connected to the armature through the slip rings, is thrown in and gradually short-circuited as the armature runs up to full speed. The brushes bearing on the commutator in the usual elevator equipment are not completely short-circuited, but have a fixed resistance interposed between them; at no time are the brushes removed from the commutator. An outfit which has been in service for six months has operated with extremely satisfactory results. The sparking is practically *nil*, and the life of the commutator is predicted to be equal to that of the best direct-current elevator motors.

In the discussion Mr. Alex. Dow said that up to the present the companies regularly installing elevator work, when asked for an alternating-current motor, evaded the subject. In reply to a question, Mr Cole stated that it is the intention of his company to develop the type of motor described in the paper for hoist and traveling crane service, and that they intended to cooperate with elevator manufacturers to whom they will supply the motors and speed controllers. Mr. Renshaw considered that the motor described corresponded closely to the direct-current, compound-wound motor. The motor is in the same class for such work as cranes and hoists as the induction motor. For elevator service the compound motor is what is desired, but for cranes and hoists and work of that class a series motor is necessary to get the full advantage obtained from direct-current service. In reply to a question as to why 25-cycle motors are wound for 220 volts and 60-cycle for 110 to 125 volts, Mr. Renshaw stated that a high frequency required a larger number of commutator bars and that a high voltage would make the bars too narrow for mechanical running.

Long-Distance, High-Tension Transmission in California.

The paper by Mr. John A. Britton gave a résumé of what has been accomplished in the past ten years in the development of the electric transmission systems now under the control of the California Gas & Electric Corporation. The paper describes both the old and the new arrangements employed in the power stations and in the transmission lines, thus indicating the arrangements which have best withstood the test of service.

The Organization of Working Forces in Large Power Houses.

The author, Mr. W. P. Hancock, gives a diagram showing the organization of the generating system of the Boston Edison Company, which has in service a total of 172 men. The specific duties and responsibilities of each man or group of men are outlined. It is stated to be the policy of the company to show every employe that his position has a value both to the company and to himself; to show that the value of the position to the employe was what the employe himself could make it, aided by the counsel and instruction of the superior who had his services in immediate charge; and by paying a uniform rate of wage for a uniform quality and quantity of labor in every line, the company has adopted a treatment of its men conducive to contentment and was reasonable in assuming and expecting good service.

Mr. W. B. Jackson, of Madison, Wis., in discussing this paper, spoke of the desirability of keeping a plant in a clean condition, not only owing to the effect in inspiring confidence in customers with respect to reliability, but also for the good effect on the morale of the employes. He said that when one goes into a dirty plant he sees slovenly employes, while when he enters a clean plant he sees bright, attractive employes who appear pleased with their work. In reply to a question Mr. Hancock stated that his plant paid firemen $16 a week if they were good men, and if not they did not want them. Operators are taken in at as low as $10 a week and moved up as fast as practicable. He said he did not have a union man on his pay-roll for the reason that a scale of wages higher than that of a union was paid. He believed his men were far above the average of the union men of to-day. For example, firemen get $16, whereas the union scale in Boston is $14 a week, and when delegates of the union call and are told that a higher scale of wages is being paid, they have nothing to say. The men are kept from becoming union men through being paid more wages than they could get as union men. Mr. A. C. Dunham, of Hartford, stated that during the last three years his men have been given an annual dividend of 6 per cent, and that there had not been any opening for a union man since this practice was commenced.

Operating Features of Vertical Curtis Steam Turbines.

A paper on this subject was presented by Mr. August H. Kruesi, who cited the experience already had with the Curtis turbines, and gave numerous suggestions as to the installation and operation of these machines. It is comparatively easy to secure such freedom from vibration in all sizes of turbines that a coin will stand on edge at the top of the machine indefinitely, and after having been brought to this condition when first started, the machine will require little further attention on this account. The shaft should run true and the bearing shield should be concentric so that the maximum excentricity will not exceed from .002 in. to .004 in. in turbines from 500 to 5,000 kw. capacity, respectively. To eliminate the packing at the lower end of the shaft the step bearing is generally lubricated with water, the shaft being fitted with a bronze sleeve running in a babbitt-lined guide bearing. By the use of a baffler it is possible to operate 500-kw. and 5,000-kw. turbines from the same pumps and piping system economically and satisfactorily under every condition. The step bearing has shown remarkable sturdiness when subjected to cessation of forced lubrication. To illustrate this a test has been made in which a 500-kw. turbine was run up to speed, lubricant and steam turned off simultaneously, the turbine brought to rest due to the friction of the step, and immediately re-started, six times in succession, without difficulty of any kind. After raising the lower bearing plate by means of the adjusting screw to compensate for the wear of the plates, they were just as good for further service as at the beginning, although naturally somewhat grooved. The type of valve mechanism which will ultimately prevail as the simplest and most satisfactory can be determined only by practical experience. With a view to ascertaining the best type, various forms of mechanically and hydraulically operated valves are under test in service conditions. The mechanically operated valves derive their motion from the turbine shaft under a fixed period, depending upon the turbine speed and, therefore, have no tendency to accumulate changes in speed or cause hunting. The governor controls the number of valves to be opened or closed by a modified Corliss release mechanism. The hydraulically operated valves are positively opened and closed by a cam shaft under the control of a hydraulic cylinder, the piston of which connects with a follow-up attachment which makes it absolutely non-hunting. After discussing turbine-driven auxiliaries, condensers and steam consumption, the author concludes that the saving in first cost alone

between the turbine and engine-driven units is equivalent in fixed charges to a reduction of the water rate. The saving of the condensed steam by the turbine, where feed water must be bought at ordinary city rates, is also considerable, as is that effected by the less attendance necessary for the turbine. All of these considerations, however, are of minor importance as compared with the reduction in steam consumption indicated by various tests, because there is hardly any part of the equipment of a power station whose capital and operating costs cannot also be reduced as a direct result, such as boilers, stack, coal-handling apparatus, condensers, pumps, etc.; or, in other words, a reduction of 10 per cent in the water rate of the turbine means a station of 10 per cent greater capacity and output for the same investment, fixed charges and operating expense.

In reply to a question, Mr. A. H. Kruesi stated that no turbines operating with exhaust steam are as yet in operation, but some are nearly completed and quite a number have been ordered. Two sets have been ordered by the Philadelphia Rapid Transit Company.

Some Investigations of Induction Losses.

Mr. E. P. Dillon's paper deals with the detrimental effect of the wattless component of the current in a supply system. After having mentioned the causes for the wattless current, the author determines the losses in a line having certain assumed constants and expresses the results in electromotive force, energy and dollars. It is suggested that synchronous motors may be caused to introduce leading wattless currents by over-excitation of their fields, and thus may be employed to neutralize the wattless currents in the system. The kilovolt-ampere rating of the synchronous motor for such work is calculated for assumed conditions. It is stated that the most prolific source of low power factor is due to the use of induction motors which are operated at less than one-half of the rated load. A remedy would be found in embodying in contracts a clause specifying that the motors installed shall have rated capacities within a certain percentage of their individual loads.

The Choice of an Insulated Cable.

Mr. W. S. Clark is the author of this paper. The size of the conductor is determined by well-known thermal and economical laws in most cable installations. It is important, however, that for underground construction there be not used cables so small as to be mechanically weak. A diagram is given showing the variation in cost per 1,000 circular mils of copper contained in the cable for different sizes of cables and different working e.m.f.'s, from which it is seen that, with a 15,000-volt cable, changing the size from No. 8 to No. 6 increases the cost less than 4 per cent, while the conductivity is increased 58 per cent. As to whether single or multiple-conductor cable should be used, it may be stated that for station wiring single conductors in separate ducts might safely be taken as the best modern practice, while for outside lines the determining factor will be the nature of the service. For low tension mains on the three-wire system the three-conductor cable is slightly cheaper than three single-conductor cable, but not nearly as convenient for making taps to customers. For low-tension feeders, which usually exced 25,000 circular mils in size, the concentric type of cable should be used for maximum duct economy. Smaller cables may be run as a flat twin conductor. For three-phase work, three-conductor cables, and for two-phase, four-conductor cables are required, on both economic and engineering grounds. The paper advocated a type of insulation now used by the General Electric Company which was claimed to possess all of the good qualties of paper, to be more flexible, to have a considerably higher dielectric strength, and which does not absorb moisture and can be used in interior work. These advantages are stated to be found in varnish and cambric, which will not deteriorate under temperatures destructive to rubber insulation.

Apparatus and Methods—Insulation Testing.

The writer, Mr. C. F. Skinner, discussed briefly the elements that should be considered in the design, selection and use of apparatus for making electric tests. In high-tension transmssion work the testing voltage is usually from one and one-half to two times the normal rated e.m.f. of the apparatus. Tests of 100,000 to 150,000 volts will cover any commercial work, and 250,000 volts should be sufficient for any investigation in connection with commercial work. Testing apparatus capable of giving half a million volts is merely a scientific curiosity at the present time. The author gives a table showing the relative ratings of testing transformers, from which it is noted that for maximum testing e.m.f's above 30,000 volts the current rating should be one ampere and for lower e.mf's the rating should be two amperes. Due to the charging current of a piece of apparatus considered as a condenser, for a given condition of test a larger testing transformer will be required for high than for low frequencies. It is stated that each of the 5,000-h.p. generators for the Niagara Falls Power Company has a capacity of about 0.3 microfarad, and the capacity of each of the 5,000-kw. generators of the Interborough Rapid Transit Company is 0.6 microfarad. The size of the transformer for supplying the charging power for the former machine at 25 cycles and 6,000 volts is 1.7 kilowatts, while that for the latter machine at the same frequency and 25,000 volts is 50 kilowatts. The three principal methods of varying the testing voltage when making dielectric tests are: (*a*), by carrying the field strength of the generator; (*b*), by means of a resistance in series with either the primary or the secondary circuit of the testing transformer, or (*c*), by bringing out loops from the high-tension side of the testing transformer, with further combinations of the low-tension windings. The last method is by far the most satisfactory. There are given numerous diagrams showing such arrangements suitable for both low and high-voltage machines. The author states that in the measurement of the testing voltage the method involving the use of the spark-gap has many disadvantages and few advantages. The voltage measurements are very unreliable unless an elaborate set of shields is used, and there is much controversy as to the actual distances which represent given voltages. A more satisfactory method is by the use of a voltmeter transformer. This method is very expensive with very high voltages for the reason that the voltmeter transformer is very difficult to wind and insulate for such small outputs. It is good practice in manufacturing work to test each part as it is finished, as well as the completed apparatus, in order that any defective workmanship or material may be discovered before the parts are finally assembled, and it is customary to grade the test voltages from higher to lower values as the apparatus nears completion. The paper is illustrated with a number of views of Westinghouse testing and regulating transformer outfits and by diagrams of connections.

Mercury Arc Rectifiers.

After discussing the various devices now available for charging storage batteries by power obtained from alternating-current sources, Mr. P. D. Wagoner described in detail the General Electric type of mercury arc rectifier. It is stated than the only part of the rectifier set that can require renewal is the tube and that the life of the tube under normal operating conditions is at least 400 hours, while some tubes have operated for 3,000 hours It is shown by means of calculation based on service conditions that the saving in cost of energy due to the higher efficiency of the rectifier set over a motor-generator set is sufficient to pay for a new tube in about 124 hours. The mercury arc rectifier makes possible the operation of the magnetite lamp from the well-known constant-current transformer on alternating current circuits. Such a system of street lighting has been operated by a central station for some time with remarkably satisfactory results.

The Tantalum Incandescent Lamp.

Dr. Louis Bell's paper gave an account of the test of some 25-hefner, 110-volt tantalum lamps used by the author and Prof. W. L. Puffer, two of the lamps being tested for decay. The light of the tantalum lamp is, as might be expected from its high efficiency, rather whiter than that of an ordinary incandescent, being as white as the Nernst lamp or the acetylene flame. Its distribution of light is in the present form of filament rather less uniform than that of the common incandescent lamp, being relatively more powerful in a horizontal zone and less powerful for points near the axis. The ratio of mean sperical to mean horizontal candle-power as found in Prof. Kennelly's investigation of the frosted lamps, proved to be .73 and Dr. Bell's figure from the clear lamps was substantially the same. The distribution, however, could very easily be improved, so that the spherical reduction factor would not differ materially from the usual figures and the light at the top could

be correspondingly increased. Since the tantalum filament has a low initial resistance (between 55 and 60 ohms) it jumps into incandescence with startling rapidity as compared with a carbon filament, but because of its positive temperature coefficient it seems to be decidedly less sensitive to changes of voltage in its working condition. This is a useful property in certain respects. The fact, however, that the initial resistance of the tantalum is so low and its thermal inertia so small owing to its small mass and low specific heat, means rather violent heating up, which is probably the cause of some doubts which have been expressed as to the endurance of these lamps upon alternating circuits. It is not difficult to imagine pretty severe strains upon the filament if it had time to cool down much between impulses. If such cooling could take place, for instance, on an ordinary alternating circuit, the results might be serious.

Some stroboscopic tests were, therefore, made at the last moment to determine whether at, say, 25 cycles, there was a specially violent fluctuation of light from the tantalum lamp; in other words, to find out whether on a 25-cycle current the filament had time to cool down materially. The result showed that the light fluctuation at this frequency was somewhat but not much more pronounced than in a carbon filament. The tantalum lamp behaved in fact about like a 16-c.p. carbon filament lamp. Even a 75-c.p. carbon filament lamp, however, shows perceptible variation under this test. At 60 cycles the fluctuation, while still perceptible, was trivial both in the tantalum and carbon lamps. It hardly seems probable that at 60 cycles the life of the tantalum would be enough impaired to cause serious trouble, but the writer now has some lamps on alternating-current tests and proposes to pursue the inquiry.

The tantalum filament seems to stretch and sag at first as if undergoing annealing and losing the set produced by drawing. Then it shows local bright spots which grow lumpy as if the material tended to flow a little from the heat, and with the increasing lumpiness the filament draws up tight. At this stage it is rather fragile and would probably break easily from vibration or shock. It seems likely that the final break comes just where one of the lumps has reduced the cross-section of the wire beside it. The break in the lamp during test, already referred to, showed considerable attenuation of the loose end.

The lamps tested showed the following characteristics:

Lamp.	Watts.	C.P.	Watts per candle.
Clear Globes....	41.58	21.42	1.94
	38.61	20.90	1.84
	41.58	24.93	1.66
	41.58	21.55	1.93
	41.91	21.81	1.92
	41.91	22.59	1.85
Frosted Globes..	40.36	19.79	2.03
	40.34	18.54	2.15
	40.04	18.74	2.13
	40.48	19.27	2.09

The mean result from the clear globes was 22.2 candle-power at 1.85 watts per candle; that from the frosted globes 19.98 candle-power at 2.1 watts per candle.

It is interesting to note that the clear lamp gives just about 1 candle-power per inch of filament, which implies an intrinsic brilliancy of somewhere about 500 candle-power per sq. in. of filament—a figure much higher than in the ordinary incandescent.

As illuminants the lamps are certainly very excellent, but their introduction raises some most interesting questions for the central station operator. Putting aside all the petty questions that will be raised about the new lamp for commercial reasons, the broad fact remains that we are here dealing with a bona fide 2-watt lamp having a life fairly comparable with the carbon filament lamps now customarily in use. Moreover, it is a competitor of these, socket by socket, and not as a substitute with particular requirements, as in the case of the Nernst lamp or the very small arcs. There is some doubt as to the life of the tantalum lamp when exposed to unusual vibration, which may perhaps bar it in some special locations, but for the everyday work of the central station there is good reason to believe it generally applicable.

Its price can hardly be said to be fixed in this country, but abroad in Berlin it is about one dollar (4 marks), which will give at least a fair line on its commercial results. On this basis and with power at 10 cents per kw. hour, one finds taking the new lamp on its 600-hour rating that the cost of its 12,000 candle-hours, including the lamp, amounts to $3.40. The same number of candle-hours from a lamp giving a mean efficiency of 1.25 watts per candle would cost $3.90, exclusive of lamps; that is, the consumer could afford to pay $1.00 for the new lamp better than to take the old ones free. With power as low as 5 cents per kw.-hour, the user of tantalum lamps could afford to pay only 75 cents per lamp as against getting carbon lamps free. This means that a sliding scale of discounts for lamps according to quality could be made to catch the consumer at all prices ordinarily charged for current by central stations.

Does this mean that the carbon lamp will shortly be down and out? Probably not, for there is no spur like competition to start up improvements, and there are some signs that carbon lamps may be improved enough in efficiency to make things interesting, at least with current at the prices charged to very large consumers. This, however, remains to be seen, and the thing which the central station man has to meet is the immediate probability of consumers putting upon their circuits lamps taking less than two-thirds the watts per candle-power of the best lamps now in use, and thereby cutting down their meter bills enormously. Now, broadly, what shall be the attitude of the central station man toward this income-scalping innovation? There are some managers who may be inclined to put up a fight to discourage the user, either by raising pettifogging objections or by trying to discriminate against 2-watt lamps by readjusting discounts in various ingenious ways. Dr. Bell is very strongly of the opinion that such a policy is wrong and will certainly lead to ultimate disaster in the form of municipal restrictions or regulation of rates by law. In the long run, opposition to improvements does not pay. If, on the other hand, the central station man hangs quietly on and gives the consumer the glad hand, the change will work to his ultimate benefit. In the first place, the tantalum lamps now made are of 22 candle-power instead of 16, and the filament will hardly bear much reduction in cross-section. The tendency, therefore, will be to use these slightly more powerful lamps taking, say, 42 watts instead of a trifle over 50 watts in the 16-c.p. carbon lamps. The actual loss in energy sold is likely, therefore, to be for the present quite a little less than the difference of efficiency would indicate.

Besides this, the attraction of cheaper light will certainly bring into line new consumers, so that the net result will probably be an actual increase in sales of current, quite a little of it being among the smaller consumers who pay the higher rates. Such a change means upon the whole more lights per unit of capacity in transformers or feeders, and hence a slightly better utilization of material and improved load. In the case of stations with underground service, the change to 2-watt lamps ought to bring with it increased earnings per unit of cable capacity. The fact is that improvements in the efficiency of utilization of electric energy help the business, and it is both fruitless and inadvisable to oppose them from any short-sighted notion of small temporary savings.

As to the inevitable competition between present lamps and the newcomer, in the first place, the merits of the final issue remain to be determined, and in the second place competition in lamps is, on the whole, a good thing for the user of them, however it turns out. So far as the central station is concerned, it is a case of dog eat dog.

The really important thing is that from now on the station manager will have to deal directly with the 2-watt lamp proposition, for there is no disguising the fact that it is here, and in a form which is quite unexpected. The appearance of tantalum lamps in quantity may be a little delayed in this country, but delay will improve them as in the case of every new product, and will serve to assure a better understanding of their truly remarkable properties and of their possible limitations. The unexpected has certainly happened, for most engineers had long ago abandoned the idea of a lamp with a metallic filament. Only the discovery of a metal virtually new, and possessed of most sensational qualities, could have brought about the present striking result.

In the discussion of Dr. Bell's paper, Mr. Arthur Williams, of New York, stated that his company had a number of these lamps on test and they promised a very marked improvement in the economy of incandescent lamps in the future. He believed, however, that if the price of the lamp remained at its present figure, $1 in Germany and perhaps $1.50 or $2 here, it would not be a serious competitor with the incandescent lamp; and as there probably have not been more than 100 of these lamps in this country and they have not been here long enough to be subjected to any commercial test, he

did not think it would be practicable to discuss the lamp in any commercial sense. The high lamp cost will minimize it as a factor in competition with the carbon filament lamp.

Mr. John F. Gilchrist, of Chicago, considered that the new lamp raised the question of selling electricity for illuminating purposes on the lamp-hour instead of kw.-hour basis. The new lamp would cut down the income of the station, and while it is unwise to attack anything which has merit, the station manager may want to hold it back until he can build up his business to meet it and not impair the income. He suggested that the association and electric light men should guide legislation along the lines of charging on the flat hour basis so that a new lamp of the tantalum type could be used by central station men with advantage to themselves. Mr. A. C. Dunham, of Hartford, Conn., said that he had experimented with the tantalum lamp and found that the figures given in Dr. Bell's paper are practically correct. They will burn a long time after a filament breaks, the filament mending itself. He referred to the system brought into vogue by the osmium lamp, where central stations are charged 20 cents per lamp per month rental, the manufacturers supplying repaired or new lamps for lamps burned out. Mr. Dudley Farrand said that his station had two of the tantalum lamps. One showed a consumption of 1.99 watts, but lasted only 20 odd hours. The second lamp is still burning and has shown a consumption of 1.68 watts. Mr. Farrand did not think that the tantalum lamp would work against the interest of the central station at all. Every time the efficiency of a lamp is doubled the capacity of the plant is doubled, and while the higher efficiency may tend to increase the distribution expense, the net result will all be in favor of the high efficiency lamp. He expressed himself as highly in favor of the tantalum lamp and only wished he could get them in sufficient quantities to supply his business to-day. He did not consider it would upset the commercial status as the business would increase with the introduction of the lamp faster than the lamps could be put into use. Mr. W. H. Gardiner, of Boston, thought that the new lamp would enable the candle-power of lamps to be increased to compare with that of gas or to about 25 candle-power as a unit. He welcomed the opportunity to increase the candle-power rating and pointed out that a similar increase had worked well for gas companies upon the general introduction of the mantle gas burner.

The Nernst Lamp—Its Present Performance and Commercial Status.

Mr. E. R. Roberts' paper presented the results of a series of life and photometric tests of Nernst lamps recently made by the manufacturers. The method of making the tests and the photometer used were fully described. During the life tests the lamps were operated under what is considered good maintenance conditions, the globes and holders being cleaned every 200 hours. The decrease in mean hemispherical candle-power amounted in 1,000 hours to 22 per cent, the greater part of which took place in the first 300 hours. The initial consumption per mean hemispherical candle-power was 3.31 watts and per mean hemispherical candle-power was 1.95 watts. At the end of 1,000 hours the values had increased to 3.78 and 2.27, respectively. It is stated that, while the Nernst lamp properly belongs to the class of incandescent lamps, from the maintenance standpoint it is more akin to the arc. From the reports of the 7,000 glower units in service in the Pittsburg district it is learned that the total maintenance cost per glower per month is 9.56 cents, and it is estimated that the cost for maintenance per kw.-hour of energy used is 5.2 mills. This figure agrees closely with the average cost reported by a number of companies who use the lamp on a large scale.

Replying to a question concerning direct-current lamps, Mr. Roberts stated that arrangements have been made to distribute a number of these lamps to central stations for commercial tests, and the result of these tests will be awaited before the lamp is placed regularly on the market. Mr. Arthur Williams said that his experience in New York City showed that the Nernst lamp does not materially interfere with the field of incandescent or arc lighting, but fills a gap between the two. The light is of high quality and wherever used gives entire satisfaction. The three and six-glower lamps are more advantageous commercially than the single-glower lamp. The life is fairly satisfactory and the cost of renewal slightly over one cent per kw. hour, and probably would be less than one cent were the lamps used to a larger extent. The income is substantially $11 annually per 88-watt glower, which is about twice the average income of an incandescent 16-c.p. lamp. Through the Nernst lamp the New York Edison Company has secured the return of a large amount of business which had gone to intensified gas burners. Mr. A. C. Dunham, of Hartford, Cann., said that he was using 3,500 Nernst lamps and the lamp has filled the place so well that they do not see how they could possibly get along without it. As a displacer of high candle-power gas lights it is remarkable. The life of the glower is now from 800 to 840 hours, though one lamp has now been running over 1,700 hours. He did not think it advisable to get the full life out of the glower, as this would almost surely result in burning out the heater, which is a very expensive affair, the list price being 75 cents. Single glower lamps are not allowed to burn over 450 hours. In the case of a rated 50 c.p. Nernst lamp it would burn for the first 50 hours 71 candle-power then drop to 62 and stay there for 450 hours, after which it begins to drop more rapidly. He considered that if the price of glowers was greatly reduced sales would increase very materially. In reply to a question, Mr. E. R. Roberts stated that the Nernst lamp was used for street lighting in Unionville, Conn.; Sewickley, Pa.; Burlingame, Kan.; Burwin, Ill.; Goldfield, Nev.; Golden, Col.; Deming, N. Y., and Coalinga, Cal.

Sign and Decorative Lighting.

The author, Mr. Larue Vredenburg, dealt with the subject from its purely commercial side. One thing that has acted as a decided handicap to the introduction of electric signs in many cities and towns is the restriction placed by ordinance on the size and position of signs. A properly directed effort on the part of the lighting companies will undoubtedly tend to the correction of this condition, as the benefit accruing to any town from the added illumination of its streets by means of signs is so self-evident that but little argument is necessary. The method pursued by one of the large companies last year was a persistent and systematic advertising campaign by means of letters, return postal cards and enclosed stamped envelopes, sent to a selected mailing list including all retail merchants in all lines of business whose stores were sufficiently pretentious to possess plate-glass windows. This campaign last year resulted in more than doubling the number of sign customers in a city where an ordinance restricts the projection of signs to two feet from the sidewalk line. Consequently, most of the signs installed are placed either vertical or flat against the face of the building. A field that shows quite a promising crop for lighting companies is the illumination of bill-boards. These are generally controlled by advertising concerns, who are beginning to appreciate the increased value of their space when properly illuminated.

Another type of sign which appeals strongly to the general advertiser is the so-called "talking sign." This sign, although quite expensive to install and adapted to use in only the larger cities, is of such versatility and attractiveness, enabling the user to present such varied and extended arguments, that it should prove a profitable investment.

Free Signs and Flat Rates.

Mr. C. W. Lee, the author of this paper, considered only that phase of the subject which relates to the possibilities presented in the use of the electric sign as a means of obtaining long-hour customers. The flat rate has a particularly good effect on sign lighting, as it insures use of the sign six or even seven nights a week, while those operated on a meter basis are used only the nights when the store is open, which is the time when there already exists a large demand for the current. With a view to further increasing the sign business the company with which the author is connected has recently placed in operation a plan whereby the greater portion of its sign lighting will be entirely removed from its peak during the months when the peak must be considered. Free signs on a flat rate for certain stipulated hours each night are the nucleus of this plant. The time of switching on is placed about half an hour after the peak load. The turning on and off of signs is controlled by patrolmen, who not only attend to these duties but inspect all signs as well as solicit new business. It is expected that as soon as this plan is under full headway the increased business will necessitate the running of

special sign circuits from the station. In this event the expense of patrolmen would be eliminated. Isolated signs at some distance from the main streets are controlled by time-switches. Before the adoption of this flat-rate schedule it was argued that no customer would be willing to contract for a sign that could not be turned on during the first half-hour of darkness, but experience has proven that this question is waived in many instances, the specific rate overshadowing this point.

Both of the foregoing papers, together with a paper on "Advertising Methods," by Mr. Percy Ingalls, were discussed together. The discussion brought out the fact that advertising in its various forms pays. The methods pursued in various large cities, especially Denver, were expatiated on and it was shown that even in comparatively small towns where competition with cheap gas was keen, excellent results were obtained by intelligent and systematic advertising. For increasing business nothing else was comparable to it.

Report of the Committee on Progress.

After giving numerous statistics of the industry showing developments abroad and in America, the report by Mr. T. C. Martin takes up the subject of illuminants. Descriptions are given of impregnated carbon arc lamps, mercury vapor arc lamps, tantalum filament incandescent lamps, the osmium and the cadmium lamps. In discussing the unexploited fields for the use of electric power, the author drew attention to the advantages to the central station of acquiring a refrigerator power load, and stated that wherever power can be furnished at a rate less than 5 cents per kw.-hour automatic refrigeration by means of apparatus now available effects a large saving over the cost of ice, even if the manifest advantages of cleanliness and convenience of operation be not considered.

Report on Present Methods of Protection from Lightning and Other Static Disturbances.

This report, by Mr. Alex. Dow, forms a brief review of present practice and does not attempt to give any new theories or to describe any untried devices. It is the function of the lightning arresters to protect the apparatus used in transmission lines from lightning, from high-frequency waves set up by sudden changes of load or by resonance, and from static charges. The essential features of a protective apparatus are as follows: (1) They should discharge at a potential slightly higher than that of the system. (2) The ordinary working of the system should not be affected by the discharge. (3) The electric energy of the static disturbance should be dissipated as rapidly as possible. (4) The static waves should be prevented from developing high-potential differences in generators, transformers and other apparatus. Among the various devices used for protection the author describes the General Electric arrester for 2,000 volts, the Westinghouse arrester for 2,000 volts, the Westinghouse low-equivalent arrester, the horn arrester and the water-jet arrester for alternating-current systems, and describes the Thomson magnetic blow-out arrester, the Westinghouse direct-current arrester, the Garton arrester and the Westinghouse tank arrester for direct-current systems. He concludes that there is still much to be done before it can be claimed that the lines are perfectly protected. The engineers of the manufacturing companies have developed apparatus that operates successfully under ordinary conditions, but each transmission lines presents a separate problem which can be solved only empirically.

In the discussion of the paper Mr. Dow said, referring to the water jet arrester, that this was merely a leg of high resistance and of no inductance, and that it consumes energy continuously. The water jet might be used to good purpose in many high-tension transmission lines as a special protection during thunder storms in much the same way as in certain railway plants the tank arrester is switched on during thunder storms. In conjunction with choke coils it would furnish a thoroughly reliable means of protection, though its use involves a loss of energy from 3 to 10 kilowatts, depending upon the voltage. From information received since the report was prepared, the use of a single ground wire, instead of two, was recommended. No reliable information could be obtained concerning the horn arrester, but it seemed that the tail piece is dispensed with entirely in many European plants. Mr. Dow advised the appointment by the association of a reporter to gather information on the subject of lightning protection and to report the same at meetings. In reply to a question, Mr. Dow said that flashing across storage battery terminals to ground has happened, the discharge being across the surface of the tanks. Mr. R. F. Hayward stated that in Utah there are about 300 miles of 40,000-volt and 200 miles of 28,000-volt lines running in parallel, and scarcely any storm passed through the territory covered without striking something, either directly or inductively. He has come to the conclusion that the lightning protection should be spread all over the line in the form of lightning conductors. It is found that when a storm occurs it will generally strike the lines and split a number of poles, shattering all the insulators on one pole and puncturing a number of insulators on other poles. The effect is seldom found far from the point where the stroke comes, and if the stroke is near the power house some apparatus is likely to be lost or terminals burned out. A number of transformers of the old air blast type have been lost, but none of those with new windings which have replaced the old type, although in a recent storm some of the terminals were burned off. The arc will cross from terminal to terminal, jumping distances of 5 or 6 inches, and while this shuts down the plant for a moment, no other damage is done. Recent experience has shown that modern insulation, whether of the air-blast or oil type, is becoming very good and very high. Mr. Hayward considered that the ground wire should be placed on the line; if there is no ground wire on the line, one of the two circuits is grounded at each end of the line when a thunder storm comes along. If a ground wire is above the other lines, it should be as far above as possible, for then the stroke will discharge to this wire and take the ground by a number of different paths, whereas if the ground is at the neutral point of the main circuit it is almost certain to cause an arc that will give a short circuit, and these sudden short circuits are the cause of setting up low-frequency waves which go into the power house, pass through the choke coil and are liable to break down the apparatus.

Mr. E. P. Dillon stated that the Colorado Springs lines were partcularly menaced by lightning. At present lightning arresters are liberally distributed at the various plants and sub-stations, but there are none on the line, since it is felt that the risk of having lightning arresters on the line was an offset to their advantage. He thought that a well-constructed ground wire would obviate some of the difficulties which have been met with. At three different times in the past two years the lines have burned out directly in the middle of a span, and not at the poles. Last December during a heavy wind there were some exceedingly severe static discharges from the lightning arresters which appeared to be heavy enough to destroy apparatus, though taken care of by the arresters. Lightning and static disturbances are practically unknown at high altitudes, while valley lines suffer severely. This he considers to be due to the fact that the clouds come down so low that there is not much of a chance for a great difference of potential between them and the earth. On the Pike's Peak hydro-electric plant there are installed a combination of spark gap and high-resistance arresters and a water tank, which combination has carried the plant through several severe storms. Mr. Dillon did not approve of barbed ground wire owing to the uneven quality of the wire, which caused it to break and give rise to more serious trouble than from lightning. A well-made steel wire of good tensile strength would give very good protection and help out the regular arrester. At the main generating station high-resistance arresters were installed in combination with the spark gap; these did not completely take care of the trouble and about two years ago they were put in a series parallel arrangement giving the discharge a straight path to ground or a split through the arrester, and since then there have been no discharges at the switchboard. Mr. George R. Stetson, of New Bedford, Mass., said that last December in two weeks more motors were destroyed than in all the previous fourteen years in the operation of the plant, due to a static manifestation. Some of the motors were served by the underground system and some by the overhead system, and finally the trouble went beyond the motors to the station generators. The trouble to some extent has been remedied by putting up lightning arresters and kicking coils. Mr. Orville A. Honnold, of Salt Lake City, said that in experiments with lightning arresters several types had not given good results, and he believed that the

Pike's Peak plan would solve the problem. Mr. H. T. Hartman criticised the suggestion to locate the ground wire at the center of the three-phase diagram for the reason that this would virtually reduce resistance between the wires. Mr. W. B. Jackson, of Madison, Wis., stated that in northern Italy the water jet arrester has recently been put in use, and since then the former trouble from static effects has ceased. Mr. Dow stated that the water jets on the Italian lines are very satisfactory, and he thought that this was the most comprehensively reliable arrangement available for protection against either lightning or static discharges, when installed in connection with choke coils. The objection to the jets is that they take energy, but they may be held as emergency devices and thrown into service only upon the appearance of symptoms of static discharge. As to the position of a ground wire with reference to a three-phase line, this point would be at earth potential if, as is usually the case with Y-connected step-up transformers, the central station point of the wire is connected to the earth. He considered that the experience of Mr. Stetson was due to quick breaking of short circuits, which put a bad stress on a line. As to lines charged statically, sand storms produce the most aggravated cases. In conclusion he stated that it cannot be made too strong that the provision of low-resistance, non-inductive paths to ground is the perfect type of protection.

Report on Purchased Electric Power in Factories.

Mr. E. W. Lloyd's report contains a compilation of valuable data connected with the electric power loads on the central stations belonging to the association. In discussing the question as to whether a factory should run from central station service or whether it should generate its own power, the author stated that the decision is not always governed by the rate per kilowatt hour which the central station company proposes to charge for the power. To anyone who has had experience with installations of motors driving machinery where one large motor was used, it is known that no economy can be obtained over engine drive with profitable rates for central station service. It may be possible with the use of a few motors in a large plant running 15 to 24 hours a day with a low rate per kilowatt-hour, that central station power can compete with engine drive; but the average plant does not run more than ten hours a day, and, therefore, the rates of a central station company doing a profitable business cannot compete successfully with these conditions. It is, therefore, necessary to consider other sides of the factory power subject than merely the question of price per kilowatt-hour. While it is true that the installation of individual motors increases the connected horse-power load in a given factory over and above what it would be should group-drive installation be made, it is also true that the energy consumption is considerably less on the individual motor installation. There are engineers throughout the country who advocate individual motor installation, but the subject has not received the proper consideration from all central station companies, and the sooner it is brought forcefully to their attention that this type of installation will do more to increase their power load than any other one thing, the more universal the practice will become. The selling by some companies of electric power at very low rates even to the extent of losing money on this power is not necessary with proper motor installations. Extremely low prices for electric power in some localities are detrimental to the station business in others, and they are not necessary if the proper attention is given to the engineering features in obtaining power business.

In the discussion Mr. A. C. Dunham, of Hartford, Conn., said that his plant is now operating a little over 5000 horse-power in motors. He referred to one case where a manufacturing company opened its books showing the cost of its steam power and agreed to pay 20 per cent more for electric power, which offer was accepted. He has found that the output for the motor service is about 40 per cent of the rating of the motors connected. Mr. H. J. Gille thought that a good source of revenue could be derived by supplying power in the summer time where there are isolated plants; as one of the principal objects of such plants is to supply steam for heat during the winter, they could with profit be shut down in the summer time and current for lighting taken from the street mains. Mr. W. C. L. Eglin called attention to the fact that averages with relation to motor installations might not mean much for the reason that one or two large motors in a machine shop, for example, might give a large average, whereas many small motors might be in use. Mr. Gilchrist showed the desirability of determining the actual cost of steam power to a prospective customer of electric power, in order that figures could be derived to show the superior economy of electric power. He related an instance where, after such a study of a plant, an owner who had used some steam for drying lumber was induced to put in a hot air kiln for this purpose to use up refuse; it was then found that the cost for electric power per month involved a considerable saving to the factory. As to averages, taking the case of machine shops, which run from 12 per cent to 70 odd per cent of the connected load, to strike an average bebetween the two of, say, 40 per cent, would give no criterion. Taking all the installations of, say, four motors or more, it would be found that the highest average is 62 and the lowest average is 40 per cent.

Electric Heating.

Mr. J. I. Ayer presented the report of the committee on "Progress in Electric Heating." In order for electricity to compete with gas at $1.00 per thousand, current for cooking must be 3 cents per kilowatt-hour. It required about 300 watts per day per person for electric cooking, and the wiring should have a capacity of at least 35 and not more than 45 amperes for a family of four to six persons. Progress was chiefly made in the use of electricity in laundries. The use of electricity for heating dwellings and water was not advisable, considering that this could be done more cheaply otherwise.

District Heating.

The report of the committee on district heating was submitted by Mr. W. H. Blood. From the report it appears that 84 per cent of the companies approached find their investment in the heating business a good thing, which 16 per cent. were not at all satisfied with the business. It was stated that all direct-current plants are located near enough to the center of distribution to warrant district heating. For a central station which is a mile or more away from the center of the city, however, district heating is generally out of the question. An element of extreme importance is the relation of the cost of steam coal to that of domestic coal. In cities where steam coal costs from $1.00 to $2.00 per ton, and where domestic coal costs from $4.00 to $9.00, the company has much in its favor and should be able to make rates that are at once attractive to the public and profitable to itself. It seems safe to estimate for ordinary conditions where exhaust steam is used about .2 pound of water per hour per square foot of radiating surface. So long as the demand does not exceed the supply of exhaust steam, but follows it closely, and the rates are kept up, the plant is in a fair way to make money; but any plant that undertakes to sell live steam on an exhaust-steam basis is doomed to failure.

The association issued to its active members at Denver three highly important documents. The first of these was the report on "Municipal Ownership," by Mr. Arthur Williams. A large number of plants are considered in it in detail, and Mr. Williams' results should be found extremely serviceable by persecuted central station men all over the country. The book is a volume of over 200 pages, carefully digested and indexed and bound in cloth cover. The other two productions given out were the "Question Box" and the "Wrinkles" pamphlet. The former, edited by Mr. Homer E. Niesz, is a volume of 594 pages, replete with information, containing 3057 answers to 545 inquiries relating to all branches of the light and power art. "Wrinkles," edited by Mr. H. C. Abell, deals in like manner with minor problems of the business and in 117 pages gives a profusion of useful data.

The last three days, June 9, 10 and 11, were spent at Colorado Springs, in sightseeing and pleasure, the business of the convention having all been transacted in Denver.

Following are the officers elected for the ensuing year: President, Mr. W. H. Blood, Jr., Seattle, Wash.; first vice-president, Mr. Arthur Williams, New York; second vice-president, Mr. Dudley Ferrand, Newark, N. J. The following gentlemen were elected members of the executive committee, to serve three years: Mr. Charles L. Edgar,

Boston; Mr. John Martin, San Francisco; Mr. Frank W. Frueauff, Denver. Mr. L. A. Furguson, chairman of the nominating committee, stated that formerly the secretary-treasurer was appointed by the executive committee, but as this officer is no longer a salaried employe, he suggested that it would be a complimentary action for the convention to elect him. Acting upon the suggestion, Mr. W. C. L. Eglin, of Philadelphia, was elected secretary-treasurer.

CITY REFUSE AS FUEL IN ELECTRIC PLANTS.

BY GEORGE E. WALSH.

The utilization of city garbage and refuse burned in modern dust destructors for the generation of electricity appeals with particular force to municipal authorities where geographical conditions make the disposal of street cleanings costly and cumbersome. English towns and cities have been far ahead of American municipalities in experimenting with combined dust destructors and electrical-generating plants, and the pioneer experimental work performed abroad throws considerable light on the problem for engineers in this country. For upward of three or four years now about fifty towns in Great Britain have had in operation combined dust destructors and electrical works, and of the remaining 120 towns that dispose of their garbage in destructors a fair percentage are making plans to combine electrical plants with their incinerating works.

Eight years ago consulting electrical engineers were opposed to such combinations of destructors and electrical-generating plants, but to-day in England very few offer objections to utilizing refuse as fuel for generating electric light or power. The chief consideration is to find some more economical method of burning the refuse so that as many heat units as possible are utilized, and the experiments conducted furnish abundant data to indicate certain lines of improvement important to the electrical industry. It is fair to assume in the light of experiences with dust destructors and electrical plants in England that within the near future few first or second-rate American cities will waste their refuse by dumping it in the ocean or by burning it in incinerating plants which do not utilize any of the heat. The dust destructor that furnishes steam power either for direct mechanical purposes or for generating electricity will become the rule instead of the exception in American cities.

Refuse of cities is low-grade fuel, inferior to coal, but with certain important steaming qualities. Its heat value varies considerably at different seasons of the year, and even from day to day. The average refuse of a city is much less valuable for fuel in summer than in winter, and on wet days it comes to the destructors in such a condition that it lowers the temperature of the furnaces if fed directly to them.

In consequence of this variable value of refuse as fuel the use of coal together with the garbage and sweepings has been found universally necessary. In the early days of the dust destructor the opinion prevailed in some quarters that eventually the refuse of cities would be burned in destructors without the use of any coal at all, and that the steam or electric power thus obtained would represent a distinct gain of the city, minus the fixed charges on the cost of the plant and the labor of handling and operating it. One of the largest and most important combined plants was constructed in England with this idea in view, and its subsequent history is interesting. The Shoreditch plant in London was erected with the idea that there would be sufficient refuse to supply electric light and power for public purposes without the use of coal. To-day, instead of depending upon refuse alone, this plant is one of the largest users of coal of any in London or the suburbs. Last year 6,376 tons of good Welsh smokeless coal was burned in the destructors and 25,729 tons of refuse. This was due to the fact that the electric station load increased much more rapidly than the supply of refuse fuel, and in order to secure uniform power coal had to be burned at various times.

Since the Shoreditch experience few, if any, destructors and electric plants have been built for the consumption of refuse alone, except on a small scale. The use of both coal and refuse is considered absolutely essential, and even where small plants have been constructed for burning garbage alone it has been found that in the second or third year the load increased so that coal had to be added to the garbage.

With the question of the relative low fuel value of refuse, engineers have had to consider the problem of feeding the fires with such a clumsy fuel as city refuse. Instead of being a compact fuel, the refuse is bulky and oftentimes unwieldy. Feeding such fuel is difficult and wasteful under ordinary conditions. When dumped into the cells in bulk the large mass ignites much slower than coal, and while the leveling and spreading process proceeds the cell grows cool and inactive. When fed with hand shovels the mass of material releases heat units faster, but its consumption is very much quicker than more solid fuel like coal. Mechanical stoking machinery which will feed the cells uniformly and without cooling off the combustion chamber has been found not only economical but absolutely necessary in order to obtain much profit from burning city refuse.

Various types of cells, boilers and combustion chambers have been used in England to overcome the difficulties caused by the nature of the fuel, and the designing and arrangement of the dust destructors and the electrical works represent ingenious application of principles to an end that are of instructive importance. The early types of dust destructors had a low rate of combustion, and, limited by natural draft, the temperature of the gases entering the boiler-heating passages rarely exceeded 800° Fahrenheit, and more frequently averaged 600° to 700°. In the improved dust destructors of to-day the gases enter the boiler tubes or passages at a temperature of 2000° or more, with a minimum temperature of about 1600°.

This remarkable improvement has been obtained either by arranging the fuel cells in pairs so that one is always working actively while the other is being charged and clinkered, or by having a continuous grate with divided ashpits. Both of these types are now in use in England. The former is arranged so that the boiler is placed between two cells, with one combustion chamber common to both cells. The gases from the two cells then mingle in the main flue, and when one cell is cooled or inactive through charging and clinkering the other prevents rapid cooling of the combustion chamber. In this type of destructor one cell may be quite cool while the other is filled with gases at very high temperatures.

Where there is installed a continuous grate with divided ashpits, such as the Meldrum system in use in England, a single cell of some 100 square feet of grate surface supplies heat to the combustion chamber. A separate ashpit for every 25 feet of grate divides it into four compartments. When one division is being charged and clinkered the hot gases from the other three pass into the combustion chamber without being materially affected by the single one out of use. Three-fourts of the large single cell is thus kept in active operation at all times, and no great volume of green gases is ever permitted to enter the combustion chamber at one time.

The application of the regenerative system of supplying heated air for combustion to destructors promises also to add materially to the advantages of refuse burning. This system maintains a very high temperature when coal is burned, and it should prove even more economical when refuse is used as fuel. The use of heated air tends to increase the efficiency of the fuel and promotes rapid ignition, insuring a continuously high temperature. The use of the regenerator with the dust destructor is of particular value in rainy weather when the refuse comes in very moist. The application of some system for heating and drying the wet fuel is one of the problematical features now being tried out.

The actual destroying capacity of the destructors in operation in England with which electrical-generating plants are combined averages nearly 2000 tons of refuse daily. The largest destructors are considerable consumers of coal, and they are adapted to various uses, such as electric lighting, pumping water, heating plants, etc. The largest consumer of refuse in connection with an electrical plant is the destructor at Stepney, London, which burns between 40,000 and 45,000 tons of city garbage and refuse a year, together with about 2350 tons of coal. The proportion of coal to the refuse burned is small at this plant, but coal is used here only to aid the destruction of the refuse and not for generating steam for other purposes. The total number of units developed from the refuse consumed at the Stepney plant are nearly 1,200,000 in round numbers, and about 750,000 units from the

coal. The average number of units obtained from burning the refuse for the year was 28.3, and the highest for a week or more continuous burning in winter 40 units. The whole amount of steam generated by the plant is used for operating the clinker hoist in connection with the destructor, a disinfector and the electric-generating plant. The electric plant is located some 200 feet from the destructors and is supplied with steam through piping.

The destructor furnaces are composed of 12 Manlove-Alliott cells and six Babcock boilers. The furnaces are supplied with forced draft by steam-driven fans, and steam also operates the clinker-hoist independent of the electric plant. No economizers are used at the Stepney destructors, and no other machinery is operated by steam direct.

The engines of the electric-generating plant receive steam through the 200 feet of piping from the destructors; high-speed, vertical, non-condensing engines drive the generators, most of the exhaust steam being utilized for heating the feed-water. There are two generating sets; one set is run continuously throughout the day on destructor steam and the other during the night when the load is at its height. In the past the full supply of steam has not been consumed by the electric plant, and during light loads a good deal of surplus heat has been wasted up the chimney. The plant was designed, however, to accommodate the needs of the community in the future as well as at the present time, and the waste of heat will cease as soon as the demand for the electricity catches up to the output ability. During the hours of heavy load when the supply of refuse runs short, coal is used in the destructors.

The Stepney plant has proved satisfactory since its combination with the electric works, and further improvements are being made to extend its usefulness and cut down the cost of production. One of these is the construction of a new chimney, the old destructor chimney proving inadequate; it is also intended to install economizers. Three extra boilers have been put in during the past year, also new pumps and a water-softening plant. In its practical workings the Stepney plant has come out second best in the matter of costs, and with future economies through contemplated improvements a further saving may follow.

Taking the destructors in the order of the amount of refuse annually consumed, the combined destructors and electrical works at Hackney stand second to the plant at Stepney. About 34,000 tons of refuse are burned in the Hackney destructors, and with only 1255 tons of coal used in addition, the output stands unusually high. The total from refuse and coal stands at about 1,256,000 units, with nearly 125,000 used for operating the fan motors. The steam generated at this plant is used solely for driving electric generators. The destructors consist of three four-cell groups, with a combustion chamber between each two pairs of cells, which leads direct to the settings of three Babcock boilers. The generating plant consists of high-speed engines and direct-current generators, with a 1200-kw.-hour Tudor battery. The highest record obtained at the Hackney plant has been 60 kilowatt-hours per ton. The destructor costs have been found high, the chief items being high wages and the high cost of disposal of the clinker. In fact, disposal of the clinker has proved the most expensive item in the past in nearly all of the destructor plants. The problem of reducing this cost has in a few instances been satisfactorily solved. If the clinker can be sold as a by-product at a small profit or at cost of removal, the destructors would prove far more profitable than they are now. A large proportion of the total costs of the destructors has been caused by operating the clinker-working plant and disposing of the by-product afterward. At the Fulham plant two years ago the cost of the disposal of the clinker amounted to nearly $2400 and at Hackney $3750. At both of these plants arrangements have been made which will eliminate this item, and the cost of operation will thus be materially reduced. The clinker proves of sufficient value in some parts of the country to justify its being removed by contractors at cost. The Hackney plant has a good deal of surplus steam and electric power in the daytime which has had no adequate market, and as a result the showing of this plant has not been as satisfactory as some of the others. With a more favorable market for steam the plant should earn a profit that to-day is lacking.

The Fulham destructor and electrical works burn over 30,000 tons of refuse annually, supplemented by nearly 2,000 tons of coal. As the most economical combination plant in London, its operation is interesting. It has a market for a good deal of its surplus power and operates by steam a disinfector, a clinker-working plant and a brick-making plant. It develops on the average 26.2 kilowatt-hours per ton of refuse. The combination of destructors and electrical generators represents advanced engineering ideas, and the results amply show their practical value. Further improvements are being constantly made, such as the recent installation of a 30-h.p. Bellis steam engine for operating a fan at the base of the chimney stack to increase the draft, and the addition of three marine-type, dry-back destructor boilers.

The destructors consist of 12 Horsfall cells. These are arranged in groups of six each, with three in each group placed back to back. Six Babcock boilers are placed between these groups, and also the new marine-type boilers. Economizers are provided in the main flue, and mechanical stokers in the furnace. Furnace blast was originally supplied solely by steam jets of the Horsfall type, but more recently the Bellis engine operating a fan blower has improved the draft. This engine takes some 30 pounds of steam per brake horse-power-hour.

The electrical plant is of the two-phase alternating type, and the engines driving the generators are of the horizontal Musgrave type, running non-condensing. There are three 300-kw. alternators and three 100-kw., direct-current dynamos, the latter being employed for lighting the works, exciting the alternators and supplying current to motors which drive nearly all of the auxiliary machinery. Two 5-h.p. motors are used for driving the economizer scrapers and four 10-h.p. motors for operating the mechanical stokers and coal conveyors. Besides lighting the place and other public buildings, a good deal of the electric power is used for pumping. There are five 20-h.p. motors driving centrifugal pumps and one 20-h.p. motor driving a deep-well pump. The amount of steam furnished to the brick-making plant has not been stated, but it must be considerable, for it is in operation most of the time in the day.

In the winter season the electric light load is heavy and the full output of the plant is used. During the midwinter holidays some 100 extra arc lights for street lighting are added to the regular plant. The returns from this plant indicate a profit sufficient to warrant its enlargement and the tendency is to improve its efficiency in every possible way.

The Shoreditch plant burns about 26,000 tons of refuse a year and over 6,300 tons of coal and supplies light, heat and power for the public baths, library and deep-well pumps. The disposal of the clinker is an important item here as elsewhere, and it continues to show a considerable loss each year. If this could be eliminated the showing of the plant would be much better.

The Bermondsey plant burns between 13,000 and 15,000 tons of refuse a year and 400 tons of coal. The power is used for generating electricity for lighting and steam used for heating the bathhouses and public buildings. At Woolwich a disinfector and brick-making plant are operated in addition to the generator of electric light for the buildings. Most of the destructors in the smaller places are of the old type, and few of them have been equipped with the most recent improvements. The results obtained from them have little bearing upon the larger problem of reducing the cost of destruction and increasing the output of power and electric light from a given ton of refuse. The average cost of each ton of refuse burned varies in the provinces and in London because of the difference in the price of labor. In London, however, mechanical appliances for economizing in handling and burning apparently more than offset any difference in higher wages paid.

The Value of Tail Rods.—A suburban railway company has as a part of its equipment two 1000-h.p. cross-compound condensing Corliss engines, the engines being both alike excepting that one has tail rods. The engine with the tail rods has been the more economical of the two, and has cost practically nothing for maintenance during the two years it has been running. A saving in steam consumption has also been one of the features of this engine with the tail rods, and it can be run at about 10 per cent greater capacity than the other. In the three years which the engine without the tail rods has run, it has worn out two sets of bull rings and the low-pressure cylinder has been worn down about 1 1/16 ins.

Abstracts from Foreign Contemporaries

Beck Arc Lamp.—The *Elektrotechnische Zeitschrift* contains an illustrated description of a new arc lamp in which the carbon is impregnated with light emitting substances and which burns with a long arc. The construction of the lamp is shown diagrammatically by Fig. 1. The carbons are arranged side by side in a slightly inclined position. One carbon is fixed, with respect to its longitudinal direction; the other being adjusted in position by means of the lever shown at the top. This lever is operated by means of an electromagnet, shown in the center at the top of the lamp. When no current flows the two carbons touch each other at their terminals at the bottom. When

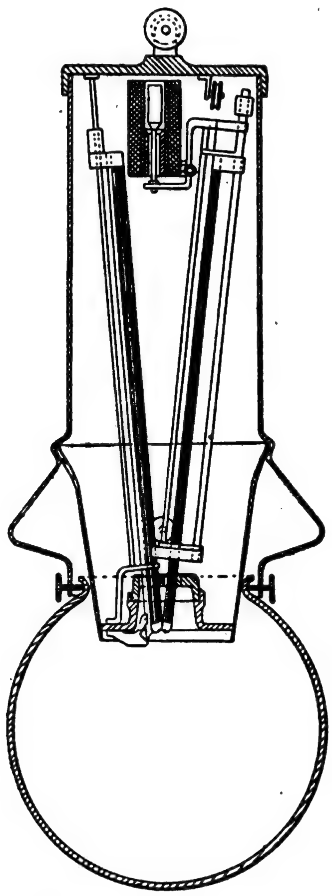

FIG. 1.—BECK ARC LAMP.

the circuit is closed the right hand carbon is deviated sideways and the arc is started. The deviation of the right hand carbon is limited so that a constant distance between the two carbons is maintained. The electromagnet is entirely closed and contains only a few windings through which the main current flows. The lower terminals of the carbons are surrounded by a cast-iron reflector, the inside of which is of white enamel. The left carbon (for direct-current mostly the positive carbon) has not an exact circular cross-section, but is provided with a rib, which is shown at the left, and by means of which it rests on a support mounted at the bottom of the reflector. Above the lower supporting surface there is provided a small chamber surrounding the carbon rib and protecting it from the air. The purpose is to let the carbon burn off in such a way that a fine point always remains at the end of the rib. This fine point is the point on which the left carbon rests. It is stated that it burns off very uniformly and slowly, so that the carbon electrode is fed downwards very gradually and uniformly.

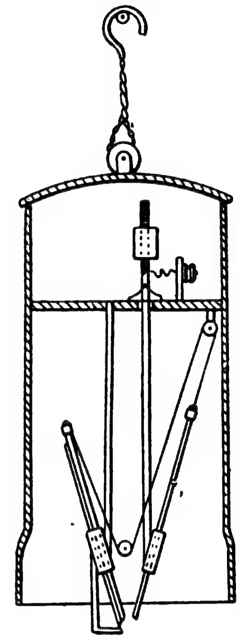

FIG. 2.—BECK ARC LAMP.

The support on which the fine terminal point of the carbon rib rests remains relatively cold. The right hand carbon, which has a completely circular cross-section, is fed downwards simultaneously with the left hand carbon by means of the mechanism shown in Fig. 2. The most economical current is stated to be 6 to 12 amperes for direct or alternating current for an e. m. f. at the terminals of 42 to 46 volts. Wedding has tested a direct-current lamp for 9.1 amperes at 44.2 volts, which gave without globe, 2469 hemispheric candle-power, corresponding to a consumption of 0.163 watt per candle. The maximum of illumination, which is 3800 candle-power, is perpendicularly below the lamp. Cored carbons are stated to be best. For the 9-ampere lamp the diameter of the positive carbon is 8 mm., that of the negative carbon is 7.5 mm. The length of the carbon is 330 mm. for the smallest type of lamp, which gives a carbon life of 8 hours. The lamps are built for carbon lengths up to 550 mm. For a carbon life up to 30 hours double lamps are used.

Electrical Resistance of Steel.—The May *Bulletin* of the Société d'Encouragement pour l'Industrie Nationale contains a short but interesting article upon the "Electrical Resistance of Steel." Following up some experiments made some time ago by Monsieur H. Le Chatelier, the author of this article—Monsieur P. Mahler—has carried out a series of tests on specimens of steel containing varying amounts of carbon, manganese, sulphur, phosphorus and silicon. Generally speaking, he has established the fact—which in truth is what might have been expected—that the more impure the steel, the higher is its electrical resistance. For example, in one of his sets of experiments he took five test pieces, varying from soft steel, with a breaking stress of 40 kilos. per square millimetre of cross-section, to hard steel with a breaking stress of 70 kilos. The percentage of carbon varied from 0.16 per cent. to 0.62 per cent., and of manganese from 0.70 per cent. to 0.80 per cent. The observed resistance was 14.6 microhm-centimetres for the soft steel and 18.0 microhm-centimetres for the hard steel. M. Mahler found that the total resistance varied in accordance with the formula $R = 10 + 7\,C + 5\,Mn$; where C is the carbon, Mn the manganese, and 10 the resistance due to the iron and to the other impurities, such as sulphur, phosphorus, etc. The 7 and 5 for carbon and manganese were the figures which M. Le Chatelier had found in his experiments. The coefficient 10 has been found by M. Mahler, and within the limits of his investigations the formula appears to give the resistance of any steel of known composition very fairly nearly. There are discrepancies, which are sometimes on one side and sometimes on the other, but in a number of cases the calculated resistance was found to be the same as that which was obtained by measurements. Perhaps the balance lies rather in the direction of the coefficient 10 being somewhat high, but this error is certainly on the right side. The ability to estimate the electrical resistance of steels of known composition within a reasonable degree of accuracy is highly important having regard to the increasing use of steel rails for conducting electricity, and it would appear that in samples of metal known to be more or less oxidized or more or less gaseous, the actual resistance is less than what might be looked for if the above formula is taken as a basis. This means that, at any rate, the probabilities are that a calculation of the resistance is more likely to err on the high than on the low side.

The Lentz Engine.—A neat type of engine, manufactured by Les Ateliers de Construction, H. Bollinck, of Brussels, is described in the London *Engineer.* The engine, which is of massive design, works with superheated steam of high temperature. The cylinders are placed tandem, and directly connected to each other so that one stuffing-box is dispensed with. One stuffing-box is placed between the two cylinders. Steam enters from the boiler at the bottom side of the high-pressure cylinder, and leaves through the exhaust valve, and then passes directly into the low-pressure cylinder, of which the admission valves are placed on the top, and the exhaust valves at the bottom. By this system it is claimed that the steam follows a rational and short course, and the important losses produced by radiation and condensation in the pipes

and receiver are by this means avoided. Joints in pipes are also dispensed with, and it follows that there will be no expense in maintenance in respect of these. Another point claimed is that the fall in pressure between the two cylinders is not so great in this case as it would be with piping and a receiver. One of the most interesting features of the Lentz engine is the valves. The admission valves are double seated, the interior seat being smaller than the other, the whole system being balanced. They are capable of lifting automatically should any water get into the cylinder. The valve seats are of such a shape that when the valves are closed they form a water-tight joint. The valve rods are fitted with a roller actuated by an eccentric on the gov-

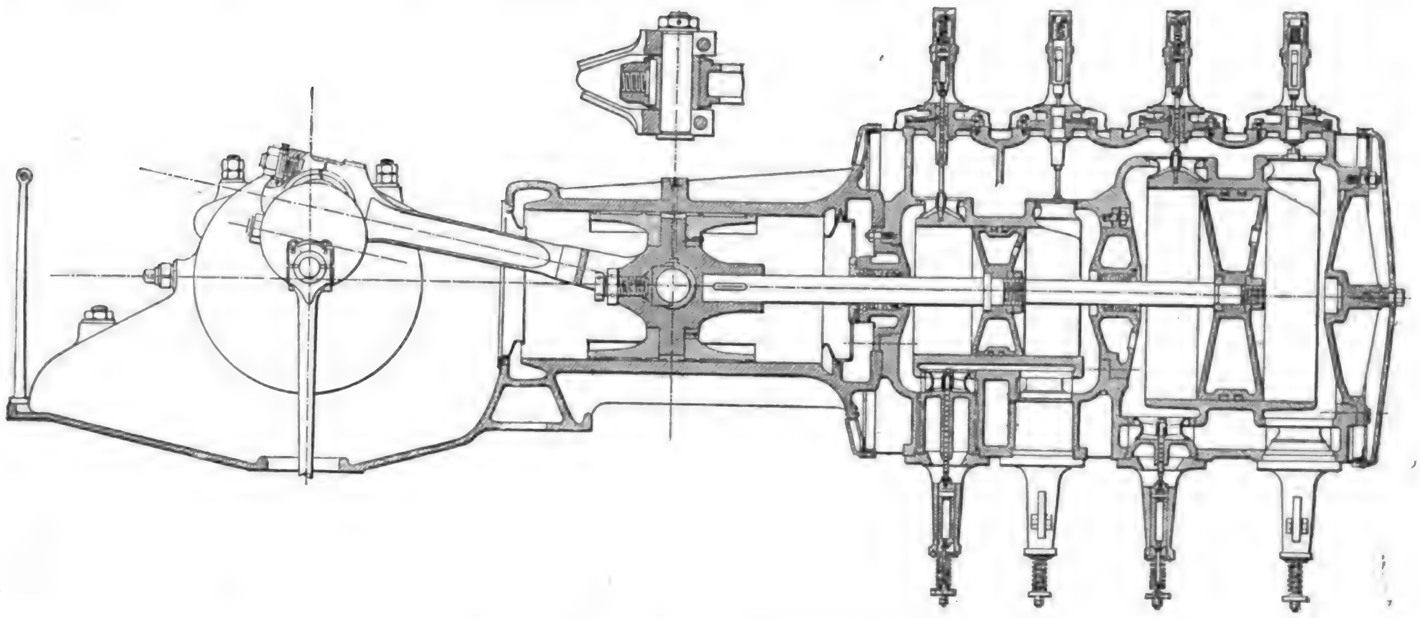

FIG. 3.—LENTZ TANDEM COMPOUND STEAM ENGINE.

ernor spindle on which are two eccentrics connected by two rods to the cams, against which the rollers of the valve spindles are kept pressed. The valve rods receive their motion from these cams, and the design of the latter is such that a rapid opening and closing can be obtained without any shock. The Lentz governor is said to be very sensitive. As will be seen from the illustra-

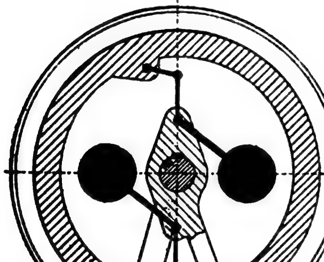

FIG. 4.—LENTZ GOVERNOR.

tion, the governor consists of a ring which acts as a sort of fly-wheel. There is a boss on the governor spindle, and on both the ring and the boss there is an arm, these arms being joined together by a circular coupling spring. The boss is oblong in form, and to it are pivoted the weight spindles, the ends of which are connected by links to lugs placed exactly opposite one another on the inside of the ring. As soon as an acceleration of velocity is about to take place, the inertia of the ring absorbs part of the load on the circular coupling spring, and the centripedal force is diminished. The weights immediately separate, and the valves are acted upon. Exactly the opposite to the foregoing happens when the engine tends to run slow. The variation of the amount of admission of the steam to the cylinder is said to precede any visible change of velocity. The effect of the inertia of the fly-wheel ring is only momentary, and disappears when the velocity becomes normal. The makers state that the governor acts so well that polyphase generators may be run in parallel without any fear of uneven loading. The governor can be so arranged that the speed of the engine can be regulated from the switchboard. The stuffing-box is also another interesting part of the engine. It is formed by a series of annular recesses in gun-metal rings, the rings having placed between them cast-iron rings, which are an easy fit on the rod. The recesses are filled with oil The first ring allows some steam to escape, the second one absorbs part of this escape, the third does the same, and finally the fourth ring allows no steam at all to escape. The small quantity of steam which is introduced at the moment of admission into the first two or three recesses returns to the cylinder during the period of expansion. The valve spindles have no stuffing-boxes. They are ground in their guides, and carry a series of small annular cavities, which retain a layer of oil mixed with condensed water. This arrangement is said to be particularly advantageous when superheated steam is used. The stuffing-box for the piston-rod, and also for the valve spindle, involve practically no metallic friction, and, for this reason, the makers assert that the loss of power due to these parts is small. It is stated that the variation in speed of these engines in any one revolution does not exceed 1.25 per cent. The makers have adopted a short stroke which is not much more than half what is usual in other engines of this type, and this allows of a considerable increase in speed without the piston speed exceeding about 4 m. per second. There is only one spring, and no delicate mechanism or dash-pot. Sight feed lubricators are employed for oiling the various parts of the engine.

Wireless Telephony.— Dr. Hugo Mosler contributes to a recent number of the *Elektrotechnische Zeitschrift* some observations made by him while experimenting in wireless telephony. The simplest arrangement of sending station is shown by Fig. 5 herewith, where B is a battery having an e.m.f. of about 25 volts, M is a microphone, and J an induction coil one secondary pole of which is connected to earth. The telephone used at the receiving station has one terminal connected to earth, while the other terminal is free. The telephone used by the author in his experiments had a metal box which was touched by the hand of the hearer. The use of antenna at the receiving station does not improve transmission. For good transmission it is preferable to connect at the transmitting station the free secondary pole of the induction coil with an insulated suspended coil S containing about 2.5 km. of copper wire. If both poles of the induction

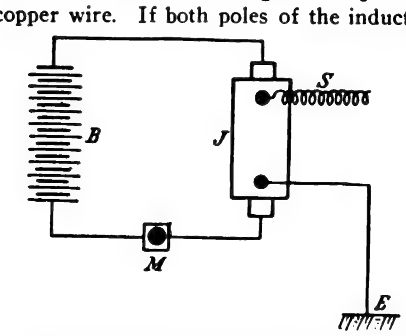

FIG. 5.—WIRELESS TELEPHONE SENDING STATION.

coil J are earthed, the transmission of sound is greatly weakened. On the other hand if both poles of the telephone are earthed at the receiving station good sound transmission results if the conditions are as indicated in Fig. 6. In this engraving A represents the earthed plate of the induction coil at the transmitting station; $B\ C\ D$ are earthed

plates at the receiving station, F is a telephone and E a switch, by means of which either plate C or D may be connected to F. With B and C connected to F no sound is received; but with B and D connected to F the transmission of sound is good. The author accounts for this by assuming that

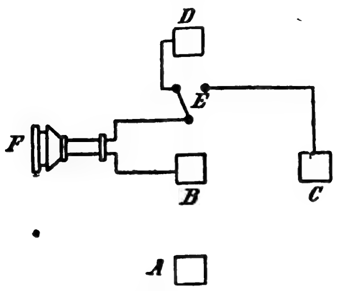

FIG. 6.—WIRELESS TELEPHONY.

periodic electrifications of the surface of the earth are propagated from the earth plate A of the transmitter. This propagation takes place in circles around A. In order to get good transmission, therefore, it is necessary to connect the telephone F with two points having different potentials. If B and

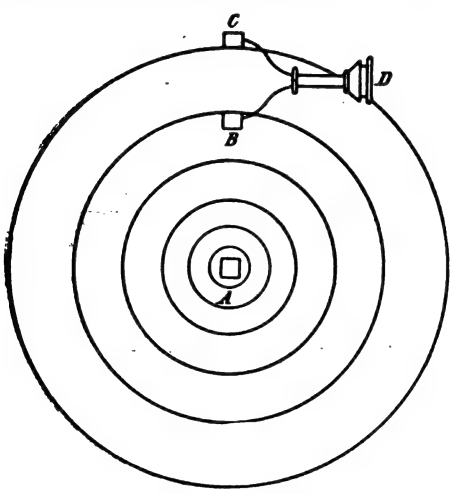

FIG. 7.—WIRELESS TELEPHONY.

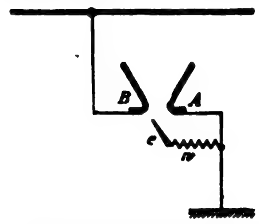
C are about equally distant from A they have about the same potential, so that nothing is heard in the telephone D. In the experiments only one pole of the telephone was earthed, but a second earthed connection was made through the metal box of the telephone to the experimenter, who in this case was standing at a point D. Sound may thus be transmitted over several kilometers, especially over water, if induction coils with high transformation ratios and a microphone which can stand strong currents are used. For wireless telephony over greater distances, however, it is, of course, necessary to use ether waves.

Lightning Arresters—Alberto Dina contributes to a late number of *Elektrotechnische Zeitschrift* an illustrated article on various designs of lightning arresters with particular reference to the relay built by the Siemens-Schuckert Works. The most suitable length of air gap for relative low voltages of a few thousand volts is said to be three to four millimetres. All attempts to lengthen the air-gap by giving special forms to the electrodes, as for instance by giving them sharp edges, have proved unsuccessful, since after numerous discharges have taken place the sharp edges are destroyed. Artificial air-gaps have been introduced in many instances for the purpose of starting the discharge. Either the heat effect or the ionizing effect of the ultra-violet light of the stroke starts the discharge through the main air-gap. Fig. 8 shows such an arrangement in which Be is the auxiliary air-gap, and BA the main air-gap. A modification of this arrangement is shown by Fig. 9, in which three discharges may take place; first between ee, then between B and e and finally the main discharge from B to A. Further modifications of this scheme are, of course,



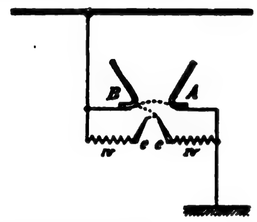


FIG. 8.—LIGHTNING ARRESTERS.—FIG. 9.

possible by using successive auxiliary gaps like that at ee, one below the other and with decreasing lengths of the gap so that the lowest and shortest gap is first acted on. This starts the discharge through the next one above and so on. The disadvantage of this arrangement is that the auxiliary air-gap must have a short length and is liable to be changed in time, and the wind may, moreover, blow the discharge from the main gap to the auxiliary gap, and it may remain where there are no special devices provided for extinguishing the arc quickly. The Siemens-Schuckert lightning arrester is shown by Fig. 11. The device makes use of a special circuit in which high frequency oscillations are produced. W is the damping resistance and $B\,A$ is the main air-gap. $C\,C^1$ are condensers, F is an auxiliary air gap, P

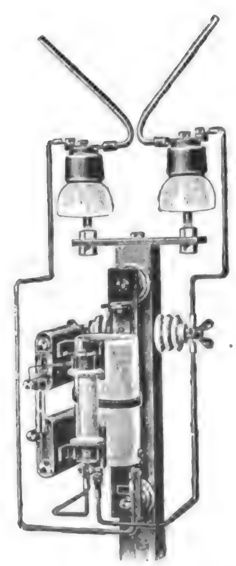

FIG. 10.—LIGHTNING ARRESTER.

the primary and S the secondary of a transformer. When the voltage at the plates of the condenser C (which is practically equal to the voltage between line and earth) reaches the value to which the air-gap F is adjusted, the condenser C discharges partly through the circuit $C\,F\,C^1\,P$, i. e., it transfers a part of its charge to the other condenser C_1, high frequency currents being produced. This discharge depends in no way on the methods by which the condenser C has been charged (that is, on the causes of the excessive rise of voltage in the line). The oscillating currents in the primary P

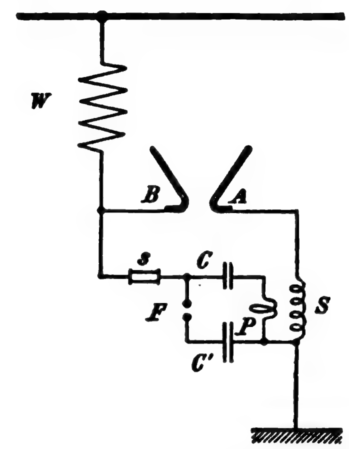

FIG. 11.—SIEMENS-SCHUCKERT LIGHTNING ARRESTER.

produce a high e.m.f. in the secondary S of of the transformer, so that now a higher voltage exists between B and A and the discharge from B to A is started. This higher e.m.f. does not affect the line. The main advantage is that there is no direct effect from the auxiliary air-gap F on the main discharge gap BA. It is, therefore, possible to enclose F in a suitable tube and place it at some distance from the main discharge. The apparatus is called a "lightning arrester relay." It is built with an air-gap $B\,A$ of 4 mm. for about 3000 volts effective current and with a gap of 3 mm. for about 2000 volts. Fig. 10 shows the relay in use with horn lightning arresters. A modification of the arrangement shown in Fig. 11 is given by Fig. 12. In this arrangement the condensers are placed in series instead of in parallel as in the former case. The arrangement, however, has the disadvantage that the condensers are always under tension; but, on the other hand, it has the ad-

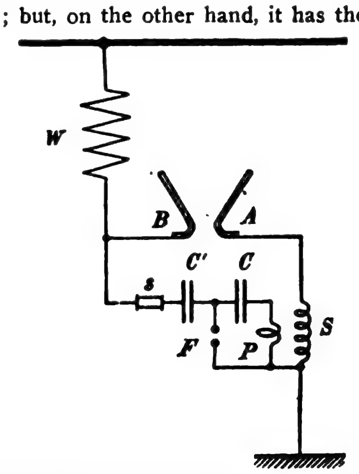

FIG. 12.—SIEMENS-SCHUCKERT LIGHTNING ARRESTER.

vantage that each condenser has to stand only part of the tension. For adjusting the auxiliary air-gap only the voltage of the condenser C has to be taken into account. For this reason this latter arrangement may be used for higher tensions. Fig. 13 shows an arrangement having many different

spark-gaps but requiring but one arrester. In this scheme no condenser is under tension for any length of time. If the arrester itself has not acted on the appearance of over voltage, it is at least probable one of the air-gaps, *f*, will get into action so that the condensers $C\,C^1$ are charged. This process of charging through a sparking distance cannot produce any considerable e.m.f. since the capacity of the condensers may be very small and are connected in series with the damping resistance *W*. Owing to the sensitive adjustment of the air-gap *F* of the oscillating circuit the condenser *C* begins to discharge at the beginning of the condenser charge, so that the arc, therefore, begins to discharge at once. The e.m.f of the secondary *S* does not any longer discharge through the oscillating circuit itself; since, however, the object of the relay is not to enlarge the gap but to start the discharge, a very small capacity γ is sufficient to cause a higher e.m.f. to be established between the horns of the arrester than that for which the arrester was adjusted. By this means the machine is protected by the high self-induction of the choking coils. There remains, however, the greater capacity *T* between the line and earth in series with the arrester and the resistance *W* which offers an easy return path for the oscillations passing from *S* to the arrester.

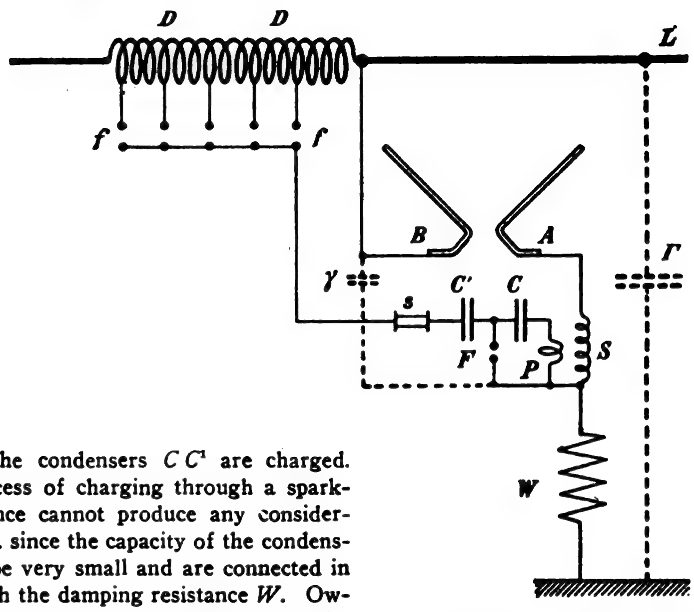

FIG. 13.—LIGHTNING ARRESTER.

Efficiency of Switches and Switchboards.—A. Boje contributes to the *Elektrotechnischer Neuigkeits-Anzeiger* an account of an extended series of tests on switches and switchboards. The station contained two 80-kw., direct-current dynamos, one of 160 kilowatts and two storage batteries each of 600 ampere-hours. The mean current of the machines and batteries during one year was carefully determined and the efficiency of the switches and the switchboards was then calculated for this mean current. The total energy given out during one year from the switchboard was 298,546 kw.-hours, the loss in the switchboard 2404 kw.-hours; hence the efficiency was 99.2 per cent. While this efficiency is high, yet the selling price of the energy lost during one year in the switchboard represents 20 per cent of the first cost of the switchboard. The author discusses means for decreasing this loss. He recommends strongly the avoidance of ordinary electromagnetic measuring instruments in switchboards, and the installation of precision instruments in spite of their higher cost, since the saving due to the decreased loss in only two years compensates for the higher cost. A great many experiments were made on the loss in movable contact surfaces. Fifteen different lubricating materials were tested and it was found that a certain fat which conducts the electric current reduced the losses in the contacts by 50 to 60 per cent. Other fats were not as good and some materials tested, like stearin, tallow, graphite, increased the contact losses. It is, therefore, recommended to lubricate the movable contact surfaces very slightly with a suitable fat. Stationary contact surfaces, for instance bus-bar connections, etc., also showed considerable losses. From a great number of tests with various thin plates placed between the two contact surfaces it was found that the contact loss can be slightly reduced by a thin sheet of tin-foil of 0.02 mm. thickness or of copper of 0.04 mm. thickness.

Some Recent Electrical Patents

Mercury Vapor Lamp.—In the construction of electric lamps of the mercury vapor type it is essential that some means be provided for breaking down the initial insulation of the space within the tube in order to start the flow of current through it. The devices hitherto employed for this purpose have involved the application of a high e.m.f or else necessitated the use of some magneto-mechanical arrangement for putting the electrodes momentarily into contact; the latter class of apparatus appears to be gaining in favor. A very simple arrangement of this class has been devised by Mr. W. R. Whitney, of Boston, Mass., in which the moving parts are all outside the lamp proper. This is illustrated diagrammatically by Fig. 1, in which 2 is the upper electrode, 5 is a carbon filament extending downward from the electrode to within a short distance of the mercury, 3; 7 is a glass support for the filament, 8 is a magnet coil and 12 is an automatic cut-out for this coil. The mass 3 is an amalgam of mercury and iron, so that it is capable of responding to the magnetic attraction of the coil, 8, when that coil is excited; the mercury and iron are then drawn up into contact with the carbon filament, as indicated at the lower right hand corner of the engraving, and the current is thereby started through the lamp. This

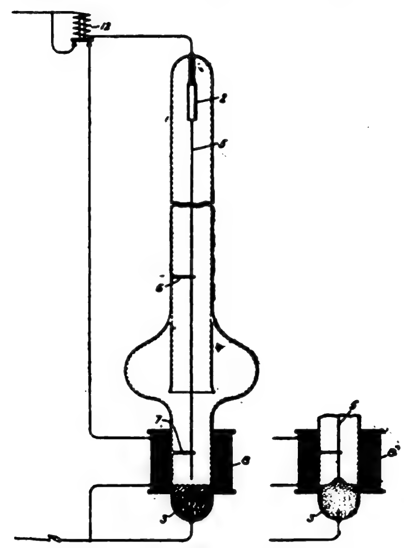

FIG. 1.—MERCURY VAPOR LAMP.

energizes the magnet of the cut-out, 12, which opens the circuit through the magnetic coil, 8, allowing the mercury to fall back away from the carbon filament and start the arc. The arc follows rapidly along the filament until it reaches the upper electrode, when the lamp is is full operation. Patent No. 792,639.

Contact Key for Alternating Currents.—An objection to the use of a contact-making and breaking device in a circuit carrying heavy current is the arcing that occurs between the active faces of the contact pieces when the circuit is broken. It is obvious that in the case of alternating current of symmetrical wave form, arcing at the contacts could be prevented if the circuit were opened exactly at the instant when the alternating e.m.f is passing through zero. Fig. 2 illustrates in simplified diagrammatic form an arrangement devised by Mr. Andrew Gray, of London, for accomplishing this, and Fig. 3 indicates a modification. In Fig. 2, the finger piece, *g*, when depressed holds the contact lever *d* against its anvil, regardless of circuit con-

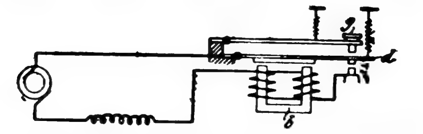

FIG. 2.—CONTACT KEY FOR ALTERNATING CURRENTS.

ditions. When the finger piece is released to open the circuit, the magnet *b* retains the lever *d* until the alternating current reaches zero, when the lever is free to be drawn away from the anvil by the spring. In Fig. 3, there are two contacts in shunt relation, one controlled by the key *g* and the other independently controlled by the arma-

ture *d*, which vibrates in unison with the alternations of the current, but cannot open the circuit as long as the shunt key contact is closed. Releasing the key leaves the cir-

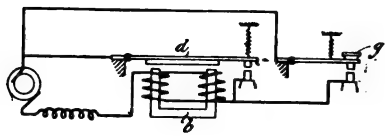

FIG. 3.—CONTACT FINGER FOR ALTERNATING CURRENTS.

cuit dependent on the armature contact, of course, and it is opened at the next succeeding zero point. Patent No. 702,020.

Alternating-Current Motor Control—One of the most interesting characteristics of the alternating-current commutator motor is revealed in a patent recently issued to Messrs. G. Winter, of Vienna, and F. Eichberg, of Berlin. The patent relates to the use of self-exciting generator features of the repulsion motor; the control circuits are shown in Fig. 4 herewith. The armature winding, indicated by the circle *B*, is close-circuited by two brushes bearing on the commutator in the usual manner and connected electrically by a conductor of negligible resistance. In line mechanically with the brushes is an "inducing" field winding, *A*, and in mechanical quadrature with this winding is an "exciting" field winding, *C*. For normal operation the two windings are connected in series; the armature winding is in inductive relation to the field, as usual. When it is desired to stop the motor, the field windings are disconnected from the supply circuit, of course, and close-circuited in series with each other and the adjustable resistance, *R*, but with their relative connections reversed; this is for the purpose of braking the motor electro-dynamically. In this condition the magnetic flux encircled by the exciting winding induces an electromotive force in the armature windings to which the brush position is favorable, and the current flow-

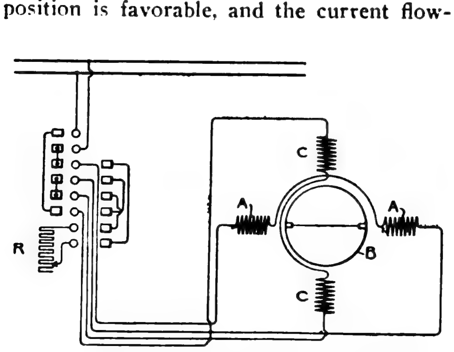

FIG. 4.—ALTERNATING-CURRENT MOTOR CONTROL CIRCUITS.

ing in the armature winding strengthens the magnetic flux within the exciting winding, thereby braking the armature. Patent No. 792.103.

CENTRAL STATION ENGINEERS

IX.

Henry Harbison Sinclair.

Henry Harbison Sinclair was born in Brooklyn, N. Y., on December 22, 1858. His education was begun in the public schools of his native city, after which he entered the Military Academy at Bethlehem, Pa. At the age of 15, however, he ran away from home and shipped on a sailing vessel bound for California, quitting the sea three years after with papers as a second mate. When 18 years of age he took up a scientific course at Cornell University, which he was compelled to abandon owing to failing health. He then entered the New York shipping firm of his father, afterward becoming the latter's partner under the firm name of N. B. Sinclair & Son. In 1885 Mr. Sinclair abandoned business to study law in the firm of Hill, Wing & Shoudy, applying himself to admiralty practice. This, too, he was compelled to relinquish owing to failing health and in 1887 he moved with his family from New York to Lugonia, Cal., a settlement adjoining the town of Redlands, where he engaged in orange culture. For several years Mr. Sinclair led the quiet life of a horticulturist, gradually regaining his health and a longing for active commercial existence. When, therefore, the opportunity came in 1892 to develop a water power plant on Mill Creek, east of Redlands, which should supply electric energy to his city and the surrounding territory, he was quick to see its possibilities and to turn them to advantage. He assisted in the organization of the Redlands Electric Light & Power Company, becoming its president and general manager and continuing the active head of the company until it became the property of the Edison Electric Company. At the time of its transfer the Redlands Company had in successful operation two plants on Mill Creek and a third under construction, having pioneered 10,000-volt transmission, and about to pioneer the discharge of water from a vertical height of 1962 feet into the impact wheels of power house No. 3. This plant has been in operation since March, 1903. In April, 1897, Mr. Sinclair organized the Southern California Power Company, which was transferred to The Edison Electric Company, of Los Angeles, the next year, Mr. Sinclair becoming a director of the latter company. Subsequently there were organized the Lytle Creek Light & Power Company, operating on Lytle Creek, San Bernardino County, Cal., the Mountain Power Company, operating on Santa Ana River, the California Power Company, operating in Kern County, and owning water rights for the development of nearly 100,000 horse-power, and the Kings River Power Company, with water power rights in San Joaquin County. Mr. Sinclair was actively associated in the formation of these companies which afterward became a part of the Edison system.

HENRY HARBISON SINCLAIR.

In the fall of 1901 Mr. Sinclair removed to Los Angeles, having in the meantime become third vice-president of The Edison Electric Company, in charge of all the company's water power development. Mr. Sinclair became the general manager of the company early in 1903, devoting his energies to the details of the expanded corporation. Incessant work again told on his health, and he was obliged to take a prolonged trip to Honolulu and the South Sea Islands, Japan and the Philippines. The war in the Far East, however, changed his plans and he began his return voyage after six months' absence. In 1901 Mr. Sinclair assisted in the organization of the San Bernardino Valley Traction Company, an interurban electric road uniting the cities of San Bernardino, Redlands and Colton and the town of Highlands, operating some 28 miles of standard gauge single track. Mr. Sinclair's company is among the largest electric companies of the United States, supplying electric light and power to 18 municipalities situated in five counties.

NOTES.

New York State Independent Telephone Association held its fourth annual meeting at Albany, June 16. In addition to the reading of papers, the convention passed resolutions to the effect that the State authorities be requested to install independent telephones in the various departments, buildings, etc., so that communication with such departments, etc., might be available to patrons of independent exchanges.

International Association of Municipal Electricians has decided to change the date of its coming convention at Erie, Pa., to August 23, 24 and 25, instead of August 29 to 31, inclusive. Reference was made in this column last month to the excellent character of the papers to be read.

The Southern Hardware Jobbers' Association held its fifteenth annual convention at Hot Springs, Va., June 6 to 9, inclusive. The meeting was conspicuously satisfactory in all particulars; the papers were on live topics and able in character, and the entertainment features left nothing to be desired.

Evening Courses in Physics and Electrical Engineering.—The Polytechnic Institute of Brooklyn announces for next fall a series of lectures on "Electric Transportation" as one of the evening courses in electrical engineering. These lectures will be delivered, beginning October 10, by Messrs. Armstrong, Barstow, Bliss, Calderwood, Doyle, Lardner, Mailloux, Moffatt, Perrine and Stott, all of whom are prominent practising engineers.

Reduction in Price of Current in New York City.—The New York Edison Company announces a reduction in the price of current from 15 to 10 cents per kilowatt. Power rates vary accordingly. No charge is made for incandescent renewals or arc lamp supplies, and all incandescent lamps and arc lamps that have been cut off temporarily or otherwise and all 16-c.p. incandescent lamps that have been replaced by smaller sizes may be restored to service without effect upon the charge.

Tired of Municipal Ownership—A recent special dispatch from Monroe, Mich., says: "The Monroe City Council has apparently become sick of owning a municipal lighting plant. Some two weeks ago a proposition was sprung by City Surveyor White to lease the plant for ten years. Since that time other proposals have been presented and the council at an informal session decided to hear further propositions. The Detroit, Monroe & Toledo Company also made a proposition to furnish power, and this seems to be the most feasible one, since they have plenty of current. A full report will be made by a committee. Monroe has had municipal ownership for five years."

American Institute of Electrical Engineers held one of the most successful and satisfying conventions of its history at Asheville, N. C., June 19 to 22, inclusive. The papers were of a much higher average merit than usual and the proceedings passed off with commendable smoothness. The only departure from the programme as originally laid out was the holding of a short extra night session to dispose of a few papers that could not be given attention at the regular morning session on account of the length of discussions at that session. The lateness of the date of the convention precludes any attempt to publish a report of the proceedings in this number.

Municipal Plant in Oklahoma.—The Union Light & Power Company, of El Reno, has finished the municipal lighting plant at Anadarko, Oklahoma, and turned it over to the city. The plant was built in connection with the water works lately installed by the United States Government engineers, from the proceeds of the sales of the town and city lots at the time of the opening in August, 1901, the sales of these lots being reserved by the Government for the purpose of municipal improvements. The electric lighting plant consists of a tandem-compound McEwen engine 12 by 20 by 16, running at 250 r.p.m., direct-connected to a 110-kw. three-phase Bullock alternator. The street lighting system includes the Jandus alternating-current series arc lamps. The plant is in charge of Mr. A. C. Loudermilk, superintendent, and Mr. Charles Tomlins, chief engineer.

A 10,000, H P. Steam Turbine Installation.—Two steam turbine-generator sets of 10,000 horse-power are being installed at the Rhenanian Westphalian electricity works; these are the largest turbine sets, and in fact the largest stationary engines, in the whole of Europe. Each unit comprises a turbine running at 1,000 r.p.m., an alternating-current generator capable of 5,000 kilowatts at 5,000 volts and 50 cycles per second, and a direct-current generator of 1,500 kilowatts, giving 600 volts. The turbines are operated from a central steam plant. The whole set is 20 metres in length and weighs 190 tons, of which 9.4 metres and 107 tons apply to the turbine. The maximum height of the turbine above the floor is 2.6 metres, and the maximum breadth is the same. The turbine is of the Parsons type and has only two bearings, one of which serves also as bearing for the alternator. The governor is made to regulate to within 1 per cent. for variations in the angular speed, with fluctuations in the load as high as 20 per cent., while the maximum variation in the number of revolutions, between no load and full load, is not to exceed 5 per cent.

Power Development in Tennessee—The big project in the erection of the 36,000-h.p. lock and dam power plant at Hale's Bar in the Tennessee River is considered an assured fact. Messrs. C. E. James and J. C. Guild, the promoters of the scheme, have been in New York, where they completed the details concerning the financing of the scheme. It is announced in this connection that as soon as the plant is erected several new manufacturing plants will be erected at Chattanooga, one of them having a capital stock of over $1,000,000. The promoters will apply for a charter with $3,000,000 capitalization. The following will be the incorporators: C. E. James, J. C. Guild, J. C. Sims, R. H. Williams and George D. Lancaster. The plant will be located 12 miles from Chattanooga. The dam will be built of cement and stone, being 57 feet at the base, 9 feet at the top and 35 feet in height. The gates will cost $150,000 and will be furnished by the Government. The power plant will be located on the east side of the river and will be 60 by 30 feet in dimensions and 57 feet in height. Thirty-six turbine wheels will be employed to drive twelve generators.

Electricity on Board a German Warship.—The liner *Preussen*, which was recently attached to the German Baltic marine station, has a displacement of 13,200 tons and a speed of 18 knots, the output of her engines being 16,000 horse-power. Her equipment comprises four quick-firing guns of 28 cm. gauge, fourteen 17-cm. quick-firing guns and twelve of 8.8 cm. gauge; twelve 3.7-cm. machine guns, eight machine rifles and six torpedo launching tubes. All the rooms as well as the upper deck are lighted by incandescent lamps. For use in connection with the scouting service in battles, and also for signaling to a distance, there are used four large projectors, of 6,000 nominal candle-power each.

Electric motors are used for conveying ammunition from the ammunition chambers to the guns, for moving the rotating gun turrets, handling coal, lowering and hoisting the large boats, operating the machine tools and refrigerating plant, as well as for driving numerous fans of different sizes, which are installed in all the rooms of the ship.

The apparatus for the transmission of orders from one part of the ship to another, as well as for communication between different ships or from land to ship, the medical outfit of the infirmaries, instruments for indicating the depth, etc., are all operated by electricity.

Time Required to Start a Steam Turbine—At the recent Scranton meeting of the American Society of Mechanical Engineers, Mr. A. S. Mann presented a paper giving the result of observations on the time required to start a Curtis steam turbine. The turbine is of 1500 kw. capacity and is supplied from boilers which also supply steam for other purposes; upon starting up the turbine it is necessary, however, to pass from the condition of slow fires to forced fires. The time observed was that from sounding a whistle calling a scattered force to stations, to the time when the turbine was cut into circuit. Three or four pumps must be used in starting off each pair of turbines, and also an exciter driven by a small steam engine. The record book shows that of 43 calls for sudden starting up, 10 starts were made in 2½ minutes, 18 in three minutes and 15 in 3½ minutes. In a number of instances when all of the auxiliaries were in motion, the turbine was started and connected to line in from 45 seconds to 1½ minutes. Two starts in 45 seconds were made on the turbine when it had stood for 24 hours with the throttle valve shut, but with a slight leakage past the seat. After the throttle valve is off its seat it does not require more than 30 seconds to bring a turbine up to speed. The author states that to start a large steam engine from a cold state requires from 12 to 15 minutes and from a hot state 5 minutes.

ESTABLISHED 1889.

AMERICAN ELECTRICIAN

WITH WHICH IS INCORPORATED
Electrical Industries.

CECIL P. POOLE, Editor.

Issued on the first of each month by the

McGraw Publishing Company

114 Liberty Street, New York.

Philadelphia Office..........929 Chestnut Street
Chicago Office ....Monadnock Building
Cleveland Office ....Cuyahoga Building
London Office, Hastings House, Norfolk St., Strand

Address all business communications to AMERICAN ELECTRICIAN, *114 Liberty Street, New York. Matter intended for publication in the reading columns should be addressed to the editor.*

Subscription price, $1 per year, postage prepaid, in the United States, Canada, Mexico and Cuba; $2 in all foreign countries. The date on wrapper shows when subscription expires. Subscribers should give their old as well as their new address when requesting a change in address. This should be received a week in advance of the desired change. No copies are kept on sale beyond fifteen months from date of issue, except in bound volumes.

Advertising rates sent on application. Advertisements received for insertion up to the 25th of the month prior to date of publication. Changes in standing advertisements should be received not later than the 15th of the month to insure their insertion in the next issue.

Remittances should be by check, New York draft, express or postal money order, payable to AMERICAN ELECTRICIAN.

Vol. XVII. JULY, 1905 No. 7

The AMERICAN ELECTRICIAN *has the largest circulation of any electrical journal published. Of this issue, 17,000 copies are printed. The total number of copies printed so far this year is 129,000, or an average of 18,428 per issue.*

CONTENTS.

The Consulting Engineer and the Small Central Station.

Although it is true that many of the most lucrative pieces of work which fall to the consulting engineer are those in which things are done upon a great scale, there is still a field for the practice of thoroughly good engineering in connection with the smaller enterprises like the moderate-sized central station, the isolated plant and the small telephone exchange. In fact, it is a question if in some cases the limited resources of the small plant do not call for a greater degree of skill in meeting emergencies or practising expedients to make the business grow and pay than in the installations backed by millions in capital and surrounded by the facilities and conveniences of a great city.

It requires but a short study of different small central stations operating under modern conditions to show that remarkable differences exist among them in reference to the cost of operation and earning power, to say nothing of the diversity of equipment found. To cite a recent instance, the gross earnings per capita in those Massachusetts central stations serving less than 10,000 inhabitants last year varied from 60 cents to $5.14, and the ridiculous figure of 10.4 cents was reached in one case, if the returns can be considered correct. The gross earnings per ton of coal burned by the same stations varied from $12.10 to $35.50, showing some remarkable contrasts scarcely to be expected in so small an area as that occupied by the Bay State. Even the larger stations were notable for the variation in operating results obtained. Such differences as these, and Massachusetts is but an example of what prevails in many other sections, point to the need of a more thorough study of electric lighting economics, and the consulting engineer is certainly the exact man to meet the situation, if anyone can meet it.

The manager of a small central station seldom has the time to make the specialized comparisons of data which determine the final engineering and commercial efficiency of his plant as compared with another affected by somewhat similar conditions. Between keeping his customers satisfied and trying to show a dividend balance through careful operation and close attention to the securing of new business the manager of the small plant has little opportunity to go afield for the material which is so readily acquired by the consulting engineer paying special attention to comparative power station economy. Further than this, a disinterested and unbiased expert examination is almost certain to bring out a number of valuable operating criticisms and suggestions which the daily routine of central station management often fails to disclose. Something more than ordinary operating activity is needed properly to co-ordinate the discrepancies between plants which are doing the same general kind of work in the same general class of territory, but which for one reason or another, do not show similar results. The mere existence of a town boundary line is scarcely a sufficient reason for a jump in the ratio of operating expenses to gross earnings of from 50 to 85 per cent.

Doubtless many small central stations have in the past hesitated to pay the cost of expert advice through lack of ready means available for that purpose. A little consideration, however, of what has been done in larger work will often show that the lasting benefits of expert engineering far exceed the specialist's fee. Of course engineers are not lacking, as there also are bankers, to whom a small proposition does not appeal, but it is a great mistake to decide that expert advice cannot be had in a plant simply because it is a small one, and at reasonable price. And lastly, there are unworked possibilities in the community of interest idea, where two or more small plants jointly employ a consulting expert to analyze their economic production, to their mutual benefit and lessened individual expense. From the standpoint of the engineer the small plant is seldom worth neglecting as a client, and from the standpoint of the central station a little sound advice from an experienced analyst is nearly always worth a great deal more than it costs.

Motor-Operated Valves.

The recent accidents to large water mains in New York and Boston, resulting in the former case in the paralysis of subway traffic for many hours, and in the latter, in great inconvenience in the Washington Street Tunnel construction, indicate strongly the importance of equipping trunk line underground valves with electrical means of closing in preference to the slow and laborious hand operation at present so largely employed. Considering the costliness of such accidents in all their bearing upon complex urban life, it is singular that municipalities have as yet taken so little advantage of the experience gained in the use of motor-operated valves under all sorts of trying conditions by those who have had

the foresight to adopt them. The matter of first cost is not to be weighed seriously against the loss which often follows the bursting of a single 36-inch main, and the operating expenses are certainly insignificant when the saving in labor is duly appreciated.

Small motors are now on the market capable of performing any task in the way of valve closing, which either ordinary or emergency service demands. In the power station the ability to close important steam valves quickly from a distance is of great value in cases where steam pipes have burst, for many times the discharge of steam is such that no employee can reach the point where the valve is located. Although direct-current motor-operated valves are open to some objection for service around steam piping, it ought to be possible to apply the induction motor to such work with success, in view of the severe service which such motors are undergoing in all sorts of damp, dirty, hot and fume-sodden places. In fact the induction motor would also seem to be the ideal machine for the operation of water works and gas main valves underground, especially when the soil is frozen. Pipe galleries may isolate the effects of a break, but the real point is to stop the flow as soon as possible after rupture occurs, and for saving valuable minutes and in assisting in the speedy location of breaks in such cases the motor-driven valve deserves much more extended use than it has received.

Window Illumination.

Perhaps there is no branch of artificial lighting which offers a better field for the practice of original ideas than does the illumination of show windows. So widely do the conditions vary as to the kind and quantity of merchandise displayed; so different are the exhibit spaces, shapes and surroundings, and so diverse the color schemes found in shop windows, that it is really a specialist's task properly to design a modern window display, including that vital means to an end—the lighting arrangement.

The principal technical requirements of window lighting are simple in themselves. All that is needed is that the goods displayed shall stand out boldly against a suitable background; that the illumination shall be brilliant enough to attract the observer's attention to the goods, and even enough to enable the spectator to see all parts of the merchandise exposed, with clearness and without too much shadow. In common with all other forms of lighting except sign work, the equipment for producing window illumination must be so disposed as to attract no attention to itself, if the maximum effect of the displayed wares is to be secured. This principle is so often violated that central station men should lend their influence to the better disposition of equipment, which, otherwise in the hands of inexperienced customers, is likely to be grossly misapplied.

It is scarcely necessary to point out to technical men the superiority of electricity over all other illuminants for window work, but there is still great need for a more general appreciation on the part of the public of the advantages with which it is peculiarly endowed. Here again is a plain duty for the central station man, and one which he is usually not slow to improve. It is an undisputed fact that the cleanest and most artistic window display work now being done is accomplished by electricity alone. Look at any shop window lighted by Welsbach gas mantles after the first few weeks of glaring splendor have passed. A comparison of the ghastly illumination of such an installation with the even, brilliant, soft light of a well-designed electrically equipped window, emphasizing the differences to one's customers, is usually effective. There are object lessons of this kind in almost every city and town of commercial importance.

Considering the injurious effects of the gas-vitiated atmosphere upon delicate fabrics, bric-a-brac, polished silverware, books and other expensive merchandise, it is difficult to see why any other illuminant except electricity should be selected. It is to the central station's advantage to make a rate for window lighting during the evening hours that shall be almost irresistible to the progressive merchant, for, as in the case of the illuminated sign, discussed briefly last month, the business occurs at a time when the plant needs greatly to increase its output, or rather, to keep up its production. Towns which enjoy attractive window lighting on the principal streets during the evening are certain to benefit indirectly through enhanced reputations as live centres of population, and although the larger cities do not need this sort of advertising particularly, the result of a heavy window load is certain to be profitable to both the community and the merchants, while the central station reaps the benefit of the progressive policy.

A point often overlooked in electric window lighting is that more can be done at small expense than would appear at first sight. The use of mirrors and reflectors is well worth considering in most average cases; it is not necessary to install a great number of high powered lamps as a rule. A recently equipped jewelry store window containing twenty-one square feet of display space was found to contain forty-two 16-c.p. and thirty 8-c.p. lamps, or over 43 candle-power per square foot. The results were naturally most brilliant, but there is no question that the use of several lamps of the Nernst or Meridian types would have given quite as good or better service and at far less cost. There is always a point where the illumination ceases to be an auxiliary to the display of goods, and becomes inherently of chief interest. Such a point had long been passed in the case just cited.

No window installation is complete without attention having been paid to the fire risk of the wiring and arrangement of equipment. Care in the use of lamp bulbs around inflammable material is one of the first requisites; the very flexibility of electric lighting opens the door to possible misuse and danger.

Electricity in the Drug Store.

An attractive field for the sale of central station current, and one which has by no means been over-exploited as yet, is found in the retail drug store. Of course, the use of electricity for lighting displays, signs and general illumination has found favor in the domain of the druggist as well as elsewhere, but comparatively little, apparently, has been done thus far to push the small motor into useful places in the apothecary's shop.

Each summer, however, the uses of the small motor grow wider, and at the present time many druggists' establishments are equipped with electric fans, particularly in the vicinity of soda fountains, while others are adopting motors to operate milk shake machines, to drive the cream freezers, ice crushers, small lathes, special grinders, moving advertisements in the windows, and the like. A little study of the possibilities in this direction by central station men is likely to be fertile in results, for the manufacturers of small motors stand ready to produce a practical design to drive any sort of commercial machinery that the druggist employs. In these days of close profits, new business, even in the smaller fields, is worth investigation, for in the aggregate it is likely to be highly profitable.

HOW TO MAKE AN ELECTRIC BUCKBOARD.

BY J. C. BROCKSMITH.

The Motor.

In last month's article complete information and drawings were given for the running gear. It is the purpose of the present article to describe the motor with which to drive the buckboard.

The motor is a four-pole machine having a circular yoke of soft cast steel in one piece with the poles. It is provided with cover plates of aluminum alloy, which completely encase the working parts. All the motor bearings are of the steel ball type in order to reduce friction and wear to a minimum. The winding is of the series type for 80 volts and the speed under full load and voltage is 2800 to 3000 r.p.m. The maximum brake horse-power is about 1½.

Fig. 10 is a vertical section of the complete motor which shows the working parts of the motor in their proper position. This view brings out the construction of the bearings, commutator, brush holders and also the reduction gearing upon the sprocket shaft. It will be noted that the field cores are set somewhat off the center of the yoke, which allows for the space taken up by the commutator, and permits of the use of cover plates, which are alike, and therefore require only one pattern. The large central opening in the shell is bored and threaded to receive caps which when screwed on completely encase the motor. By removing the cap at the commutator end the brushes and commutator may be inspected without disturbing any of the other parts. The size of brushes used is ⅜ x ⅝ x 1 inch plumbago.

The counter-shaft, which carries a sprocket on one end for the chain drive, passes through the motor between the two lower field coils and has a 94-tooth, 20-pitch B. & S. gear keyed on the opposite end; this meshes with a 15-tooth, 20-pitch pinion made of tool steel and hardened in oil. This makes the distance between centers 2.725 inches.

Fig. 11 is an end elevation of the field frame and armature core. The bore is 3 9/16 inches, and the core is 3½ inches in diameter and has 18 round slots 13/32 inches in diameter. These discs are a standard size in use by one of the leading electrical manufacturing concerns and can be purchased from stock, or they can be produced by the builder by the process of drilling the slots already described in connection with previous small motor designs.

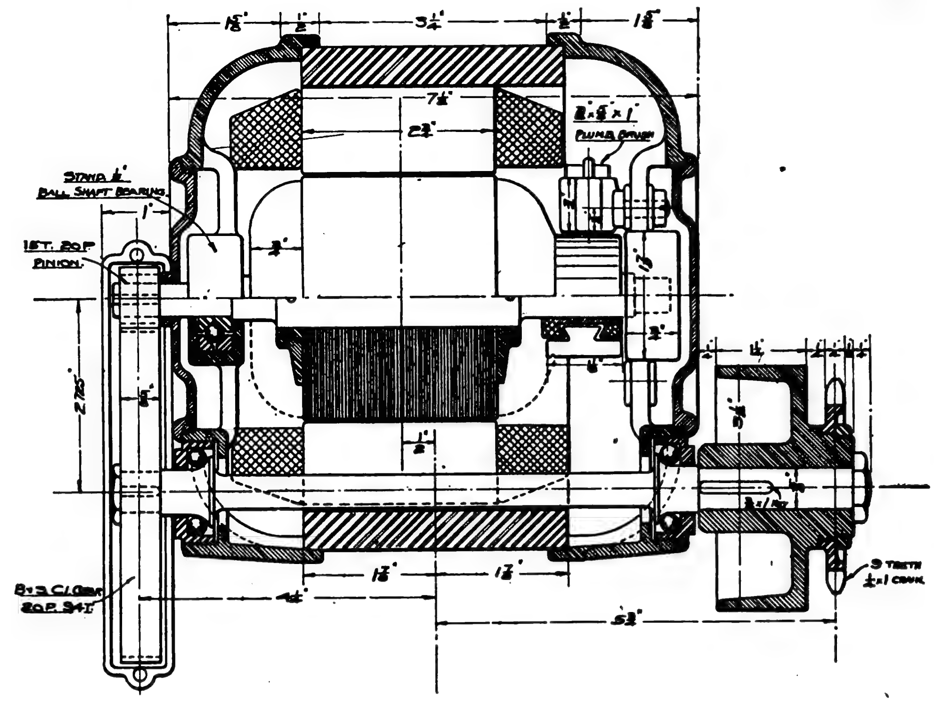

FIG. 10.—VERTICAL SECTION OF COMPLETE MOTOR.

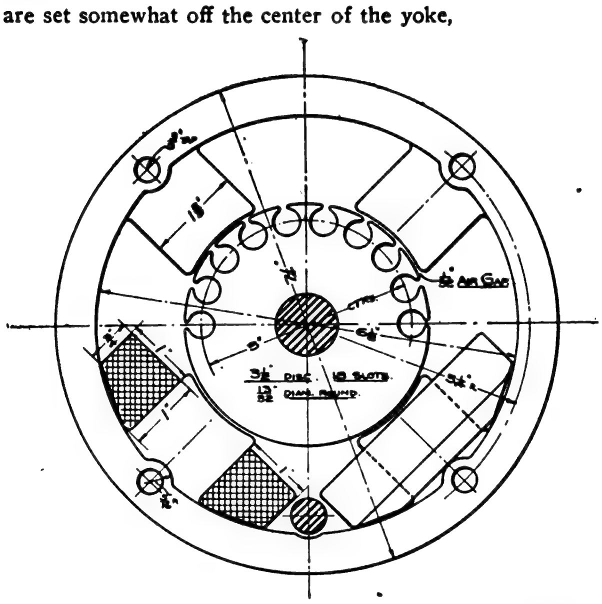

FIG. 11.—END ELEVATION OF FIELD AND ARMATURE.

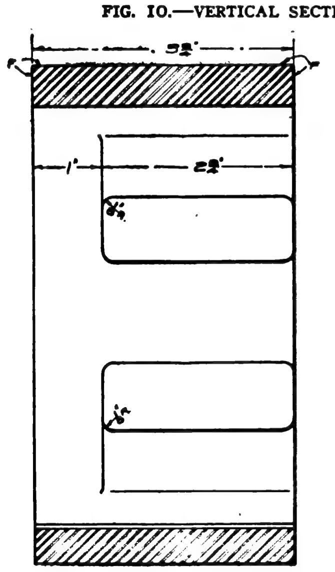

FIG. 12.—SECTION OF FIELD FRAME.

Fig. 12 is a section of the field casting, which shows the width of the yoke and the offset of the poles. No pole shoes are used, the field coils being simply slipped over the poles and retained in position by means of hard wood wedges driven in between the core and the coil. At four points around the circular yoke, holes are drilled and tapped for ⅜ x 2-inch hexagonal cap screws, which serve to fasten the bearing shells to the field frame. In finishing the field casting the polar space is bored out and the ends of the circular yoke faced off. The outer surface of the yoke also should be trued for a distance of about ¼ inch from each end, so as to afford a true seat for the bearing caps, which must be bored on their inner surfaces to fit the finished portions of the yoke.

Fig. 13 shows the details of the cover plate both in elevation and section. It consists of a curved shell, which covers the field coils, and in the center of which is the case for containing the ball armature bearings. This is supported from the wall of the shell by means of four radial arms,

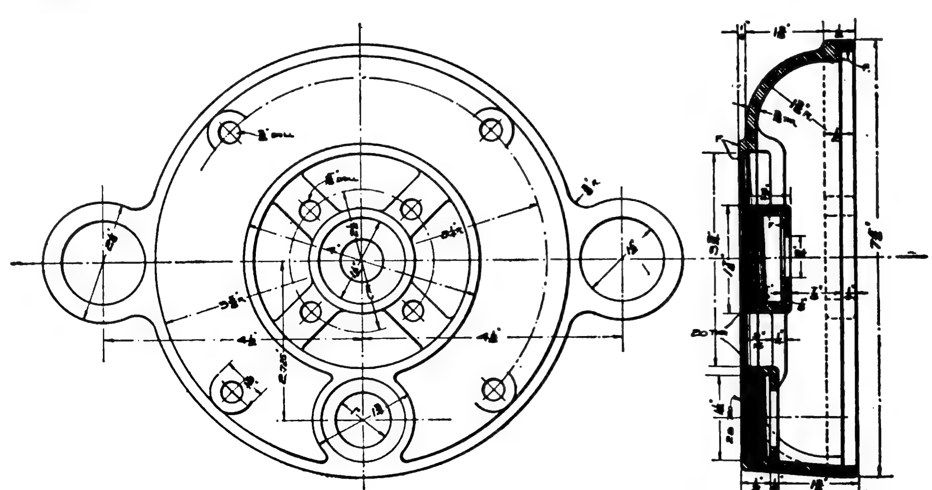

FIG. 13.—END VIEW AND SECTION OF COVER PLATE.

which also serve to support the brush holders, for which purpose they are drilled with 5/16-inch holes.

A circular boss is located 2.725 inches below the center of the armature shaft,

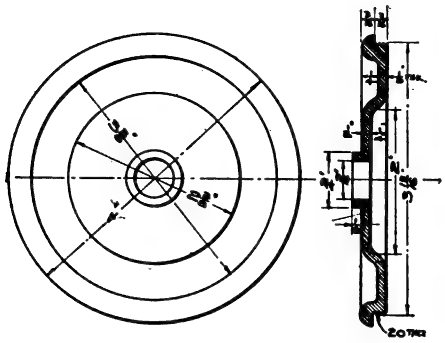

FIG. 14.—DETAIL OF COVER PLATE CAP.

and is bored and threaded for the tool-steel ball cups forming the counter-shaft bearings. This center to center distance must be exact for upon this depends the proper meshing of the gears. It is better to err on the side of having it a little full rather than scant. The case for containing the armature ball bearings is to be bored and threaded to suit the steel races, the bore being, of course, exactly concentric with the finished portion on the inner periphery of the shell which fits the field frame. The armature bearings are of the "grooved shaft ball bearing" type, which can be obtained ready made in standard sizes, of which this is one. They consist of three hardened and ground tool-steel races and a set of 12¼-inch balls. One of these races is in the form of a spool which fits the shaft snugly, while the other two fit the case, one being threaded for the purpose of adjusting the bearing.

Fig. 14 is a detail of the cap for closing the central openings in the cover plate. Two such caps are necessary, one having a hole in the center for the armature shaft to pass through, while the one at the commutator end is left blank. Both these caps, as well as the cover plates proper, are intended to be cast of aluminum alloy containing 25 or 30 per cent of zinc.

Fig. 15 shows the details of the armature and counter-shafts. The armature shaft can be conveniently made from a piece of ⅞-inch, cold-rolled steel; if care is taken in centering the piece, the middle portion will not require turning. The shaft is drilled for pins to be driven in after the core discs have been slipped on and the cast end discs have been pressed into place.

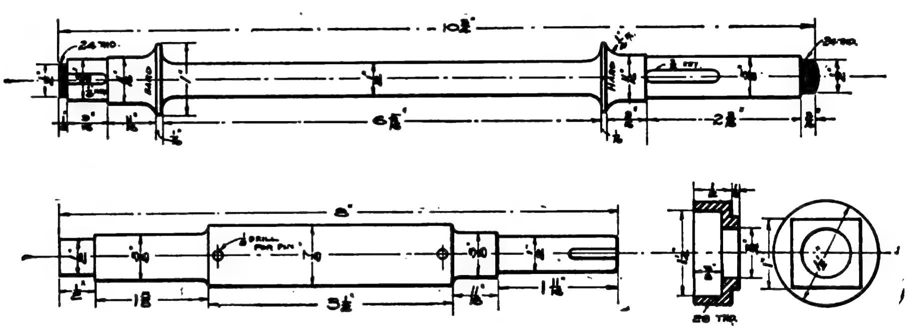

FIG. 15.—DETAILS OF ARMATURE AND COUNTER-SHAFTS.

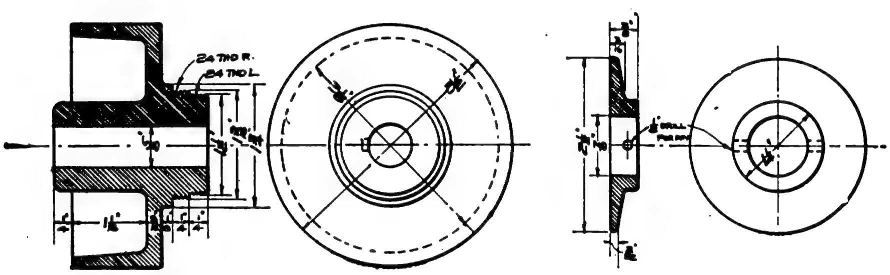

FIG. 17.—DETAILS OF BRAKE DRUM AND ARMATURE END DISC.

The counter-shaft is intended to be turned from a bar of 1-inch annealed tool steel, after which the cones are hardened. An easier but not so substantial construction is to use ½-inch cold-rolled steel with cones of tool steel pressed on and pinned in place.

Fig. 16 contains the details of the commutator and brush holders. The commutator can be most conveniently made from a phosphorized copper casting turned to the size shown and then sawed into 18 equal segments by means of a No. 23 screw-slotting cutter mounted on a mandril in the lathe. The segments thus obtained are built up with mica insulation equal in thickness to that of the cutter, and are clamped in a brass sleeve and nut having flanges undercut at a 60-inch angle. The brush holders are of cast brass; the slot for the brush can be cored very nearly to size and filed to a smooth finish. The brush should slide freely in its holder, but without play. The brushes should be of plumbago ⅜ x ⅝ x 1 inch, copper-plated, and each should be "pig-tailed" to its holder with some flexible bare copper wire. The springs are contained in a lug cast on the brush holder and are made up of No. 19 "Helmet" bronze wire, which is coiled on a mandril so as to be about 5/16 inch outside diameter. The insulation for the brush holders consists of fibre washers and some small fibre bushings, the dimensions of which are indicated in the drawing.

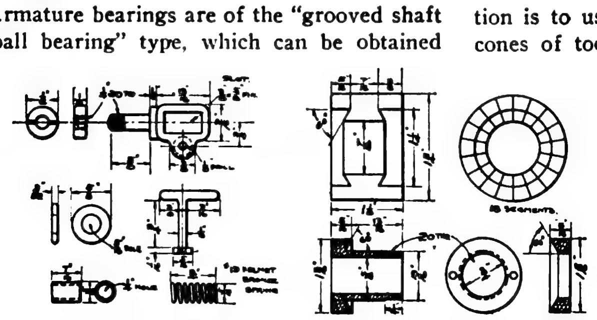

FIG. 16.—DETAILS OF COMMUTATOR AND BRUSH HOLDERS.

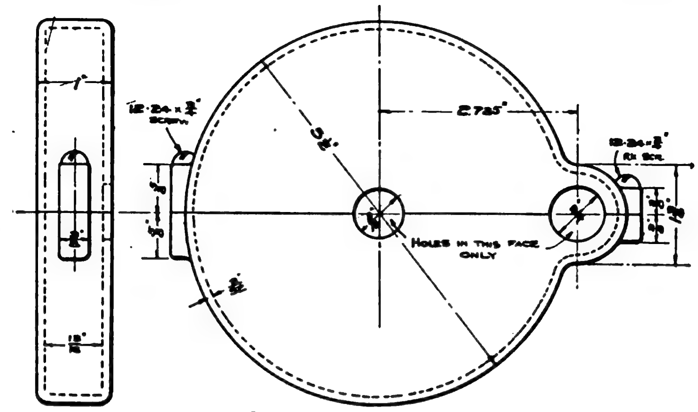

FIG. 18.—DETAILS OF GEAR CASE.

Fig. 17 shows the details of the brake drum and the end discs for the core. Both these parts can be cast of alzinc and are preferably finished all over.

Fig. 18 is a detail of the case for enclosing the motor reducing gears; this can be cast from alzinc and finished bright to give a good appearance. A half pattern will do, of course, as both halves of the case are alike. This case is intended to be partially filled with a heavy oil to reduce noise and wear of the gears to a minimum. The addition of some graphite in the oil also helps.

Fig. 19 represents graphically some results of a brake test of the complete motor, giving the curves of speed, torque and efficiency, as referred to amperes input. It will be noted that the efficiency is a maximum, 79 per cent, at 9 amperes input, this being almost exactly the usual full-speed current consumption when the motor is driving the buckboard. What the torque, speed and efficiency will be at any other current can be obtained directly from the curves, which makes it easy, by taking readings of current, to arrive at the resistance of various

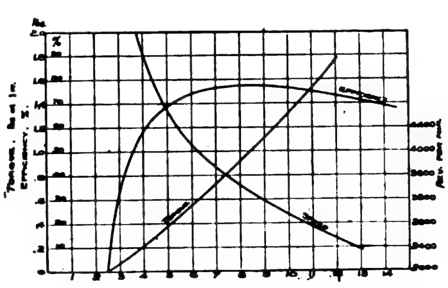

FIG. 19.—MOTOR CURVES.

kinds of road surfaces and on hills. The speed of the motor at 40 volts, the second controller notch, would, of course, be half the value shown on the curve for the same current input. With a set of curves of this kind obtained from brake test and knowing the total ratio of reduction between armature shaft and rear axle it becomes unnecessary to take any speed readings on the road, as the whole performance can be deduced from simply the voltage and current readings.

The following is a brief summary of the principal design data of the motor and the winding:

SUMMARY OF DATA FOR MOTOR.

¾ kw, 80 volts, 9-10 amperes; estimated efficiency, 75 per cent. Steel frame, 4 poles, W. E. punchings in arm; armature, 3½ inches diameter, 2¾ inches long; 18 slots 13/32 inch diameter round, ⅜ inch net diameter after insulating; No. 19 wire, d.c.c.; 46 wires per slot; 18 coils, 23 turns per coil, No. 19 d.c.c. Parallel lap winding, connections straight out to adjacent commutator segment. Field coils 94 turns per coil; No. 12 d.c.c. wire. Coils must not exceed 1 inch in depth. Weight of armature wire, 2 pounds, No. 19 d.c.c.; weight of field wire, 8 pounds, No. 12 d.c.c.

MODERN STEAM TRAPS.

BY W. T. EDWARDS.

Water of condensation which usually collects in a steam pipe system is invariably removed by drip pipes which feed into what is known as a steam trap. This is a device consisting of a reservoir wherein the water of condensation collects and is forced out into a tank, drain reservoir or sewer by the pressure of steam in the drip pipe system, the controlling valve being actuated by the water in the trap.

Steam traps should be so placed that the water gravities into them. This water may be discharged to a height or head equivalent in pressure to somewhat less than that in the pipes drained. Such traps are known as tank or separating traps.

Return traps which return the condensation to the boiler are placed in a convenient location about three feet above the water line in the boiler, the condensation being forced into the trap by the pressure in the drip pipes. When the trap discharges communication is had between it and the boiler. The entering steam from the boiler equalizes the pressure and the water gravitates into the boiler.

Steam traps are often condemned, not because of faulty design, but because they are operated under conditions for which they were never designed, and sometimes because of improper connections or arrangement of piping, valves, etc. It is the purpose of the present article, therefore, to show modern types of steam traps, their method of operation, and in some cases the manner of piping that is recommended to obtain the best results.

The A. A. Griffing Company, Jersey City, N. J., manufactures a line of return and separating traps, which is known as the "Bundy." These are made in four series, comprising 29 sizes, each series being designed to operate under certain definite

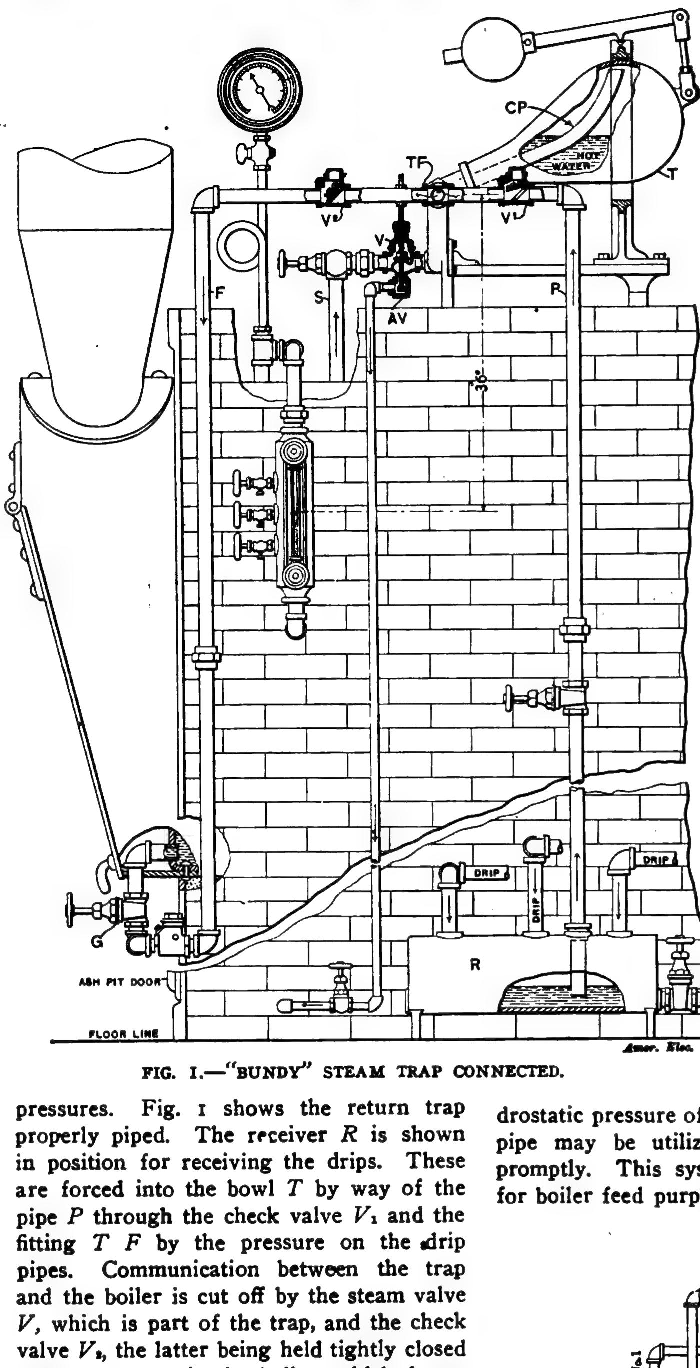

FIG. 1.—"BUNDY" STEAM TRAP CONNECTED.

pressures. Fig. 1 shows the return trap properly piped. The receiver R is shown in position for receiving the drips. These are forced into the bowl T by way of the pipe P through the check valve V_1 and the fitting T F by the pressure on the drip pipes. Communication between the trap and the boiler is cut off by the steam valve V, which is part of the trap, and the check valve V_2, the latter being held tightly closed by the pressure in the boiler, which forces a column of water through the pipe F. When the bowl T is filled with water, the combined weight overbalances the weight on the ball of the lever and causes the bowl to drop to the discharging position, which opens the valve V. Live steam from the boiler is then admitted into the trap through the pipe S, thus equalizing the pressure on both sides of the entrapped water, which then gravitates into the boiler. While the trap is discharging the check valve V_1 is held closed against the drips by the pressure of steam in the boiler and the check valve V_2 is open, permitting the water to pass through the pipe F to the boiler. When the trap is empty the bowl returns to its original position. The drip water enters and is discharged from the bowl through one trunnion, while live steam from the boiler enters through the other trunnion and the pipe C P. Should any air be trapped it is discharged through this pipe and passes through the air vent valve A V into the ash pit. This valve is fixed on the same stem as the steam valve and is open while the trap is filling and closed while it is discharging.

Should the pressure upon the steam system to be drained not be sufficient to force the drips to the bowl of the trap located above the boiler a system called the duplex is used. This comprises two return traps of the same size, one elevating the water into the other, which is placed in its proper position above the boiler. Fig. 2 shows this arrangement. The lower trap, 1, receives the water and communicates directly with trap 2, which is supplied with live steam as indicated. It has been found advisable to locate in the discharge pipe line from trap 1 a weighted check valve or spring relief valve, set to open at a pressure less than that supplied to the trap. This acts as a stop in the pipe whereby the full hydrostatic pressure of the water in the supply pipe may be utilized to fill trap No. 2 promptly. This system is sometimes used for boiler feed purposes.

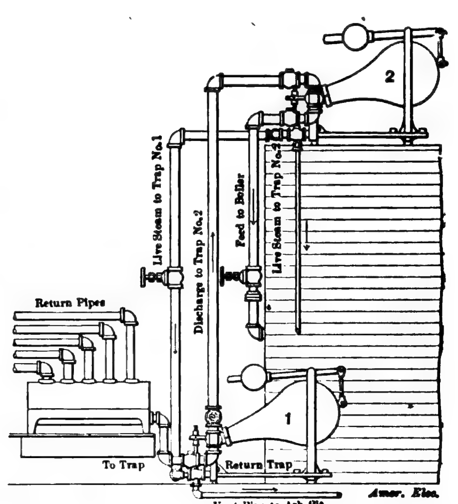

FIG. 2.—DUPLEX SYSTEM OF "BUNDY" TRAPS.

A sectional view of the 100 and 200 series of "Bundy" return trap is illustrated by Fig. 3. A cast iron receiving bowl is supported on a yoke and frame by two trunnions. The water enters the feed trunnion

D as shown in the sectional view of the yoke and passes into the bowl. The weight of this when full overbalances the weight of the ball *E* on the horizontal lever *F*.

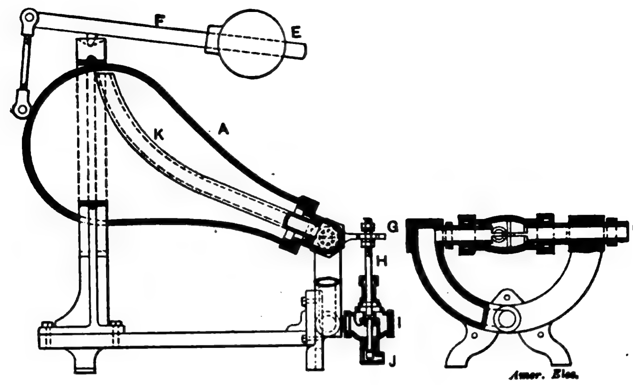

FIG. 3.—SECTIONAL VIEW OF "BUNDY" RETURN TRAP.

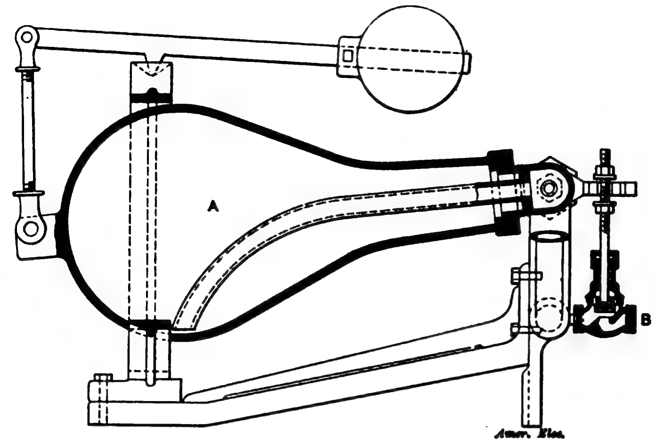

FIG. 4.—SECTIONAL VIEW OF "BUNDY" SEPARATING TRAP.

The projecting ring *G* pulls up the valve stem *H* when the bowl drops, thus opening the valve *I* and admitting live steam.

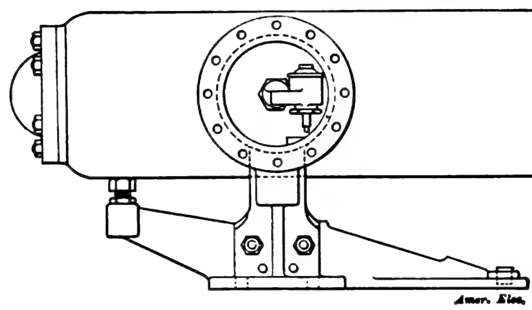

FIG. 5.—"BONER" STEAM TRAP.

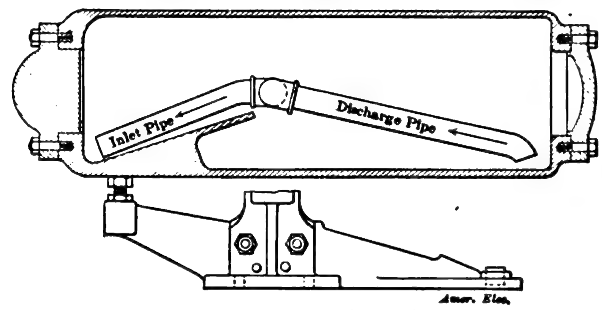

FIG. 6.—SECTIONAL VIEW OF "BONER" STEAM TRAP.

The pressure on the trap and boiler now being equal, the water is free to flow into

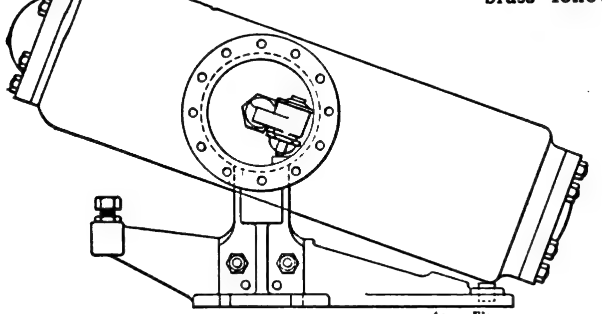

FIG. 7.—"BONER" STEAM TRAP.

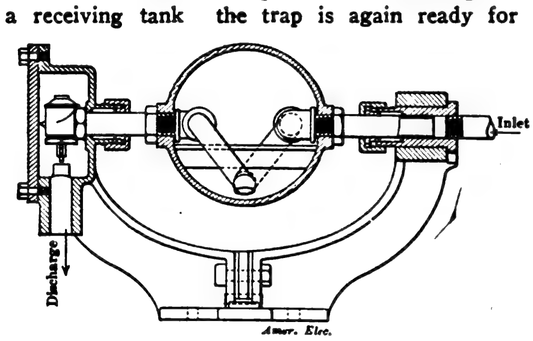

FIG. 8.—TRANSVERSE SECTION OF "BONER" STEAM TRAP.

the boiler. When the bowl is empty the weight on the lever returns it to its normal position, closing the steam valves, and at the same time opening the air valve *J* in order to permit any steam and air which may remain to escape. The steam enters the bowl through the curved pipe *K* and is discharged upon the surface of the water.

Fig. 4 shows a sectional view of a separating trap of the 50 and 75 series. This construction is practically the same as that of the 100 and 200 series; but the method of operation is somewhat different. The water enters the feed trunnion which occupies the same position as that on the return trap. When the bowl drops the discharge valve *B* is opened, as shown in this sketch. The pressure on the drips forces the water out through this valve. Before the bowl is entirely empty, and while there is enough water left to seal the end of the pipe *A*, the bowl tilts back into the filling position and effectually closes the discharge valve. This style of valve will raise water to a height equal to the pressure available, or it will discharge against any pressure which is less than the pressure on the trap, allowing a reasonable amount for friction losses. The traps are made of cast iron and the trunnion and boxes are fitted with brass followers. When a receiving tank is used to collect the drips, it is advisable to place a swing check valve in each line near the tank in order to prevent any possible short circuiting. It is also advisable to place a shut-off valve in each line near the appliance dripped.

Another trap in which the discharge valve is operated by the movement of the collecting tank is the "Boner," manufactured by James Bonar & Co., Incorporated, of Pittsburg, Pa. This trap is shown by Fig. 5. It consists mainly of a cylindrical receiving tank supported on trunnions placed nearer one end than the other. The shorter end is made heavier than the longer end in order to keep the tank in a horizontal position. When the tank is full the long end tilts, opens the discharge valve and permits the water to be forced out. The trunnions receive and discharge the drips, as shown in the sectional views. The trunnions are part of the cylinder and move with it. Fastened to the end of the outlet trunnion is the discharge valve, which is of the ball type; in the bottom of the valve is a loose pin, which comes in contact with a projection in the valve casing and lifts the ball from its seat while the tank is discharging. When the tank assumes its normal position the discharge valve closes and the trap is again ready for use. Fig. 6 shows the tank in the receiving position, Fig. 7 shows it in the discharging position

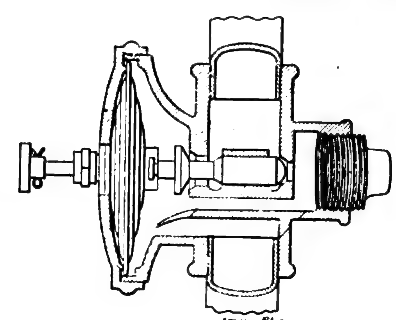

FIG. 9.—"DUNHAM" STEAM TRAP.

and Fig. 8 is a transverse section showing the inlet and discharge pipes connected with the trunnions and also the ball discharge valve. The trap is very simple and effective in operation.

Fig. 9 shows a sectional view of the "Dunham" special steam trap, manufactured

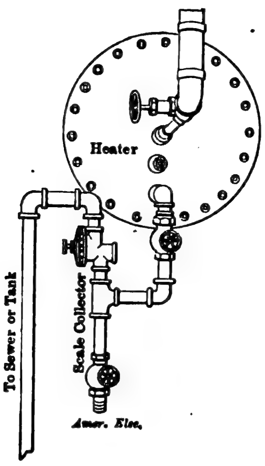

FIG. 10.—"DUNHAM" TRAP CONNECTED.

by the C. A. Dunham Company, of Marshalltown, Iowa. The principle of operation is quite different from that of the regu-

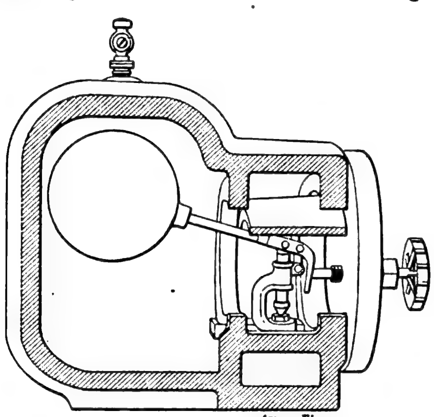

FIG. 11.—"COOKSON" STEAM TRAP.

lar type of trap. Instead of making use of floats, levers, pots or buckets to operate the valve, use is made of a chamber formed

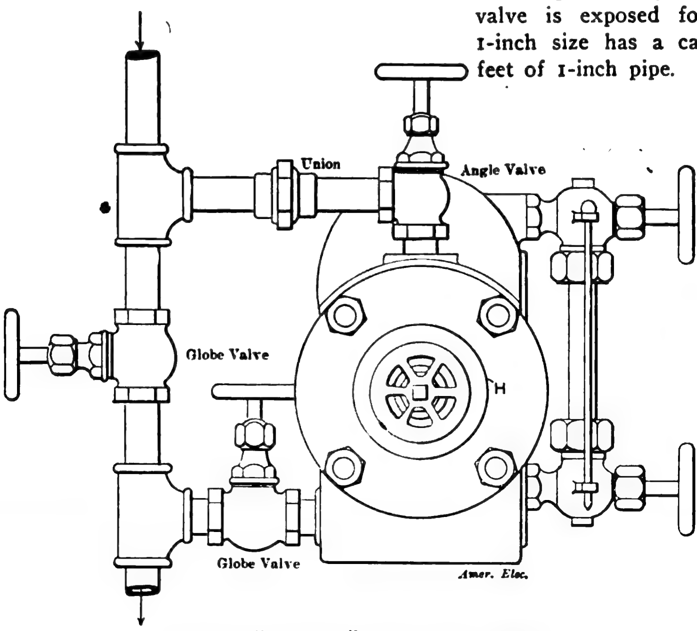

FIG. 12.—"COOKSON" TRAP CONNECTED.

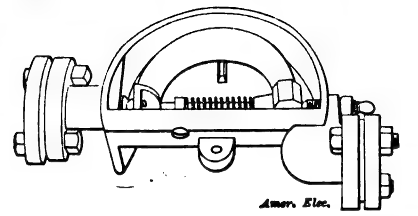
by two discs of sheet bronze which contains three fluids of different degrees of volatility. These fluids flash into vapor as the temperature rises, thereby developing a pressure and closing the valve. They condense when the temperature is lowered, forming a vacuum, and the pressure upon the outside of the walls of the chamber forces them together and opens the valves From this it is evident that the valve is governed by the amount of condensation occurring in the system drained. The trap may be adjusted to discharge continuously. It is made of phosphor bronze throughout, and is peculiarly adapted to steam heating systems. As it remains open at a normal



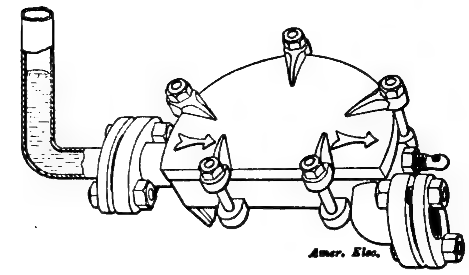


FIG. 13.—"MARCK" STEAM TRAP.—FIG. 15.

low temperature it allows air or water which may be in the heating system to escape, the trap closing when steam reaches it. It possesses an advantage in size and is designed to work from vacuum up to 125 lbs., adjusting itself to any pressure

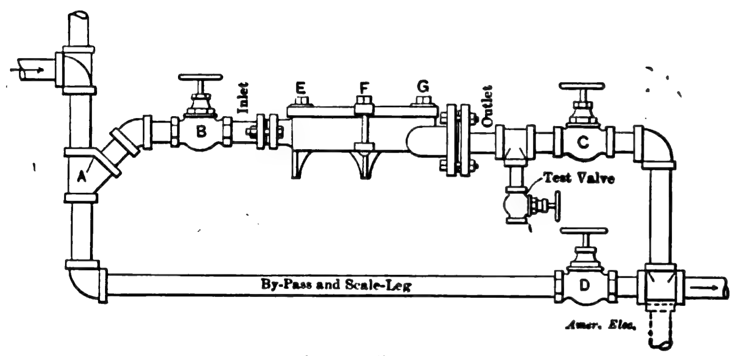

FIG. 14.—"MARCK" TRAP CONNECTED.

within these limits. The valve opening is large and the valve is double seated, as shown in Fig. 9. The trap body, disc, valve, steam cap and plug constitute all of its parts. By removing the cap the valve is exposed for any repairs. The 1-inch size has a capacity of 1000 linear feet of 1-inch pipe. There being no reservoir in this trap to catch and hold scale or foreign matter, provision must be made to prevent its entrance into the trap. This may be obtained by a system of piping like that shown by Fig. 10.

The Cookson Steam Specialty Company, of Cincinnati, Ohio, manufacture the "Cookson" steam trap. This is of neat design and large capacity and is built to withstand all ordinary working pressures. But one type of trap is manufactured and this is adapted to either high or low pressure by simply changing the valve and seat. All parts are made from templates and are interchangeable. By turning a hand wheel operating a threaded spindle acting against the valve the latter may be opened to its fullest extent, as indicated by Fig. 11, for the purpose of blowing out any foreign matter that may have lodged upon the valve seat. By backing out the spindle the valve is allowed to re-seat itself. Fig. 12 shows the trap piped and by-passed as recommended to get the best results. *H* is the hand wheel for operating the valve. Three valves are used, the arrows indicating the direction of flow of the drips.

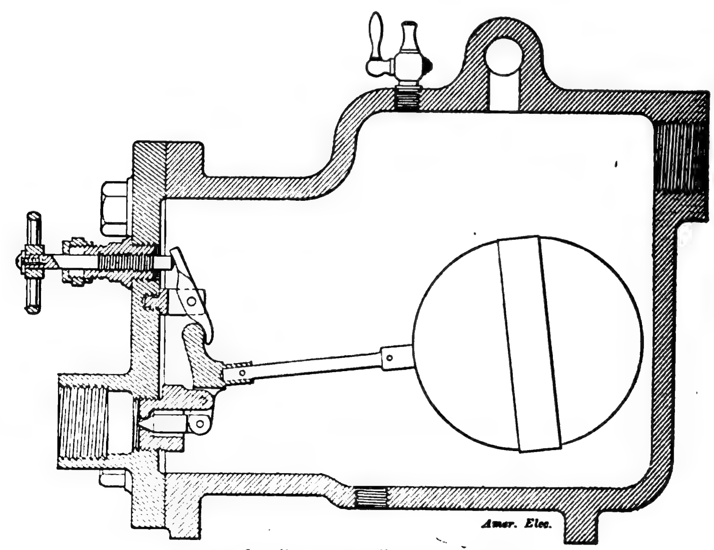

FIG. 16.—"RELIANCE" STEAM TRAP.

The "Marck" steam trap, with its cover removed, is shown by Fig. 13. This trap has but one movable part, consisting of a hollow tube bent to the shape of a crescent. This tube is made of strong selected metal,

and is filled with liquid which gasifies at 212° Fahr. When this liquid becomes gaseous, the expansive force has a tendency to straighten the tube. This causes the valve to press against the valve seat and close

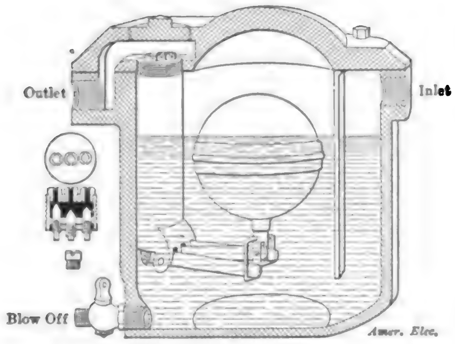

FIG. 17.—WRIGHT "EMERGENCY" STEAM TRAP.

the trap. When the temperature falls below 212° Fahr. liquefaction takes place and the tube assumes its normal position, drawing the valve away from its seat and opening the trap. The trap is automatic, depending for its effective working on the tube in which the fluid is contained. It is simply an automatic valve or separating trap, whch always opens below 212° Fahr. and closes above that temperature. It will operate at any pressure below 200 lbs. to the square inch, and since it is not provided with a receptacle for the collection of sediment, scale, etc., it is advisable to construct a trap or scale leg by extending the inlet pipe as indicated by Fig. 14. This illustration also shows the trap by-passed. Fig. 15 shows another view of the "Marck" trap, which is manufactured by E. F. Houghton & Company, Philadelphia, Pa.

Another separating trap, the valve of which is operated by a float, is shown in section by Fig. 16. This is called the "Reliance" trap, and is manufactured by the Reliance Gauge Column Company of Cleveland, Ohio. The working of the trap is so clearly indicated in the engraving that no description is necessary. The traps are made in six sizes, from ½-in. to 2-in. connection inclusive, the smallest draining 1000 ft. and the

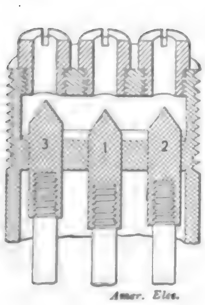

FIG. 18.—WRIGHT VALVES AND SEATS.

FIG. 20.—"GOLDEN" HIGH-PRESSURE TILTING STEAM TRAP.

largest 16,000 ft. of one-inch pipe. When the pressure under which the trap is to work is less than 30 lbs., a large valve outlet is provided.

The traps already described are provided with single valves, but the one shown in Fig. 17 is provided with three. This illustration shows a sectional view of the Wright "Emergency" trap, manufactured by the Wright Mfg. Company of Detroit, Mich. This trap operates successfully on all pressures from 20 to 200 lbs. per square inch. A low pressure trap called the "Victor" is made by the same company for pressures up to 20 lbs.

The "Emergency" trap consists of a cast iron chamber wherein the water collects. Within this chamber is a specially designed and reinforced copper ball float, which actuates the three valves. The valves are arranged so that a normal quantity of water is discharged through one valve. Should the quantity of water be abnormal the float is raised high enough to open the second

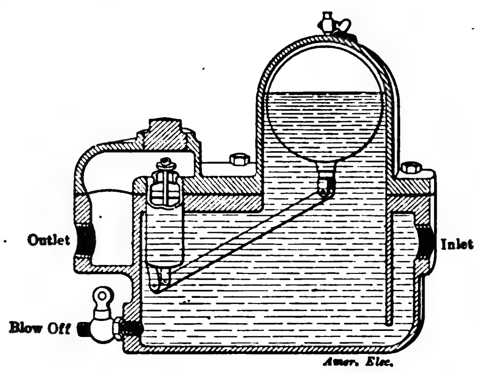

FIG. 19.—"VICTOR" STEAM TRAP.

valve, and in cases of emergency the third valve is also opened, the float then being in its highest position. When the three valves are open they provide for the full capacity of the inlet pipe. Ordinarily one valve is sufficient to do the work. The valves and seats are made of steel jet metal and are so arranged as to be easily renewed or repaired without removing the cover, a plug being provided for that purpose. The valves are held in alignment by a bar placed diametrically across the tube, which also serves to center the valves into the seats. An enlarged view of this arrangement is shown by Fig. 18.

The "Victor" low pressure trap is similar in construction and operation to the "Emergency" trap with the exception that it has but one valve. This, however, is large enough to enable the trap to handle large quantities of condensation. Both types of trap are provided with gauge glasses and blow-off cocks and the "Victor" is provided in addition with an automatic air valve. This trap is shown in section by Fig. 19.

Fig. 20 shows the Golden high-pressure, automatic tilting steam trap made by the Golden-Anderson Valve Specialty Company of Pittsburg, Pa. The trap is shown in normal position ready to receive the condensation. When sufficient water is trapped to overcome the weight of the ball on the lever, the trap drops, thereby opening the steam valve and the water is forced out. The trap then resumes its normal position under the action of the weighted lever. The trap is well made, all working parts being of bronze and removable.

The American Electric & Controller Company of New York City is the manufacturer of the "Thoen" steam trap, shown in section by Fig. 21. The operating element of the trap consists of a bucket supported at its upper end between the forked ends of a counterweighted lever. The counterweight exactly balances the weight of the bucket when it is empty. That is to say, the moments of all the weights on the right side of the pivot are equal to those on the left

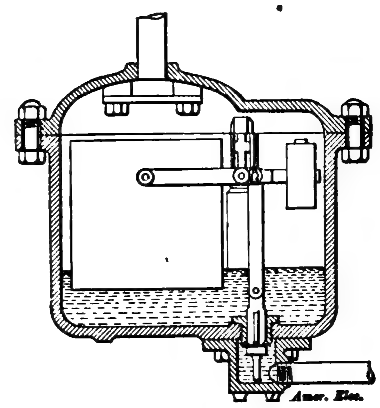

FIG. 21.—"THOEN" STEAM TRAP.

side, so that when the trap is empty the moving parts are in equilibrium. When the trap begins to fill the preponderance of weight on this side of the lever support keeps the outlet valve tightly closed. When the bucket is full and overflows, the body of the trap begins to fill up and the buoyancy of the bucket increases until such a point is reached that the moments on each side of the fulcrum are again nearly equal, when the unbalanced steam pressure on the upper side of the valve seat causes it to open. Discharge then, of course, takes place until the level of the water outside the bucket lowers to such a point that the weight of the water in the bucket again causes the outlet valve to close. Since the bucket is full of water at all times when the trap is in operation, and from the nature of its operation, the discharge of liquid is seen to be but a small amount at a time, and the action of the trap very sensitive. The outlet valve is also submerged at all times, and this, of course, prevents the escape of steam. A feature which is not perhaps noticeable is that the outlet hood

or chamber is attached to the main body by four bolts placed exactly 90 degrees apart, so that the outlet pipe may be turned in any one of these four positions.

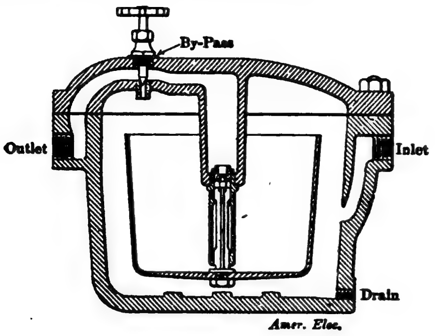

FIG. 22.—"CRANE" STEAM TRAP.

The Crane Company of Chicago manufactures a steam separating trap of the bucket type, as shown by Fig. 22. In operation the trap does not differ from the many

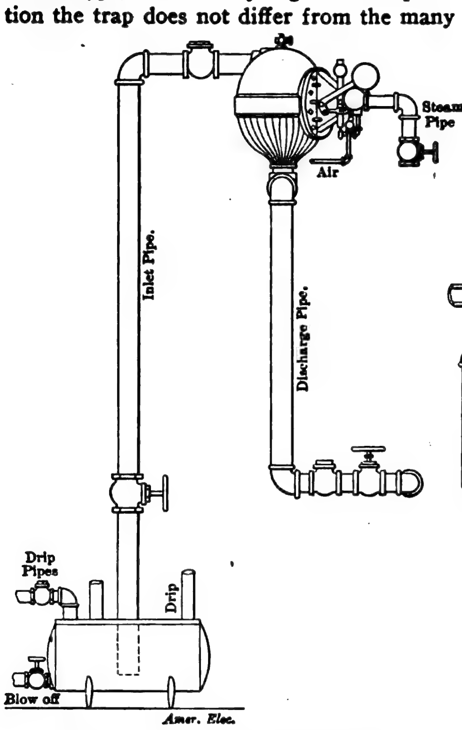

FIG. 23.—"CURTIS" TRAP CONNECTED.

similar traps of this type, the condensation entering at the inlet side and surrounding the float or bucket and lifting the valve to

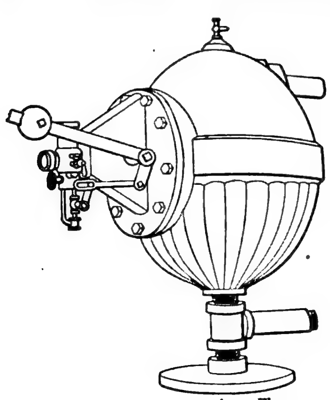

FIG. 24.—"CURTIS" STEAM TRAP.

its seat. The rising water fills the bucket and causes it to sink, thus opening the valve, which permits the water to be forced out of the trap by the pressure of the steam in the drip system. After sufficient water has been discharged out of the bucket to lighten it the water on the outside raises it, and again forces the valve against its seat and the trap is again ready for the next discharge. The float is of pressed steel and rarely gives cause for trouble. The

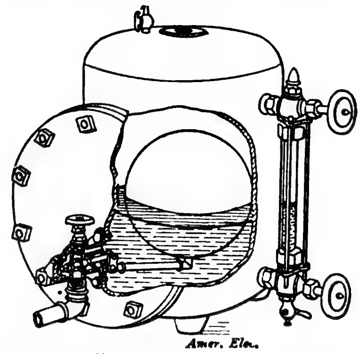

FIG. 25.—"CURTIS" BALANCED TRAP.

body of the trap is large and forms a convenient place for sediment to lodge to be blown out through the drain, the slow rising of the water to the top of the bucket being favorable for this. The valve and seat are located in the top section of the trap, and are thus protected from sediment which lodges in the bottom of the

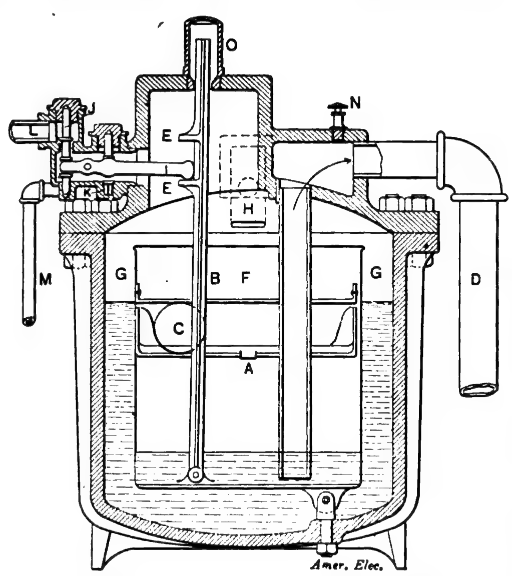

FIG. 27.—ALBANY "CLASS A" STEAM TRAP.

trap. The traps are equipped with a bypass and, if desired, a gauge glass is provided.

The Julian d'Este Co. of Boston, Mass., manufactures a line of "Curtis" traps that includes both the return and the non-return types. The return trap operates practically the same as those already described, being located above the boiler and having the water of condensation forced into it from a receiver by the pressure of the steam in the drip system.

The water rising in the trap raises a float which in turn operates a valve letting full boiler pressure on to the surface of the water in the trap. A check valve prevents the water from returning to the receiver and it flows by gravity into the boiler. The series of movements follows so closely those already described in detail that it is needless to enter upon a further description. Fig. 23 shows a trap applied to a boiler, and Fig. 24 shows an enlarged view of the same trap. Fig. 25 shows the "Curtis" balanced trap, which consists of a cylindrical pot with rounded ends. The operation of the valve is by means of a ball float made of copper. On one side of the body of the trap is a nozzle of sufficient diameter to admit the float. This nozzle is covered with a strong plate to which is bolted the composition valve. The valve consists of two discs of equal area on a single stem, one with a short sliding fit, the other with a ground seat taper fit, which guides it on to its seat, while the valve stem is guided by a spider with three arms, and is loosely connected by a knuckle joint to the float. The valve stem is in two parts, the outer one carrying the discs screwing into the inner one.

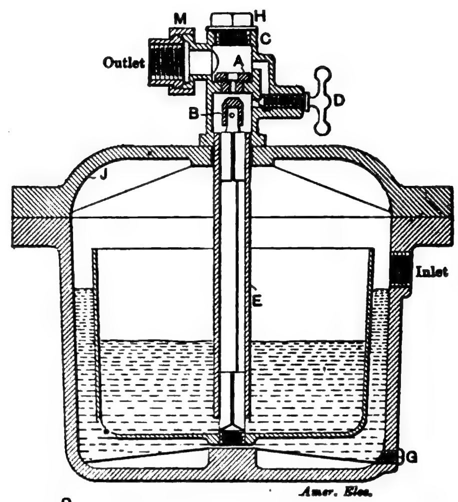

FIG. 28.—ALBANY NON-RETURN STEAM TRAP.

A bucket return trap is manufactured by the Albany Steam Trap Company of Albany, N. Y. It consists of an approximately cylindrical body provided with a closed bottom. A removable bonnet forms the closure for the top of the casing and is secured thereto by through bolts. An open top copper bucket is attached to the casing by a hinged joint in such a manner as to allow it to freely tilt as occasion requires. Channeled guides are arranged within the bucket, and in these guides are rolling counterweights, which complete the tilting movement of the bucket by gravitating to the depressed ends of the guides. A valve-operating rod is connected by a joint to the bottom of the bucket; the upper end of the rod is fitted to move more freely in a chambered guide secured to the bonnet. The rod is provided with tappets projecting laterally, which are adapted to engage against the inner end of the equalizing valve lever. The tappets are spaced such a distance apart as to allow this lever to work freely between them. The purpose of this equalizing valve is to admit live steam direct from the boiler when it is required. The valve is shown connected to the bonnet, the casing which contains the equalizing valve also containing a small exhaust valve.

Water of condensation enters through the inlet check-valve and opening *H* into the space *G* between the bucket and the outer case. The bucket *F* is forced upward by this water, and it is this action of the bucket that operates the equalizing valve *J* and the exhaust valve *K* through the medium of the valve rod *B*. When the bucket is raised sufficiently, the counterweights *C* roll on the channeled guides *A* to the side of the bucket that is adjacent to the hinge joint, thereby providing a sudden impulse to the

tilting of the bucket and making the operation of the equalizing valve more positive.

When the space *G* is filled the water flows into the bucket, which when filled tilts downward, causing the ball weights to roll to the opposite side, giving a sudden impulse downward and bringing the upper tappet *E* on the rod *B* suddenly against the inner end of the valve lever *I*, thus opening the inlet equalizing valve *J* for the admission of steam at boiler pressure. The pressure in the trap and in the boiler now being equal, the water flows by gravity from the trap into the boiler through the syphon pipe *D*, passing through a check valve on the way. When the bucket is emptied of water, it again moves upward, going through the operation just described of closing the equalizing valve *J* and opening the exhaust valve *K* to the exhaust opening *M*. The purpose of this exhaust valve and opening is to allow the escape of any steam that might remain.

The small air valve shown on top of the discharge chamber is to relieve the discharge pipe of air when first placing the trap in operation. An automatic air valve is provided, which is adjusted to relieve any accumulation of air from the trap cylinder during its regular operation. This trap is shown in section by Fig. 27.

A duplex system is also provided for cases where the pressure in the drip system is not high enough to force the water into the return trap; it consists of two return traps, one placed so as to receive the water from the drip system by gravity and discharging it into another trap placed above the boiler which operates simply as a return trap.

The Albany Steam Trap Company also makes two classes of non-return traps, one for pressures up to 100 lbs. and the other for pressures from 100 to 175 lbs. These are called class "C" and class "B." Class "C" trap is shown in Fig. 28, and needs but little explanation. Class "B" is called the high pressure trap and has several features, one of which consists in protecting the discharge valve by a thin disc having in it the proper sized opening to allow the water to flow without undue friction; this disc is placed in the body of the discharge valve outside of the valve seat, and instead of the rapid wearing away of the valve and its seat, the disc, which may be readily replaced, is worn, entailing a minimum expense.

Referring to Fig. 29, it will be seen that the water enters the trap through the inlet pipe *A*, in which there is provided a strainer *B* for preventing dirt and sediment from entering the trap proper. After leaving the strainer the water enters the small chamber *D*, formed in the top casting, running thence through an opening into the space between the casing and the bucket. The rising water carries the bucket with it, thus operating the discharge valve through the guide sleeve and the bell-crank *N*. The valve seat is marked *K*, the valve *H*, and the valve stem *G*. When the bucket has received enough water to seal the lower end of the pipe, *P*, see Fig. 29, the pressure of steam on the trap will force part of the water from the outside of the bucket, as well as some from the bucket, up into the tank *T* through the pipe *P* and the pipe *C*. When the tank *T* is full, the water fills the bucket, which drops and operates the discharge valve. Water is forced out of the bucket through the discharge pipe *E* into the chamber *F* and through the valve *K*, passing through the disc *L*, mentioned above. When enough water has been discharged to uncover the lower end of the pipe *P* steam enters the tank *T*, equalizing the pressure and allowing the water in the tank to flow into the space between the bucket and the outer shell, thus raising the bucket to its highest position and closing the discharge valve. The trap is provided with an air valve.

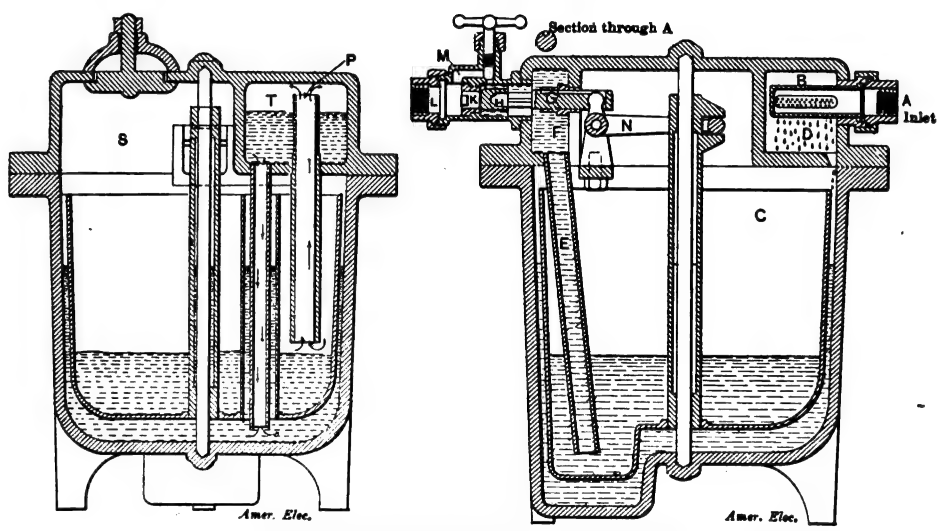

FIG. 29.—ALBANY "CLASS B" STEAM TRAP.

CARELESS HANDLING OF DIRECT-CURRENT MOTORS.

BY W. G. VIALL.

The writer's attention was recently attracted to the instruction card shown in Fig. 1. This card was got out by a central station company for the purpose of instructing anyone whose duty it might be to start and stop any of the motors owned by the company and rented to its customers. Most of the motors were of the Edison bi-polar type and were operated on 500-volt current; wattmeters were used on nearly all of the motors. Fig. 2 is a diagram of the wiring showing the wattmeter connected between the main switch and motor. The single-pole switch referred to in the instructions is mounted on the terminal board of the motor and is used for opening the armature circuit only. The principal feature of this case is the instruction card; by following the directions given more harm would be liable to result than if no directions were given at all. The instructions for starting the motor are all right, as the field is allowed to build

EDISON RESISTANCE BOX.

TO START MOTOR.

FIRST.—See that Resistance is all in.
SECOND.—Close Double Pole Switch.
THIRD.—Close Single Pole Armature Switch.
FOURTH.—Turn out Resistance Slowly.

CAUTION.

Never put a load on the Motor until the resistance is All out.

To STOP MOTOR.

FIRST.—Open Single Pole Armature switch.
SECOND.—Open Double Pole Switch.
THIRD.—After Motor has stopped, turn in Resistance

CAUTION.

Never allow Motor to stand with Brushes off of the Armature.

Cost of repairs caused by not following above directions will be charged to the user.

FIG. 1.—INSTRUCTION CARD.

up to a considerable extent before current is applied to the armature by closing the single-pole switch. It is in the instructions for stopping the motor where the fault lies. Opening the single-pole switch first will cut out the armature and leave the field alive; then when the main or double-pole switch is opened the field circuit will be broken

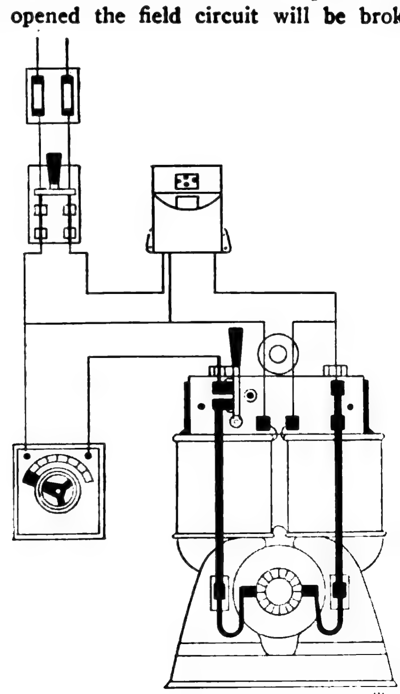

FIG. 2.—DIAGRAM OF CONNECTIONS.

quickly and the reactive kick of the field coils will cause a sudden rush of current through the meter, under a voltage many times greater than the normal running voltage. The result will be a burned-out, short-

circuited or open-circuited pressure coil in the meter, and should there happen to be no meter in the circuit to take up the discharge, the voltage might rise to an instantaneous value sufficiently high to break down the field insulation and ruin the field coils. The first thing to be done in stopping the motor, of course, is to open the main switch, and after the motor stops the single-pole switch should be opened and the starting resistance cut in. By stopping in this way the field and armature would be connected with each other until the motor stops running, and from the instant the main switch is opened the motor will act as a dynamo and supply current to the field from the armature; as the armature gradually comes to a stop the field current gradually diminishes so that when the single-pole switch is opened no current will be flowing in the field circuit.

DISEASES OF ELECTRICAL MACHINERY.

BY F. B. CROCKER AND S. S. WHEELER.

J. Dynamo Fails to Generate.

This trouble is a particular case of the preceding class, "Voltage of Generator Too High or Too Low." It is usually due to the inability of a self-exciting generator to "build up" its field magnetism. The proper starting of such a dynamo requires a certain amount of residual magnetism, which must be increased to full strength by the current generated in the machine itself. This trouble is not likely to occur in a separately excited machine, and if it does it is usually due to the fact that the excited fails to generate, and therefore amounts to the same thing.

Cause 1.—Residual magnetism too weak or destroyed, due to (*a*) vibration or jar, (*b*) proximity of another machine, (*c*) earth's magnetism, (*d*) a strong current through the armature when there is little or no field current tending to neutralize or reverse the field magnetism, owing to the back ampere-turns, (*e*) accidental reversed current through shunt or series field coils, not enough to completely reverse magnetism. The complete reversal of the residual magnetism in any dynamo will not prevent its generating, but will only make it build up a current of opposite polarity. Sometimes reversal of residual magnetism may be very objectionable, as in case of charging storage batteries; but, although the popular supposition is to the contrary, it will not cause the machine to fail to generate. Cases (*d*) and (*e*) are likely to occur with self-exciting direct-current generators working in parallel, or with a storage battery, but not to a single machine.

Symptom.—Little or no magnetic attraction when the pole pieces are tested with a piece of iron.

Remedy.—Send a magnetizing current from another machine or battery through field coils, then start and try the generator again; if this fails, apply the current in the opposite direction since the magnets may have enough polarity to prevent them from building up in the direction first tried.

Shift the brushes backward to make the armature magnetism assist that of the field. Turn machine around or change its polarity, so that the magnetism which the earth or the adjacent machine tends to induce is in the same direction as the residual magnetism. Dynamos should be placed with their opposite poles toward each other, and the north pole of a machine should preferably be placed toward the north (which is magnetically the *south* pole of the earth), but the earth's magnetism is hardly strong enough to reverse or even materially affect the residual magnetism.

Cause 2.—Reversed connections or reversed direction of rotation.

Symptom.—When running, pole pieces show no attraction for a piece of iron. The application of current from another source will not, in this case, make a dynamo generate, as in Cause 1, because whichever way the field is thus magnetized the resulting current then generated by the armature opposes and destroys the magnetism.

Remedy.—(*a*) Reverse either the armature connections or the field connections, *but not both.* (*b*) Move brushes through 180 degs. for two-pole, 90 degs. for four-pole machines, etc. (*c*) Reverse direction of rotation. After each of the above changes the field may have to be built up by applying current as in Remedy I, because the conditions in these cases tend to destroy whatever residual magnetism may have been present.

Cause 3.—Short-circuit in the machine or external circuit.

Symptom.—Magnetism weak, but usually perceptible.

Remedy.—If the short-circuit is in the external circuit, it will prevent the building up of a shunt dynamo until external circuit is opened. But with a series dynamo it will hasten the "building up." If the short-circuit is within the machine, it is likely to prevent the building up of either shunt or series machines and it should be found by careful inspection or testing. In these cases do not connect the external circuit until the short-circuit is found and eliminated. A comparatively slight short-circuit, such as that caused by a defective lamp socket or copper dust on the brush-holder or commutator, may prevent a shunt generator from building up. (See "Sparking," Causes 5 and 8.) Too many lamps or other load might also prevent a shunt dynamo from building up its field-magnetism, in which case the load should be disconnected in starting.

Cause 4.—Field coils opposed to each other.

Symptom.—Apply current to the field coils, as in Remedy I, and the following symptom will exist: If the pole pieces of a bipolar machine are approached with a compass or other freely suspended magnet, they both attract the same end of the magnet, showing them both to be of the same, whereas they should always be of opposite, polarity.

For similar reasons the pole pieces are magnetic when tested separately with a piece of iron, but show less attraction when the same piece of iron is applied to both pole pieces at once, in which latter case the attraction should be much stronger. In multipolar machines these tests should be applied to consecutive pole pieces.

Remedy.—Reverse the connections of one of the coils in order to make the polarity of the pole pieces opposite. The pole pieces of multipolar machines should be alternately north and south (when tested by compass).

Cause 5.—Open circuit.

This may be due to: (*a*) Broken wire or faulty connection in machine, (*b*) brushes not in contact with commutator, (*c*) safety-fuse blown or removed or circuit breaker open, (*d*) switch open, (*e*) external circuit open.

Symptom.—If the trouble is due merely to the switch or external circuit being open, the magnetism of a shunt-wound generator may be at full strength, and the machine itself may be working perfectly; but if the trouble is in the machine, the field-magnetism will probably be very weak.

A break in the field circuit of a separately excited generator will prevent it from generating, and is indicated by the fact that the exciter has its field magnetism, while the main generator has not. One break in the armature of a direct-current machine does not prevent it from generating but produces sparking (Cause 6). A break in a single-phase armature prevents it from generating; a two-phase or a three-phase Y armature generates single-phase, but a Δ armature continues to give three-phase currents with diminished capacity in amperes.

Remedy.—Make very careful examination for open circuit; if not found, test separately the field coils, armature, etc., for continuity with magneto or cell of battery and electric bell. (See "Motor Stops," Cause 3.)

A break, poor contact, or excessive resistance in the shunt field circuit or regulator of a generator will also make the magnetism weak and prevent its building up. This may be detected and overcome by cutting out the rheostat for a moment, the surest way being to connect the two terminals of the field coils to the positive and negative brushes, respectively.

A break or abnormally high resistance anywhere in the circuit of a series-wound dynamo will prevent it from generating, because the field coil is in the main circuit. This may be detected and overcome by short-circuiting the machine for a moment in order to start up the magnetism.

Either of these two remedies by short-circuiting should be applied carefully, and not until the pole pieces have been tested with a piece of iron to make sure that the magnetism is weak.

Cause 6.—Brushes not in proper position.

Symptom.—The magnetism and voltage are increased by shifting the brushes.

Remedy.—It often happens that the brushes are not set at the proper point; in fact, they may be set exactly wrong, so that the dynamo is incapable of generating any current whatever. This trouble is usually due to the fact that the proper position for the brushes is not the same for all kinds of machines. Almost all ring armatures and many drum armatures require the brushes to be set opposite the *spaces* between the pole pieces. On the other hand some armatures are wound so that the brushes have to

be set in line with the centers of the pole pieces, or in some intermediate position. Most multipolar machines have as many sets of brushes as there are pole pieces, while some have cross-connected armatures or have a series or two-circuit armature winding (for example, railway motors) so that only two sets of brushes are required. Four-pole machines with only two sets of brushes require them to be set at 90°; six-pole machines, either 60° or 180°, and so on.

The fact is, that the proper position of the brushes depends upon the particular winding, internal connections, etc., and ***no one should ever assume to know where to set the brushes unless*** he is familiar with the particular type of machine. A blue print or

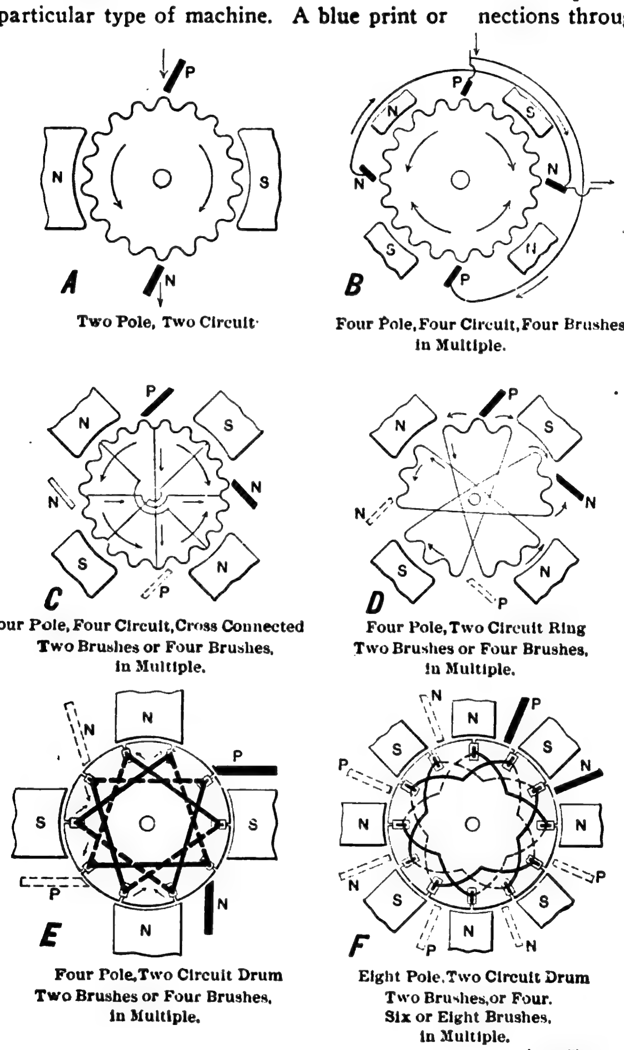

FIG. 1.—PRINCIPLES OF THE CONNECTIONS IN THE DIFFERENT TYPES OF ARMATURES.

other definite instructions should always be obtained and followed, and if these are not available the matter may be determined by careful trial. The proper position of brushes is the same for generators and motors, except that in the former the brushes are given a *lead,* that is, shifted a little in the direction of rotation, whereas motor brushes should be set a little backward. This shifting is necessitated by armature reaction, which distorts the field-magnetism.

The positions and number of brushes for each kind of armature are shown in Fig. 1, which shows also the *arrangements of circuits* in each of the leading types.

A is the armature for the ordinary two-pole machine, and may be drum or ring wound. The current enters (in a generator) through the negative brush, passes around both sides of the armature, and out through the positive brush. Hence this is called a two-circuit armature.

B is a four-pole ring armature, but being similar in principle may also represent a four-circuit drum winding in a four-pole machine. As there are two more poles, it is necessary to use two more brushes to collect the currents. This gives two brushes through which current enters and two through which it leaves; consequently, each pair of brushes must be joined in multiple to carry all the current to the mains.

C is a four-pole armature in which the additional currents are carried across to the first pair of brushes by means of connections through the center of the armature. Therefore, the entire current may be taken off by these brushes, or two more may be added to reduce the heating effect, in which case they must also be connected in multiple to the first pair, as in case *B*.

With either *B* or *C*, since there are two parts of the armature winding, under the influence of different poles, but in parallel with the mains, it is evident that if the electro-motive force in one part of the winding is weaker than in the other, through inequality of the poles or otherwise, it will short-circuit the other part of the winding and give trouble. (See "Sparking," Cause 9.) This does not occur in A, because both parts of the winding are influenced by the two poles of a single magnet. *D* is a four-pole armature in which the windings do not connect together in parallel but in *series,* thus overcoming the above objection. It is a ring winding, and each coil is connected to the one diametrically opposite. An examination will show that though the poles alternate, the wire is all arranged so that the current flows in a single pair of circuits, as in *A*. This also permits of the use of larger wire and fewer turns, as they are connected in series instead of in multiple circuit.

E is a series or two-circuit drum winding corresponding to the ring winding *D*.

To facilitate tracing the course of the current, the arrangement is represented with the smallest possible number of bars. Many more are used in practice.

F is a series or two-circuit drum armature for eight poles. The principle is the same, but the limit of brush adjustment is smaller. The entire range from zero to full e.m.f. is covered by moving the brush one-eighth of the circumference. As the winding is all in series, two brushes only are necessary, but as many more as desired may be added between the other poles, and then connected in multiple to the first ones.

Letters on Practical Subjects

Communications intended for publication in this department must be received at this office not later than the 15th of the month prior to the date of publication.

Mr. Malcolm's Problem in Lamp Connections.

I offer the diagram herewith enclosed (Fig. 1) as a solution of Mr. Malcolm's problem published last month. The switches, *A* and *B*, are evidently double-break knife switches, and in order to avoid any permanent connection between the two branch circuits and also allow the switches both to control the single lamp, the latter is connected to the hinges of the switches.

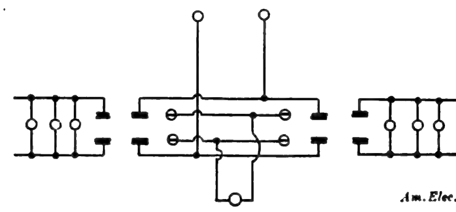

FIG. 1.—MR. BONE'S SOLUTION.

Closing either switch, therefore, will connect the lamp to the supply circuit along with the regular branch controlled by that switch.

Reading, Mich. FRANK W. BONE.

[The same solution was supplied by Messrs. R. E. Gibbs, Springfield, Wis.; Geo. H. Lackey, Long Branch, N. J.; Wilson A. McCown, Ladonia, Tex.; C. H. Pool, New York, and Fred R. Price, Columbus, Ohio.—EDITOR.]

The enclosed diagram (Fig. 2) shows one method of meeting the requirements of Mr. Malcolm's problem. The single or pilot

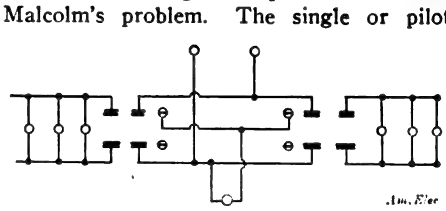

FIG. 2.—MR. CARTER'S SOLUTION.

lamp is connected permanently on one side to the supply circuit, which is permissible with less than 12 lamps, and the other terminal is connected to the hinge posts of the two switches which correspond, when closed, to the other side of the supply circuit. Thus the two branch cricuits are en-

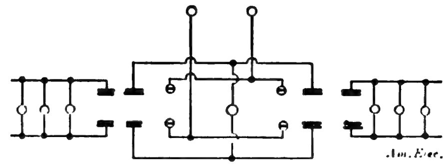

FIG. 3.—MR. BULLARD'S SOLUTION.

tirely independent, as required, and the lamp is lighted when either of the switches is closed.

Baltimore, Md. EDW. G. CARTER.

I submit herewith a diagram of connections (Fig. 3) as a solution of Mr. Mal-

colm's problem published in this department last month. The switches are double-break, with the hinges connected to the supply circuit and the inner jaws to the

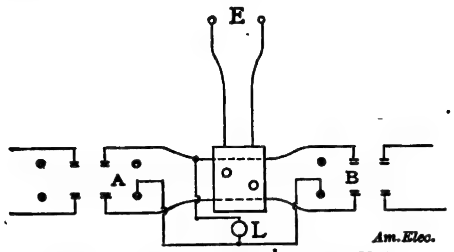

FIG. 4.—MR. MALCOLM'S SOLUTION.

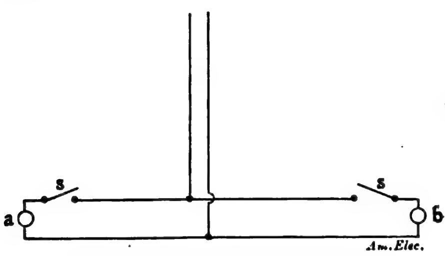
single lamp, so that when either of them is closed it connects its branch circuit and the single lamp simultaneously to the supply circuit, *E*.

Warren, R. I. J. E. Bullard.

[The same solution was furnished by Messrs. Herbert A. Fiske, Kingston, R. I., and Chas. H. Morrison, San Francisco, Cal. The solution of Mr. Malcolm is shown by Fig. 4, which, it will be noted, is practically identical with that offered by Mr. Carter



FAULTY ELECTROLIER CIRCUIT.

(Fig. 2), the only difference being the omission of the branch block, which might or might not be allowable, according to the sizes of wire used.—Editor.]

A Faulty Electrolier Circuit.

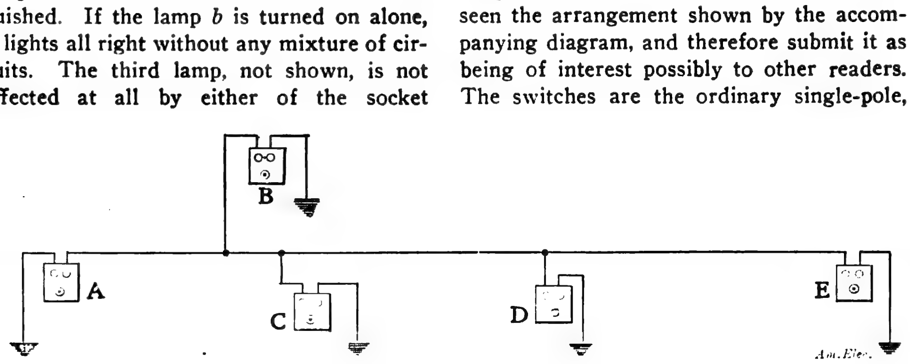
A three-light electrolier carrying 110-volt lamps is connected up in the usual way, the lamps being in key sockets. In the accompanying diagram two of the lamps are indicated by the letters *a* and *b*, and the socket switches by *s* and *s*. When all three lamps are turned off (only two are shown in the diagram), turning on the lamp *b* at the socket lights that lamp and also lights the lamp *b*; when *a* is turned off *b* is also extinguished. If the lamp *b* is turned on alone, it lights all right without any mixture of circuits. The third lamp, not shown, is not affected at all by either of the socket switches of the other two lamps. I should like readers of this journal to suggest what the trouble is; it is very probably a cross or ground of some sort, but it has not been located yet.

Portland, Ore. Leonard F. Fuller.

Problem in Telephone Circuits.

Five telephones are installed on a party line, as indicated by the accompanying diagram. The instrument at *A* is an 80-ohm series set, which was put in by mistake; all of the others are bridging sets of 1600 ohms each. It is impossible to call up station *A* from station *C* direct, but it can be called up from *B, D* or *E* in the usual way. Station *A*, however, can call up any of the others, including *C*, and station *C* can call up any of the others except *A*. I have submitted this to several practical telephone men, but none of them has explained it; perhaps some of the American Electrician readers can work it out.

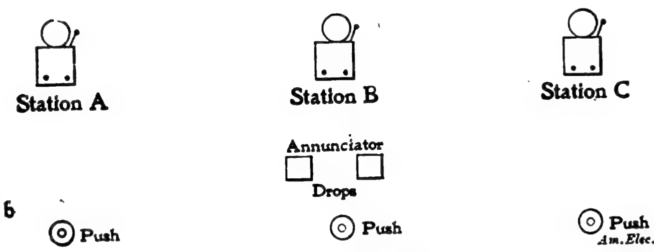
Hackley, Wis. J. R. Brazell.



PROBLEM IN TELEPHONE CIRCUITS.

Another Bell Wiring Problem.

I would like to offer the following problem in bell wiring, for the consideration of your readers: Three stations, *A, B* and *C*, are equipped each with a single-stroke bell



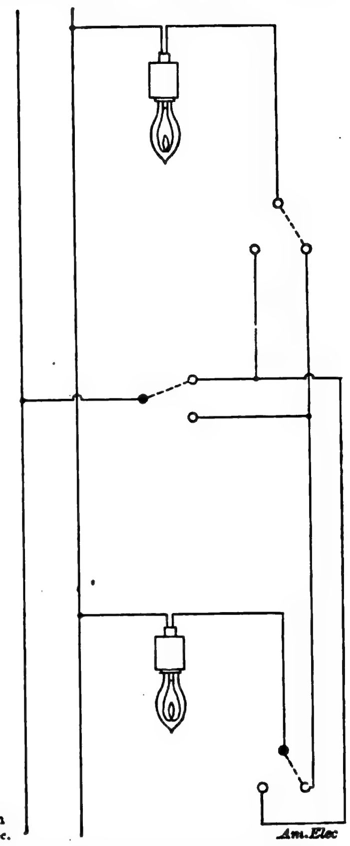
PROBLEM IN BELL WIRING.

and push-button. Station *B* is also provided with two annunciator drops, a second push-button and a battery.* It is required that the push-button at *A* must ring all the bells and throw one of the annunciator drops; one button at *B* must ring the bells at *A* and *B*; the other button at this station must ring the bells at *B* and C; the button at station *C* must ring all the bells and throw the second annunciator drop at station *B*.

Wilmington, Del. William Merrill.

Novel Three-Station Switch Connections.

I have noticed several times diagrams of connections for controlling incandescent lamps from several points, but I have never seen the arrangement shown by the accompanying diagram, and therefore submit it as being of interest possibly to other readers. The switches are the ordinary single-pole, two-way snap switches, connected as clearly shown. The lower lamp and switch are located on the ground floor of a residence, the middle switch half-way upstairs, and the upper switch and lamp in the upper hall. On entering, the lower lamp is lighted by throwing the switch on that floor; when



THREE-STATION SWITCH CONNECTIONS.

half-way upstairs, throwing the middle switch extinguishes the lower lamp and lights the one above, and upon reaching the upper hall, throwing the switch there extinguishes the lamp. This operation may be repeated by the next person coming in, indefinitely, and it may be reversed after any cycle upward, starting at the upper switch and lamp and passing downstairs. The advantage of the arrangement is obvious, and it is the simplest one I know of for accomplishing the results described.

Tacoma, Wash. A. R. Haynes.

*Through an error, the battery and one of the buttons at station B have been omitted from the diagram.—Editor.

Mr. Ryder's Transformer Trouble.

Referring to Mr. Ryder's transformer trouble described by him in the last issue of the American Electrician, I would suggest that the primary circuit of the transformer on the left of his diagram was open. In that case, there would evidently be no voltage, across the secondary terminals *B* and *C*, and with three lamps connected across either *A* and *B* or *A* and *C* this secondary current from the "live' transformer would have to pass through half of the secondary winding of the "dead" one. The counter e.m.f. of this coil would cut down the voltage actually delivered to the lamps.

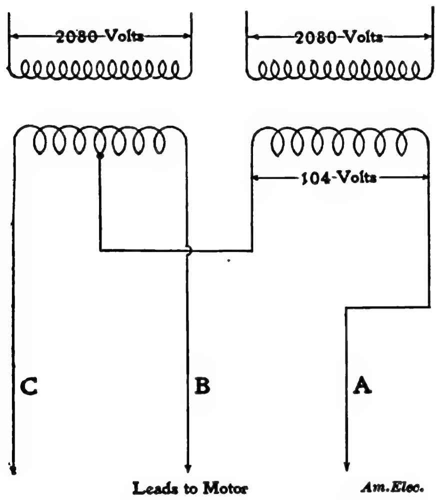
Granite, Ill. Harry C. Coates.

Mr. Ryder's transformer trouble could have been due to the primary fuses of the transformer *B-C* being blown, leaving that transformer dead. Under this condition, a lamp connected across *A* and *B* would receive practically full voltage because the reactive effect of the half of the secondary

B-C would not be high enough with so small a current to cut down the voltage appreciably. Adding more lamps, however, would increase the current through half of the dead secondary winding, and increase its choking effect, thereby reducing the voltage at the lamps. The same is true of lamps connected across *A* and *C*, while no voltage at all would be obtained across *B* and *C* because there would be no primary current in that transformer.

New York. JOHN D. GILBERT, JR.

Referring to Mr. Ryder's transformer trouble, I would suggest that it was due to the primary of the transformer *B-C* being open, probably at the fuse-block. Under this condition, with lamps connected across *A* and *B* or across *A* and *C*, one half of the secondary of the transformer *B-C* would be



MR. RYDER'S TRANSFORMER TROUBLE.

in series with the lamps and act as a choke coil to reduce their voltage; this choking effect would, of course, be greater as more lamps were connected up, reducing the effective voltage still further. The opening of the primary of the left-hand transformer would also explain the absence of secondary voltage across *B* and *C*.

HENRY MULFORD.

Patchogue, L. I., N. Y.

[The foregoing explanations of Mr. Ryder's trouble are correct. The correct cause of the trouble was also explained by Messrs. F. W. Cerny, Mesa, Ariz.; Fred. R. Price, Columbus, Ohio, and C. C. Webster, Schenectady, N. Y., in briefer form.—EDITOR.]

Questionable Solutions.

I wish to call attention to Mr. L. P. Brode's solution to my problem in storage-battery connections which appeared in the June number. In this diagram, the wrong polarity will result when the portable cells are charged from the cells *XYZ*. When the latter cells are in series with the portable cells the connections shown are right, but when cells *XYZ* charge the portable cells *P* the polarity is reversed. This is also true of the other solutions.

Brookline, Mass. E. L. LINCOLN.

I think that some of the solutions printed in this department of the June number are questionable.

As shown in solutions of Mr. Turner's problems in telephone connections by Messrs. Brode, Bethel and Malcolm, in ringing a station via ground return, part of the ringing current will also branch through one of the stations and ring back on the other side of the line to the third station, to ground, thus ringing the whole three stations. Mr. Brode's solution seems to be the best offered.

Mr. Petry's problem of bells operated from 110 volts is not feasible, as answered by Mr. Bethel and Mr. Dillon, in the June number, unless high resistance bells are used. In Mr. Bethel's solution, the voltage would be too high, which, with a few low resistance bells, would cause excessive sparking, and with high resistance bells, the ad-

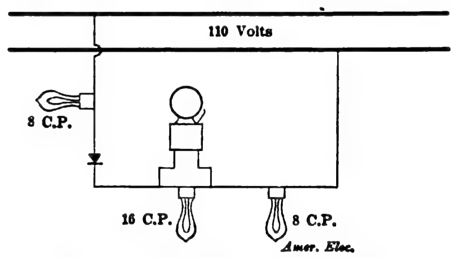


FIG. 1.—MR. LOVELAND'S SOLUTION.

dition of condensers or high resistance, non-inductive resistances bridged around the bells would be needed, for the same reason. Mr. Dillon's solution would not be practical for more than three or four bells, and would also spark. Both solutions are open to the objection that the Fire Underwriters would make to running high voltage without any resistance on low insulated apparatus, such as bells and buttons. There is a slight error in the drawing, as shown in the solution by Mr. Merrill, but the scheme is more commendable, both for safety and practicability. I might add that I have operated low resistance bells on both direct or alternating 110-volt circuits by the method shown in Fig. 1. For large bells, increase either one or both of the two outer lamps as needed.

Philadelphia, Pa. W. A. LOVELAND.

Question Regarding Motor Control Starting Apparatus.

Referring to the article in the June number on "American Types of Control Apparatus for Direct-Current Motors," the author states that the arrangement shown in Fig. 2 is being superseded by that shown in Fig. 1.

The writer installed and started a 20-h.p., 220-volt motor recently, the starting box of which was connected up as shown in Fig. 1. Upon starting the motor light it seemed to act normally, except that there was too much flashing on the contacts of the starting box the first two or three steps. Upon putting on a belt connected to a countershaft, which represented probably 6 per cent of the rated load, the motor would make a few revolutions and then stop, the armature taking a very heavy current, of course, as there was no circuit-breaker in circuit, except an ordinary fuse.

The rheostat being of different make than the motor manufacturers had been sending me, I examined the internal connections and found them as in Fig. 1. I changed the field connection so as to make it correspond to that shown in Fig. 2, and the motor would then start under full load with apparent ease.

With connections as shown in Fig. 1 there is no field until the starting arm reaches the first step, and then the whole e.m.f is impressed instantaneously on the armature terminals. There being no field, practically, as there is an appreciable time element in building up the field, there is an extra heavy rush of current in the armature which seems to neutralize or react on the field

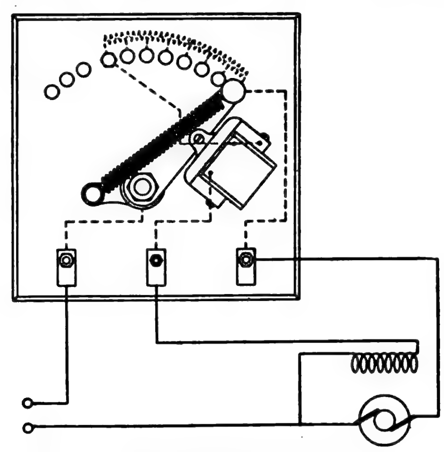

FIG. 1.—QUESTION IN MOTOR CONTROL.

in such a manner as to prevent it from building up. The line drop in this instance is not sufficient to account for the action of the motor.

After changing the starting box connections we had a full field as soon as the main switch was closed. This prevented such a sudden rush of current through the armature, and gave it time to speed up and produce the counter electromotive force necessary to hold the voltage up at the field terminals.

The above explanation of the action of the current in the two instances may be crude, but I believe it is, in the main, correct. If so, why are the connections in Fig. 1 advisable?

Alamogorda, N. M. M. H. FISHER.

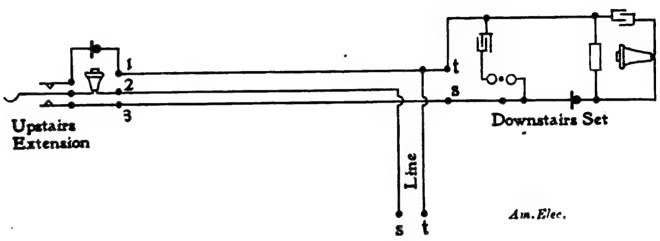
We Stand Corrected.

I note in your "Questions and Answers" of the June number the query as to the difference in the induction coils in the Stromberg-Carlson system and those in the Hayes system, 24 volt. The answer stated that there is no induction coil in the instrument in the Hayes system, but there are repeating coils at the exchange. I beg leave to correct this statement as the Hayes system uses both the induction coil at the subscriber's station and the repeating coil in the cord circuit of the exchange. The difference in the induction coils of the two systems is that in the Hayes system the secondary side of the coil is bridged with the condenser. This gives what is generally called condenser transmission. The charged condenser is the virtual local battery for

the varying resistance of the transmitter.
La Crosse, Wis. C. D. ENOCHS.

Extension Telephone Trouble.

I have a telephone of the central-energy type in the lower part of my house, and have connected an extension set in the upper story, both sets being represented by A and B, respectively, in the accompanying sketch. B was connected so that a conversation carried on at A could be heard by having the receiver at B in series with the sleeve (S) side of the line, with the



EXTENSION TELEPHONE TROUBLE.

hook-switch down. The transmitter and receiver are in series with each other and bridged across the line when the hook-switch is up. By raising the hook-switch at B, A should be cut out of circuit. Disconnecting lines 1 and 3 at the binding posts and holding a receiver to the ear, causes a faint buzzing to be heard. If the shield of B is touched, this buzzing is intensified. According to the circuit, A should not be able to hear a conversation carried on at B; but one can hear indistinctly what is being said at B. The three wires from A to B are run outside the building a distance of about ten feet and are not on insulators. I would like to have some of the readers of the AMERICAN ELECTRICIAN offer their opinion as to the cause of this trouble and its remedy.
Cleveland, Ohio. H. M. WOLF.

Peculiar Static Effect.

I was recently called into the office of a specialist on static treatment to remedy a peculiar fault. It appears that in treating patients their hands and faces would at times become black, especially if the weather were cold. I made a thorough examination and found that this peculiar condition only occurred when the chair was positive and the crown over the head negative. Searching around for a probable cause, I discovered that there were open fireplaces with five oil heaters used to keep the room warm. The minute carbon particles given off by the burning oil could, of course, not be seen; but their presence was evidenced in the faces and hands of the patients. By reversing the polarity of the chair and crown, the phenomenon could not be obtained, nor could it be duplicated on days when the oil stoves were not burning.
Washington, D. C. C. W. PETRY.

Electric vs. Hydraulic Elevators.

I have noticed from time to time various articles in the technical press comparing the electric and hydraulic elevators, and give herewith my own observations regarding the cost of operating and repairing both types. We have in operation here a direct-connected electric elevator supplied with 500-volt direct current from the circuits of the local electric light company. This elevator has been in operation for 3 years and 6 months, six days in the week. During that time it has never been shut down for repairs, and the total amount of money spent on it has been about $4. We purchase power on a flat rate of $15 per month. Hydraulic elevators in this vicinity cost about five cents per trip irrespective of repairs. Of course there are electric elevators on the market which require more care than others; but ours is both reliable and economical.
San Antonio, Texas. R. E. WITTING.

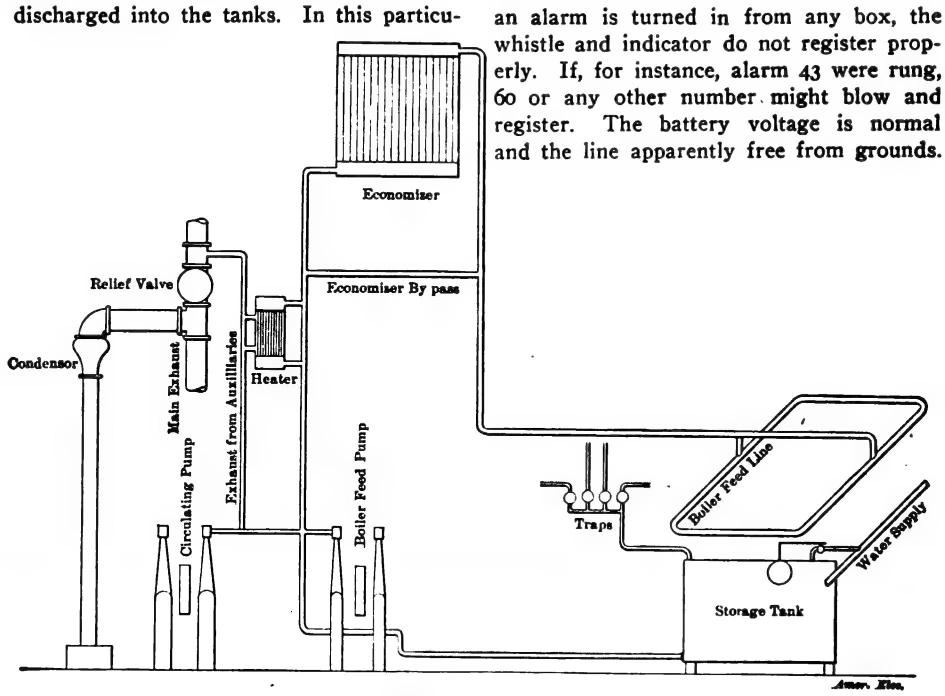
Feed-Water System of a Large Power House.

Herewith find a diagrammatic layout of the feed-water system of one of the large power houses in New York City.

It will be seen by reference to the engraving that the water enters the building through the pipe marked "water supply" and passes into a storage tank through a ball-cock which governs the quantity of water discharged into the tanks. In this particular installation there are nine tanks, each supplied from the main through a ball-cock and connected together by means of an equalizing pipe which is provided with all necessary valves for the purpose of cutting out any desired tank. The sketch shows the piping for one unit, each unit being a duplicate of the other and being cross-connected so that any set of pumps may be used to supply any heater or economizer. Any unit in the system may, of course, be cut out without in any way causing inconvenience.

After leaving the feed pump the water passes into a closed heater, thence through the economizer into the boiler feed line. From this line branches lead directly to the boilers. It will be noticed that by-pass piping is provided for cutting out the heater or economizer, or both. Attention may be called to the fact that the exhaust from all the auxiliaries is passed through the heater before entering the main exhaust pipe to the atmosphere. Traps on the drains from the high-pressure steam line may be discharged into the storage tanks as shown, thus getting the benefit of all of the water of condensation as well as the heat contained therein.

No attempt has been made to show any of the valves, etc., the purpose of the sketch being principally to show a desirable general arrangement or order of continuity for the water from the main to the boiler branches. The number and location of valves may be varied to suit the ideas of the designing engineer or to conform to the depth of the owner's pocketbook.
Brooklyn, N. Y. THOMAS P. MORGAN.



FEED-WATER SYSTEM OF A LARGE POWER HOUSE.

Fault in Fire-Alarm System.

About three years ago there was installed in this town a Gamewell fire-alarm system. The wires were not soldered at any of the connections and the work was performed in a very slipshod fashion, with the result that we have had trouble now and then. If an alarm is turned in from any box, the whistle and indicator do not register properly. If, for instance, alarm 43 were rung, 60 or any other number might blow and register. The battery voltage is normal and the line apparently free from grounds. I would like some of your readers to consider the problem and tell where the trouble might lie.

H. C. PARRISH.
Great Barrington, Mass.

Questions and Answers

Inquiries not accompanied by the name and address of the inquirer, will not receive attention.

What size of wire should be used to connect up a 110-volt, 1-h.p., alternating-current motor 25 feet from the source of current? M. H. B.

No. 12 wire, B. & S. gauge.

How much power will a 45-inch Sampson turbine give under a head of 15 feet? What will be the approximate speed? W. R.

About 238 horse-power at 140 revolutions per minute.

Why is it necessary to use one cored carbon in an alternating-current arc lamp? H. F. K.

Because with solid carbons the arc wanders, or travels around the edge of the carbon tip; the cored carbon centers it.

Please give data for a jump spark coil. F. H.

Presuming that you have in mind a coil for gas engine ignition, the data are as follows: Core, 1½ inches diameter and 8 inches long; winding, 13 layers of No. 16 double-cotton-covered magnet wire.

How many cells of gravity battery would be required to charge four small storage cells? (2) Should the gravity battery be connected to the storage cells all the time? L. L. T.

If the storage cells are in series, use 20 gravity cells in series also. (2) Yes, if the storage cells are to be used at all frequently.

Is static electricity unidirectional or alternating in character? (2) What is its probable tension, and if alternating, its frequency and wave form? W. N. S.

It depends on conditions. A discharge from a static machine is unidirectional; a lightning discharge is oscillatory. (2) The tension is whatever it is made, in the case of artificial static charges and discharges.

A rotary converter receives 420 volts alternating and delivers 650 volts direct current; is there a gain of power? E. J. K.

Certainly not; volts alone do not represent power. The delivered *watts* are from 3 to 10 per cent. less than the watts received at the alternating-current side, and power is measured in watts.

I am told that it is impossible practically to transmit small powers over considerable distances—two horse-power over a distance of three, five or ten miles. Is this true, and if so, why? R. S.

It is not at all impossible, but the cost of the line makes it commercially impractical. The power could not be sold at a price that would pay interest on the investment and a profit on the cost of power production.

What size of cable or wire must be used to carry 80 amperes 119 feet with not more than 3 per cent. drop; the voltage of the circuit being 240? W. F. R.

The smallest size allowable under the Fire Underwriters' Rules is No. 2 rubber-covered or No. 4 weatherproof; the drop will be considerably less than 3 per cent. with No. 4 wire and still less with No. 2, of course.

Can a 500-volt, shunt-wound motor, rated at 1.05 amperes, be changed to a series-wound machine successfully? There is a single field coil of No. 30 s.c.c. wire. C. C., Jr.

You might try rewinding the field coil with No. 20 s.c.c. wire, making the new coil occupy the same space now occupied by the shunt coil. The speed will, of course, be greatly reduced by the resistance of the new field coil in series with the armature.

I have three ordinary vibrating bells arranged to be rung simultaneously from any one of three push-buttons, as shown by the accompanying sketch (Fig. 1), and wish to add a button to ring No. 2 bell alone. Can it be done? W. T. K.

Yes; by using a double-contact push button connected as shown by Fig. 2.

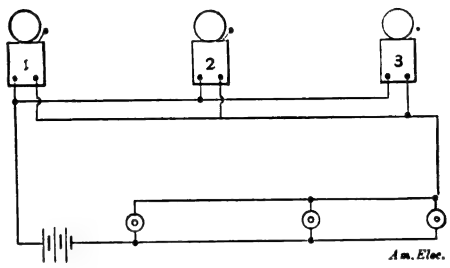


FIG. 1.

What size and type of motors and batteries should be used on the electric buckboard described last month? (2) Can any of the parts be bought already made, and where? (3) What is the approximate cost of building the complete buckboard? H. A. F.

The motors are described in this issue and the remaining parts will be described next month. (2) Not so far as we are aware. Parsell & Weed, of this city, however, are arranging to manufacture most of the parts. (3) We do not know.

What is the rule for the reactance of the single wire of a wide loop carrying alternating current, such as a series arc lighting circuit? (2) What is the corresponding rule for a trolley wire with grounded track return? G. K. M.

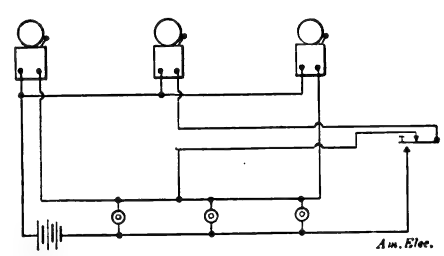

FIG. 2.

There is no formula applicable to such a case. The inductance might be approximated by computing the inductance of short sections of the line by the ordinary formula based on magnetic flux, and adding the results; the reactance is equal to 6.2832 × frequency × inductance. (2) The same as for two parallel wires the same distance apart, except that the track half of the circuit must be considered as magnetic material.

What is the dark deposit that appears on the interior wall of an incandescent lamp bulb after long service? (2) Can the rotational direction of a polyphase induction motor be changed by changing the stator connections? (3) In starting a large induction motor, is the current admitted gradually as in the case of a direct-current machine? L. F. F.

Carbon, from the filament. (2) Yes; if a two-phase motor, reverse the connections of the two leads in one phase; if a three-phase machine, reverse any two of the three primary leads to the machine. (3) Yes, in most cases. In some, however, an auto-transformer is used to deliver a low voltage for starting, and the machine is thrown directly on the full voltage after it gains good momentum.

Is it possible to dispense with platinum leading in wires in incandescent lamps and use a cheaper metal? J. B. N.

Yes, we described some months ago a patented lamp in which copper was used successfully.

What is the relation between an alternating current and a direct current capable of heating a given wire to the same temperature? (2) If the two currents have different values, why is it? (3) Why is it desirable to put external resistance in the armature circuit of an induction motor? J. S.

The alternating current must have a mean effective strength equal to the steady strength of the direct current to produce the same heating effect in a non-inductive conductor; the maximum strength of the alternating current, therefore, is 1.4 times the strength of the direct current. (2) The effective values are not different. (3) In order to cut down the rush of starting current, as in a direct-current motor, and also to improve the power factor of the motor at starting.

How can a dynamo built to give 50 volts and 80 amperes be changed to run as a 110-volt motor? The armature is wound with 55 coils of 2 turns each, the conductor being 4 No. 13 wires in parallel. (2) How can the buzzing in telephone receivers, due to the ringing generator, be obviated? E. F. H.

Rewind the armature with 110 coils, each having two turns of two No. 13 wires in parallel and cut out one coil, leaving 109 coils active. Substitute a commutator having 109 segments. Rewind the field with wire three gauge numbers smaller than that now on it making the new coils fill exactly the same space now occupied by the old ones. The speed will be about 10 per cent higher. (2) Only by putting in a different generator built especially for the purpose by a standard manufacturer.

Is the humming in an alternating-current magnet and its armature due to the vibrations of the laminations or to the rattling of the movable parts of the mechanism? (2) Is the core laminated to prevent eddy currents in it or loss by hysteresis? (3) Does it matter if the armature of an alternating-current magnet is reversed in its relation to the poles after it has been in service some time? J. N. L.

Both, but the mechanism usually causes most of the humming. (2) To reduce the eddy currents in the core. (3) Not at all.

What is the difference between foot-pounds and pound-feet? N. B. S.

The foot-pound is the unit of work done in moving a mass through a distance; multiplying the pressure (in pounds) against which a mass has to be moved (including its own weight if the motion be vertical) by the distance (in feet) gives the work done in foot-pounds. The pound-foot is the unit of angular torque; if a pull of 10 pounds is required at the periphery of a wheel three feet in diameter in order to turn the shaft on which the wheel is secured, the torque will be 10x1.5 = 15 pound-feet.

NEW TYPE OF MOTOR-STARTING RHEOSTAT.

Fig. 1 herewith shows a new type of motor-starting rheostat, brought out by C. W. Landers, of San Francisco, Cal., whose object was to design a motor-starting device that would not stick after use for some time, but could always be relied upon to release when the current is shut off or fails. The illustration is nearly self-explanatory. The cast-iron frame forms the back and top of the starter and the resistance takes the form shown. A rod attached to the hand lever passes through the cover and through all the resistance coils and has a disc attached to its lower end. As the handle and rod are raised this disc picks up the coils one by one and short circuits them. When the handle reaches the top it is held by the retaining magnet, the resistance coils being all cut out and held firmly together. The maker claims several points of merit over existing starters, chief among which is the manner in which the resistance wire is mounted on the frame. This is said to produce a magnetic flux which extinguishes the arc when the circuit is broken. No arcing is said to be perceptible between the plates of the resistance coils, but in the large sizes the plates are provided with carbon trailers mounted on the disc surfaces. By removing the handle and the retaining magnet, and substituting a solenoid lifting coil at the top of the controller and attaching the plunger to the lifting rod and dash-pots at either top or bottom of the rod, an automatic motor starter results. It will be noted that when used in this manner the weight that the solenoid will be called upon to lift is at first small and increases as the solenoid increases its pull. The device is said to be positive in action at all times.

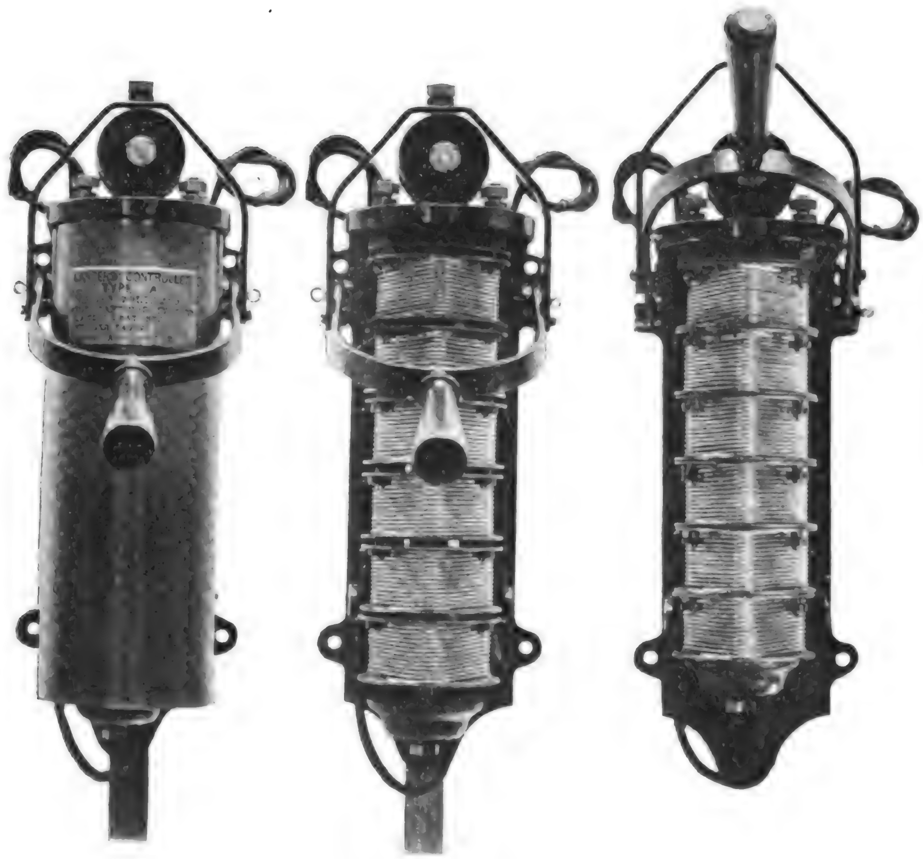

FIG. 1.—LANDERS MOTOR-STARTING RHEOSTAT.

CARBON REGULATOR FOR AUTOMATIC BOOSTER CONTROL.

During the past year the Electric Storage Battery Company has developed and standardized a new method of automatic booster control for regulating the charge and discharge of batteries installed for rapidly fluctuating railway work. This special apparatus, which has been perfected for this purpose, is what is known as the carbon regulator. It consists of a number of piles of carbon discs which are subjected to the varying pressure of a lever, from one end of which is freely suspended the soft iron core of a solenoid which carries the entire generator load, while to the other end is attached a helical spring, whose tension may be adjusted by hand to counterbalance the pull of the solenoid at any desired load on the machines. Slight variations of load above or below this amount will cause changes in pressure on the carbon piles resulting in wide variations in their contact resistance. Advantage is taken of this resistance variation to control the field excitation of the battery booster, usually through the intermediary of a small exciter between whose fields and the carbon piles connections are made similar to those of a Wheatstone bridge, the current in the exciter fields varying in direction and amount with changes in the pressure on the carbon piles. This regulator, while simple in construction and mechanically rugged, is found to be exceedingly sensitive, and a very small proportion of the load fluctuations on a railway plant, getting back to the generators through the solenoid, will cause the battery to charge and discharge, relieving the machinery of the balance of these fluctuations.

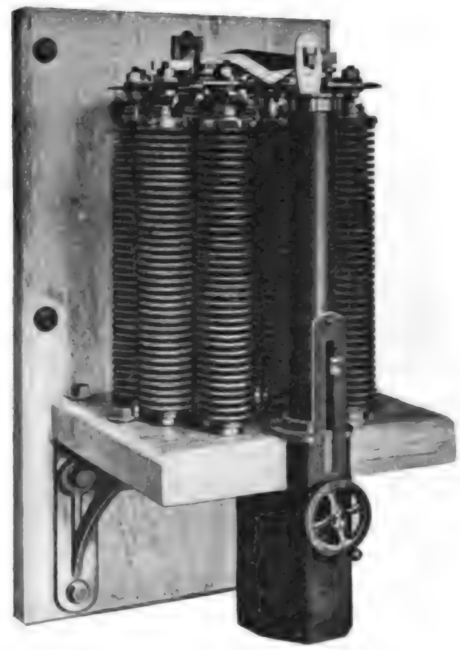

FIG. 1.—CARBON REGULATOR.

The constant load falling on the generators may be adjusted at any desired point by adjusting the tension of the spring above mentioned, which adjustment is instantly made, and may be altered from time to time during the day to meet changes in the load conditions; the battery either simply "floating" or taking a continuous peak discharge or a net charge, according to the adjustment, while always taking automatically the momentary fluctuations of load. The regulator, which is illustrated by the accompanying engravings, occupies about the same space on a switchboard as a watt-hour meter. Fig. 2 shows the solenoid in the generator circuit at the back of the board.

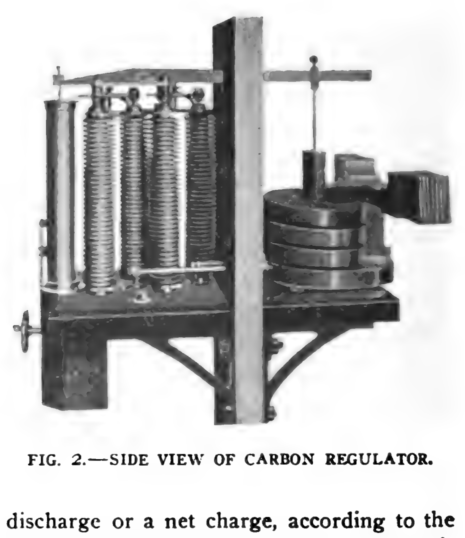

FIG. 2.—SIDE VIEW OF CARBON REGULATOR.

New Apparatus and Appliances

BELT-TYPE, ROTATING-FIELD ALTERNATORS.

A line of belted-type, self-contained, rotating-field, alternating-current generators, such as shown herewith, has recently been placed on the market by the Westinghouse Electric & Manufacturing Company. The machines are built for single, two and three-phase circuits, in sizes from 30 to 200 kilowatts. The single-phase generators are manufactured for 220, 440, 1100 and 2200-volt circuits at 7200 alternations, and besides these the polyphase machines are wound for 6600 volts and both 3000 and 7200 alternations.

The frame of the stationary armature is cast in one piece with slots machined on the inside for holding the punchings which receive the windings; these are composed of wire, strap or bars, depending on the size and voltage of the generator. Open slots are employed in machines up to 75 kilowatts, with coils held in place by hard fibre wedges. In the larger machines partially closed slots are used. Horizontally split brackets which carry the bearings are bolted to this cast-iron frame. The bearings are generous in their dimensions and are self-oiling, having oil rings and an oil gauge with large foundation areas and suitable belt tighteners. These generators may also be arranged for direct connection to an engine or water wheel.

The fields of the smaller generators are of cast steel with pole caps of the same material. The poles of larger sizes are laminated and keyed or dovetailed to a cast-iron spider. The field coils are composed of square wire so wound as to expose the maximum surface. In the generators having laminated poles heavy brass wedges, which hold the field coils in place, retard any shifting of the field between the poles, insure satisfactory parallel operation of two and thus, it is claimed, practically eliminate pumping between the generator and any rotary converters or synchronous motors which may be connected in the system and or more generators.

FIG. 1.—ROTATING FIELD ALTERNATOR.

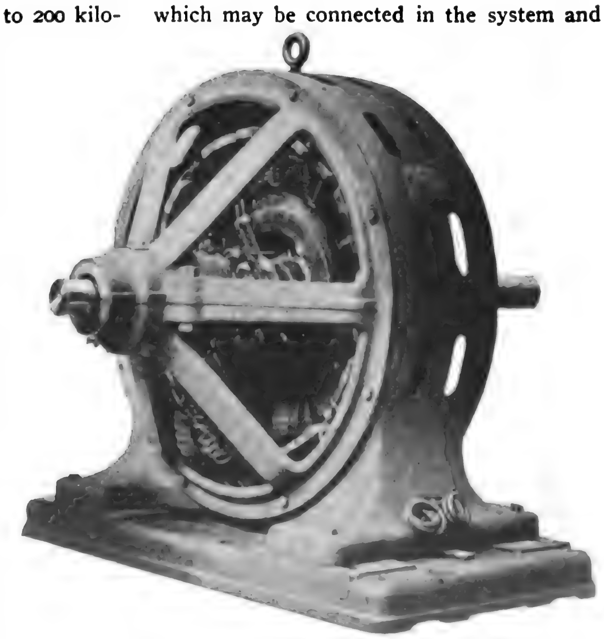

FIG. 2.—ROTATING FIELD ALTERNATOR.

Every means has been utilized for the rapid dissipation of heat from the machines. Open spaces in the laminated field register with those in the armature, and during operation air is drawn in through the field spider and forced out through the stationary core and windings, thus insuring low operating temperature. Excellent regulation is said to be obtained by properly proportioning the armature and field windings in preference to saturating the magnetic field.

The single-phase generators have compensating field windings supplied with rectified alternating current. A commutator on the shaft adjacent to the collector rings has its brushes connected to the secondary of a series transformer in the armature circuit and its segments to the self-exciting field coils. The compensating winding is so designed, the maker claims, that the generator can be adjusted for a practically constant voltage from no load to full load or for an increase in voltage.

FAINT PRAISE.

In the description of the Fort Wayne Electric Works prepayment meters which we published last month, the statement was made that the meters were said to be "reasonably reliable and accurate." This was intended to read "unusually reliable and accurate."

A NEW FOUR-VALVE ENGINE.

The Atlas Engine Works, of Indianapolis, have recently placed on the market a new type of four-valve engine, in which especial attention has been given to the matter of steam economy; and a number of very radical improvements have been made with this in view. Chief among these is the placing of the steam and exhaust valves directly in the cylinder heads, rather than at the top and bottom of the cylinder. This results in a reduction of practically 4 per cent. in the clearance, and the saving of steam effected in this way is quite material. This also involved keeping the entire top of the cylinder and the upper portion of both heads constantly in contact with live steam, in this way greatly reducing the loss from cylinder condensation. The bell crank and toggle joint have been entirely done away with, and a great deal of the lost motion has in this way been eliminated. The steam valves are operated directly from a movable eccentric forming a part of the automatic shaft governor, and are entirely independent of the exhaust valves. The latter are operated from a fixed eccentric on the main shaft, in this way insuring uniformity of compression under all conditions of load and pressure. The connections are all of the "straight line" type, and involve no multiplicity of parts. Both the steam and exhaust valves are double ported, and it is claimed that practically no wire drawing of steam exists in this type of engine. Various tests are claimed to indicate a steam consumption practically identical with an engine of the Corliss type and a regulation of

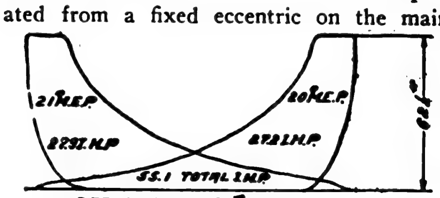

FIG. 3.—CARD FROM FOUR-VALVE ENGINE.

from 1 to 1½ per cent. under changes of load from friction to full rated capacity.

CIRCUIT BREAKERS FOR SPECIAL PURPOSES.

As is very generally known, the Cutter Electrical and Manufacturing Company, of Philadelphia, Pa., manufacture many lines of standard I-T-E circuit-breakers, which are very familiar to the trade. Many special designs are, however, often required to deal with conditions out of the ordinary run of practice, so that a brief description of a tew ot these will not be amiss. Where generators are operated in multiple, in case of accident to one of them or failure of its prime mover, the affected unit is liable to injury from motoring and its fellows are seriously overloaded. To provide against such contingencies the "Reversite" circuit-breaker shown by Fig. 4 was designed. This instrument serves to automatically disconnect the crippled generator before it becomes a tax upon those carrying the load, or before it has attained a dangerous speed due to running as a motor. The results are obtained without the use of relays. A limit switch for the protection of rotary converters is shown by Fig. 5. Where a number of rotaries are connected in multiple on the direct-current side, failure of the current supply of one or more of them, will cause each unit to run as a motor, taking power from the direct-current system. The limit switch is designed to prevent this. The operating coil of this type of instrument is of numerous turns and high resistance, and so connected that when the rotary attains abnormal speed the coil is brought into circuit across the line by a centrifugal device attached to the shaft of the rotary. The instrument illustrated is of 7000 amperes capacity, and is one of a number employed in the sub-stations of the New York Edison Company. Fig. 6 shows a double-pole circuit-breaker having a maximum capacity of 10,000 amperes at 250 volts. It is 30 ins. high, 24 ins. wide, and has a maximum depth of 20 ins. to the top of the operating handle. The illustration shows how space is economized by using for switch contact surface both sides of the terminal bars. The powerful toggle-operating mechanism is easy-working. Fig. 8. shows a triple-pole over-load circuit-breaker used for the protection of a three-phase alternating-current generator. It is provided with tripping mechanism in each of the two outside poles so that an over-load on any phase will cause the opening of the circuit. The

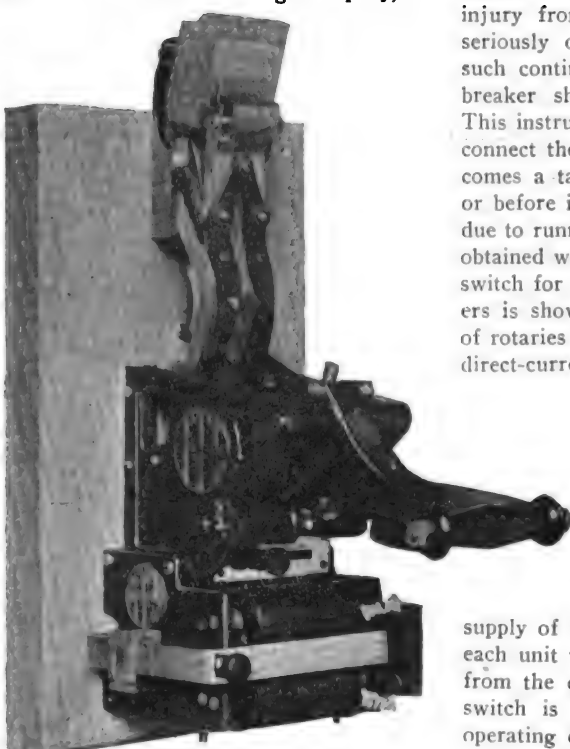

FIG. 4.—"REVERSITE" CIRCUIT-BREAKER FOR OVERLOAD AND REVERSE CURRENT.

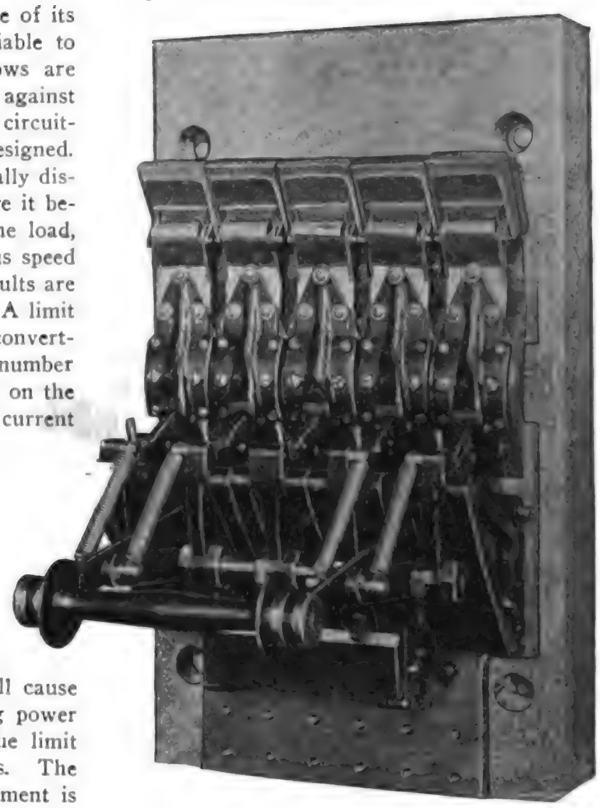

FIG. 5.—CIRCUIT-BREAKER FOR ROTARY.

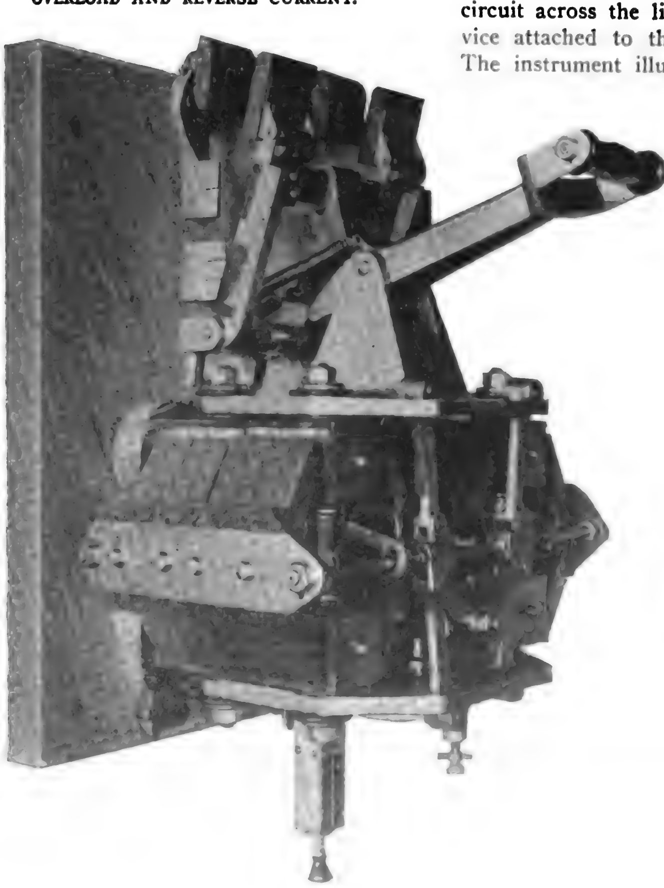

FIG. 6.—LARGE CAPACITY CIRCUIT-BREAKER.

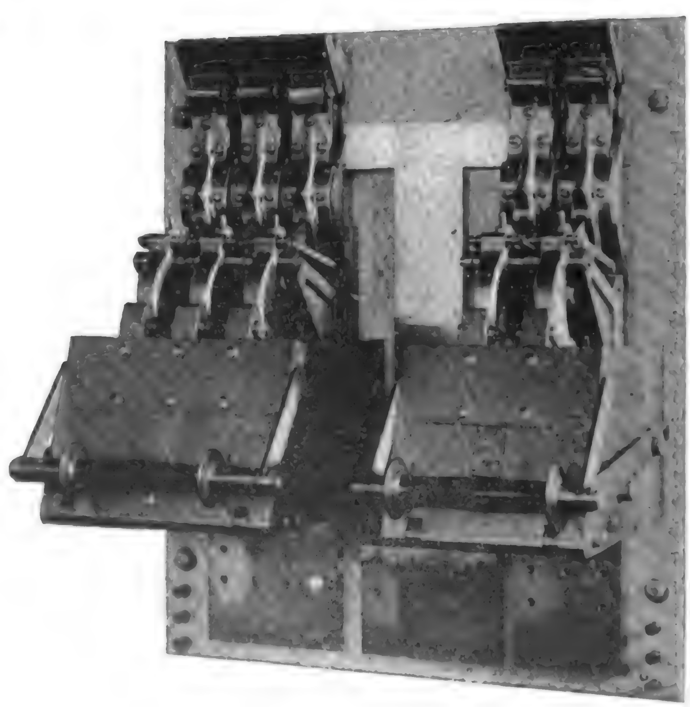

FIG. 7.—REMOTE CONTROL SWITCHES FOR EQUALIZER CIRCUITS.

breaker is also adapted to protect three-phase feeders and three-wire direct-current systems. The closing force is applied through a double toggle. This reduces the strain upon the insulating yoke which unites the poles. A remote-control circuit-breaker for controlling equalizer circuits is shown by Fig. 7. The right-hand switch is of 2000 amperes, the left-hand of 3000 amperes capacity. The upper terminal of each connects with the equalizer main, which takes the place of the equalizer bus otherwise required at the switchboard. The closing magnet is of exceedingly simple construction, and is designed to produce the required force with a minimum expenditure of energy. The exciting coil is liberally proportioned, and its entire exterior surface being exposed to the air, it is not liable to undue heating even as the result of frequent use. The closing and opening coils are brought into circuit by the respective movements of small double-throw switches located upon the switchboard. Remote control switches are also meeting with growing favor as a means of controlling generator, booster and feeder circuits from a distance.

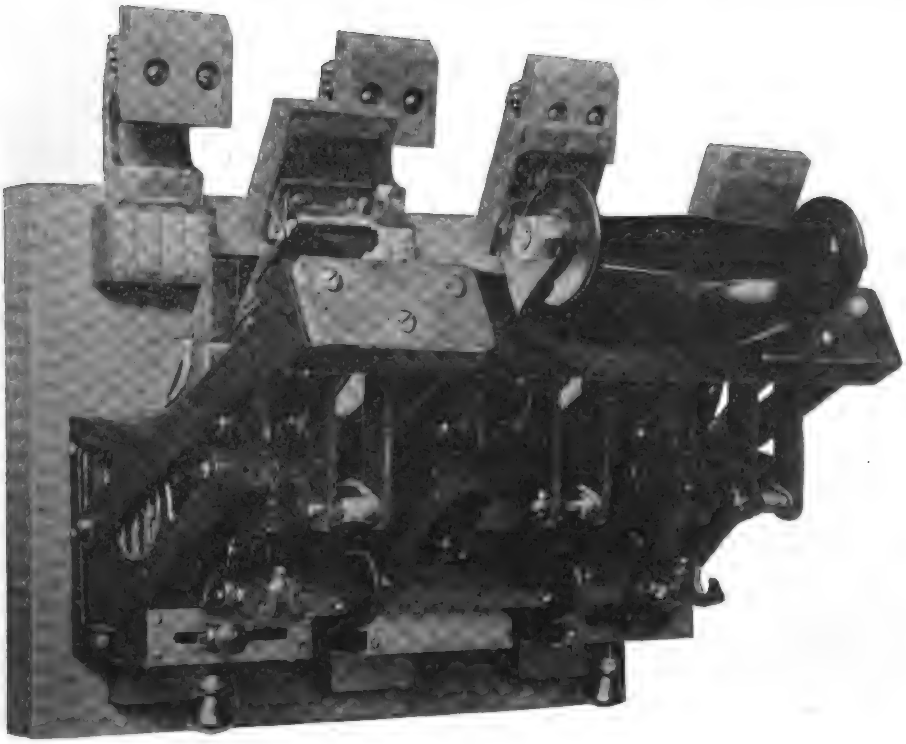

FIG. 8.—TRIPLE-POLE CIRCUIT-BREAKER WITH TANDEM TOGGLE CLOSING MECHANISM.

LIFTING MAGNETS.

The Electric Controller & Supply Company, of Cleveland, Ohio, has designed, built and tested magnets for handling iron and steel in every form, including pig iron, light and heavy melting scrap, steel ingots, blooms, billets, slabs, plates, sheets, rails, structural shapes, spikes, rivets, cotter pins, etc. A single design of magnet is, of course, not adapted to handling the full range of material mentioned; but a different magnet is not required for every different kind of material. The pig magnet, shown by Fig. 9, for instance, will handle with equal efficiency pig iron, scrap, rivets, nuts or any similar material in bulk. The magnet is suspended from the hook of a crane, direct-current at any of the common voltages being employed for energizing the magnet. The magnet is lowered upon the material to be lifted, and the switch closed, thus causing the magnet to attract and hold the material, which may then be hoisted by the crane and transported to the desired point, when by simply opening the switch it is released. Comparing this method of operation with the common methods of connecting the load to the hook of the crane with chains, hooks or clamps, the saving in both labor and time is apparent; as, in general, the attachment of the magnet to the load, as well as the release of the load, may be accomplished by the crane operator without assistance, thus saving the labor of one or more men for prying up the material, attaching hooks and chains at the point of loading and additional men at the point of delivery for unhooking the load from the crane.

FIG. 9.—PIG-IRON LIFTING MAGNET.

TESTS OF A REEVES ENGINE.

Prof. R. C. Carpenter, assisted by Prof. H. Diederichs, both of Cornell University, have made a series of tests on an engine built by The Reeves Engine Company, of Trenton, N. J., for the purpose of determining its economy and mechanical efficiency, and to observe the general behavior of the engine under various loads and steam pressures.

The engine, a vertical cross-compound, was connected through about 25 feet of 4-in. pipe to two B. & W. boilers. This pipe was one size too small, but was the largest that could be obtained for connection. In order to minimize the effect that the resulting high steam velocity would have, a piece of 6-in. pipe about 30 inches long was interposed to act as a sort of reservoir just ahead of the throttle valve. About 20 feet of 7-in. pipe connected the engine to a Wheeler surface condenser.

A Carpenter throttling calorimeter, placed beyond the throttle valve, served to determine the quality of steam. The steam pressure was determined by a gauge connected next to the calorimeter. The speed was found by a continuous counter, and by hand counter as a check. The continuous counter readings were used in the calculations as being correct.

One Thompson indicator was connected to each cylinder, taking cards from each end by means of a three-way cock. Motion for the indicators was obtained by fastening a rod to each cross-head, the stroke being reduced by means of a reducing wheel fastened to each indicator. The condensed steam was pumped by the air pump alternately into two tanks on scales. Readings of condensed steam weights were taken every five or ten minutes, as the load demanded.

For the purpose of test the engine was fitted with a fly-wheel 5 feet in diameter on the low-pressure side. Upon this wheel was placed the Prony brake for the determination of the developed horse-power. This brake was, in all respects, of the ordinary standard design, the strap being of steel plate, fitted with wood blocks on the inside. The wheel was kept as cool as possible by running cold water constantly into the flanged rim, and taking it out by a scoop. A steady small stream of cylinder oil led under the strap helped considerably in the smooth operation of the brake. By these arrangements as much as 185 developed horse-power was taken off one brake. For the condensing series as high a vacuum as could be obtained was carried. This averaged about 24 inches. For the non-condensing series the air-cock on the condenser was kept open, insuring condensation under atmospheric pressure.

For the condensing runs the engine dimensions were 10½ inches and 20 inches x 14 inches; for the non-condensing runs, 12 inches and 20 inches x 14 inches. This change was effected by taking out a liner the new designs of condensers, now being manufactured by the W. H. Blake Steam Pump Company, of Hyde Park, Mass., were made to cover both types. The new standard designs range in capacity from 600 to water into the condenser and consequent flooding of the engine.

The construction of this machine is compact and simple, all parts are readily accessible. The condenser shown in the accom-

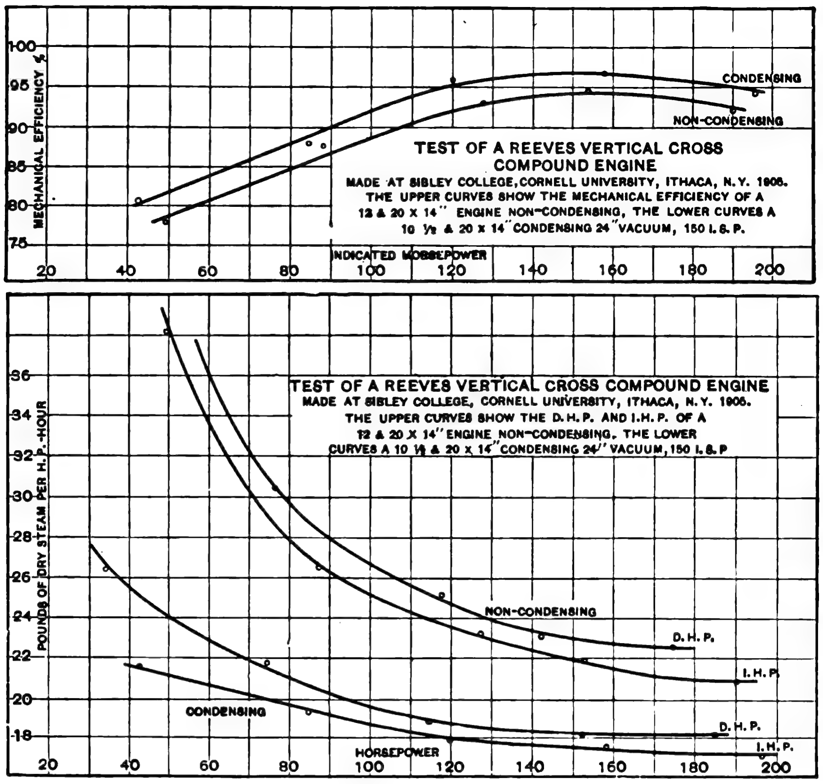

FIG. 10.—TEST CURVES OF REEVES ENGINE.

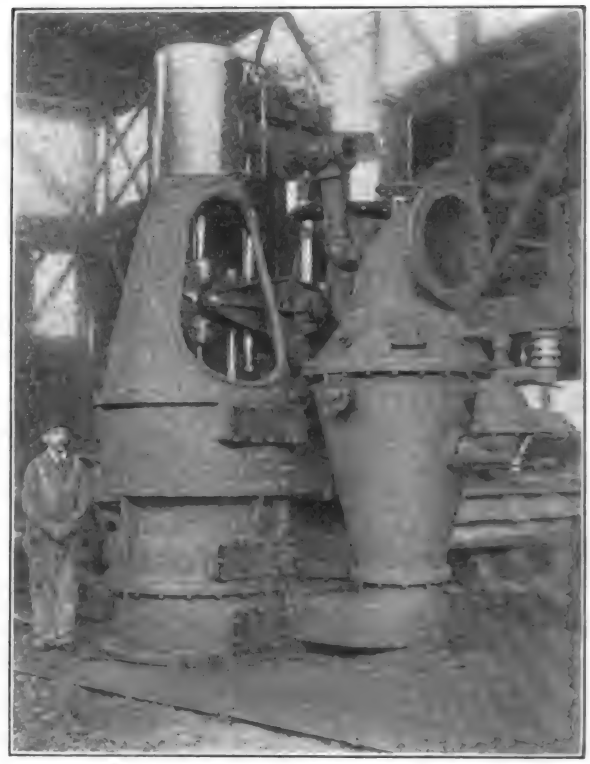

FIG. 11.—TWIN JET CONDENSER.

from the high-pressure cylinder. These dimensions make the cylinder ratio in the first case 3.60, in the second 2.75.

The developed horse-power was found by means of the formula: D.H.P. $= .001492\, n$ for every 100 pounds of net brake load.

The steam consumption per indicated horse-power and per developed horse-power for various loads and steam pressure was computed on the basis of dry steam.

For the purpose of facilitating inspection of results and discussion the water rates and mechanical efficiency are plotted on the accompanying curves (Fig. 10).

Two things are to be noted about these curves. The cut-off even at the high loads does not seem to be late enough to cause any marked rise in the steam consumption at overloads. In fact in most cases little or no rise could be determined. Again, the curves show good economy over a wide range of load. The mechanical efficiency curves show a steady increase with the load at any given steam pressure. On the overloads the efficiency falls off but slightly.

INDEPENDENT TWIN JET CONDENSER.

The advent of the independent air pump and condenser has had much to do with the practical development of the compound engine in medium and small sizes, for with this combination there are now obtainable economic results which not long since were expected only from the large compound engine with direct-connected air pump. That the jet and the surface type of condensers have their respective fields, is clearly recognized; neither type will meet all possible requirements. It was with this in mind that 40,000 pounds of steam condensed per hour with injection water at 70 deg. F. One type is illustrated herewith. The air pump is made with compound steam cylinders, as here shown, with the Blake automatic valve motion, when it is to be operated condensing, and with twin vertical steam cylinders when operated non-condensing and the exhaust steam utilized for feed-water heating or otherwise. The water cylinders are composition lined and all water piston (or bucket) heads are of the same material and fibrous packed. Easy access is afforded to heads, packing and water valves through hand holes on either side of the pump. A special composition is used in the construction of the water valve seats and guards and the studs and water piston rods are of Tobin bronze. The injection stem and cone are of composition, access to the same being provided through hand holes on either side. The amount of water passing through the condenser is regulated by the vertical adjustment of the injection cone which acts as a nozzle to form a thin spray, which is thrown out at an angle of 45 degrees. This falls upon a succession of shelves, thus forming secondary spray through which the exhaust steam from the engine must pass; instantaneous condensation results with economy in the use of water.

In order to prevent flooding of the cylinders of the main engine, an independent vacuum breaker attachment is secured to the side of the condenser; so that when the water reaches the level of the flood chamber the float is raised, and by great leverage forces the check valve from its seat, allowing an inrush of air which instantly breaks the vacuum, thus preventing further suction of

panying illustration is a twin vertical compound jet condenser of exceptional size, having a capacity of 64,000 lbs. of steam condensed per hour with the injection water at 70° F. It has steam cylinders 15 and 30 inches in diameter by 24 inches stroke, and the air cylinders are 38 inches in diameter. The injection inlet is 12 inches, while the discharge is a 20-inch pipe.

APPARATUS WANTED.

We are informed by Mr. W. I. Savidge, Macomb, Ill., that he is in the market for single-phase and three-phase induction motors and a considerable quantity of electric light supplies.

THREE-PHASE TRACTION TO BE INTRODUCED.

The Ganz system of three-phase alternating-current electric traction, which is well known in Europe, is to be introduced on this side. This system, for which much is claimed in the way of cheaper initial cost and operation over the electric railway construction methods at present in vogue in this country, is to be exploited by the Railway Electric Power Company, in which several New York capitalists and railroad men are primarily interested. The company has acquired the electric traction patents and manufacturing rights of Ganz & Co., of Budapest, for the United States, Mexico, Cuba and all the West Indies other than those under British supremacy.

Messrs. L. B. Stillwell, electrical director of the Interborough Rapid Transit Company, and Frank N. Waterman are the consulting engineers of the new company.

THE RISE OF A PROGRESSIVE ESTABLISHMENT.

Fifteen years ago Messrs. Willard W. Low and Thos. I. Stacey decided that there was room for a supply house whose policy would be entirely different from that then in vogue; consequently, the Electric Appliance Company, Chicago, was incorporated, and the business was established in a very small way.

The company also started out with the determination, which has never flagged, to handle only the best specialties.

The first quarters secured by the Electric Appliance Company were at 242 Madison Street, which comprised the first floor only. As the business increased it was found necessary to take in the basement, and about a year afterwards the two upper floors were added, giving ample facilities for handling the business, though it was growing every day. Six years ago it was found necessary, in order to handle the business, to engage larger quarters, and the double five-story building and basement at the corner of Van Buren and Jefferson Streets was secured. This was ample for about two years, at which time warehouse No. 2 was established at 165 South Canal Street, for the accommodation of cross-arms, insulators, electro-galvanized conduit and other heavy and bulky material. This arrangement worked out very nicely until the business had grown so that the company was in danger of losing, on account of being so crowded, its reputation for making prompt shipments. It was then decided that about double the floor space would be necessary. Accordingly last summer architects were given instructions as to what was required in order to make a model supply house handling the large volume of business at that time, also allowing for a considerable increase, and the building that the Electric Appliance Company now occupies at 134-136-138-140 West Jackson Boulevard is the result.

This building is six stories high with a large basement, and has a frontage of 100 feet on West Jackson Boulevard and 100 feet on Desplaines Street.

The general offices of the company occupy the entire second floor, one-half being given to the sales department and the other half to the auditing department.

The remainder of the building is given up to the large stock carried. Two freight elevators facilitate the handling of all material, and the company is in better shape than ever before to not only handle its present business, but to take care of a large increase.

NATIONAL ELECTRIC LIGHT ASSOCIATION CONVENTION NOTES.

THE LOCKE INSULATOR MFG. CO., Victor, N. Y., exhibited a line of its well-known high-tension insulators.

DUNCAN ELECTRIC CO., Lafayette, Ind., had samples of its line of direct-current watt-hour meters on exhibition, in charge of W. H. Sinks.

BUCKEYE ELECTRIC COMPANY, Cleveland, Ohio, was represented by L. L. Sawyer of the Cleveland office.

WESTERN DISPLAY COMPANY, of St. Paul, Minn., had a handsome reflective sign in the corridor adjoining the Convention hall.

WARNER ARC LAMP COMPANY, Muncie, Ind., displayed several types of its arc lamps, the merits of which were explained by Mr. W. F. Warner.

THE COLUMBIA INCANDESCENT LAMP CO., St. Louis, Mo., distributed an attractive leather match box as a souvenir. Mr. J. S. Lehmann was in charge.

BABCOCK & WILCOX COMPANY, New York, exhibited a model of its boiler in the rooms of the Onderdonk Engineering Company, who is its Denver representative.

AMERICAN ELECTRICAL SUPPLY COMPANY, Chicago, was represented by C. E. Browne, who distributed a very useful souvenir in the form of a celluloid hand-bag label.

REYNOLDS ELECTRIC FLASHER MFG. CO., Chicago, displayed the improved Reynolds and Reco electric sign flasher. Mr. I. A. Bennett represented the company.

OSBURN FLEXIBLE CONDUIT COMPANY, New York, showed samples of its well-known Flexduct conduit and distributed tasteful scarf pins.

BRYAN-MARSH COMPANY, Chicago and New York, sent E. H. Haughton to interest central station men in the well-known Imperial incandescent lamps manufactured by the company.

MOLONEY ELECTRIC COMPANY, St. Louis, Mo., was represented by T. O. Moloney, who explained the merits of the well-known line of transformers made by this company.

DEARBORN DRUG & CHEMICAL WORKS, Chicago, were represented by F. A. Earle, R. W. Francis and George R. Carr. Bottles of perfume extract were distributed.

CROCKER-WHEELER COMPANY, Ampere, N. J., distributed engraved invitations to the delegates to visit its Denver offices. The interests of the company were looked after by W. F. Sullivan, Julian Roe and R. E. Miller.

STANLEY INSTRUMENT COMPANY. Great Barrington, Mass., was represented by F. J. Alderson and F. C. R. Spence, who explained the new rotated jewel-bearing meters for alternating-currents brought out by the company.

THE NATIONAL BATTERY COMPANY, Buffalo, N. Y., had three complete cells connected in series, on exhibition, and various parts of its storage battery. The exhibit was in charge of J. W. Gillette.

THE HIGH-TENSION ELECTRICAL SPECIALTY COMPANY, of Newton, Mass., exhibited one of its high-tension, weather-proof, oil-break switches. These are adapted for 3,000, 4,600 and 6,900-volt systems.

NATIONAL CARBON COMPANY, Cleveland, Ohio, was represented by J. S. Crider, N. C. Cotabish, J. F. Kerlin and C. W. Wilkins. A pocket size electric battery lamp was distributed as a souvenir.

THE SWITCHBOARD EQUIPMENT COMPANY, Pittsburg, Pa., was represented by A. C. Savidge, who exhibited a line of circuit breakers and a protected panel for use on motor circuits.

ELECTRIC APPLIANCE COMPANY, of Chicago, sent its President, W. W. Low, to represent it at the convention. This company was recently compelled to erect a new and larger building to accommodate its rapidly increasing business.

SIMPLEX ELECTRIC HEATING COMPANY, Cambridgeport, Mass., was represented by James I. Ayer and C. W. Richards. The company had an interesting exhibit of heating and cooking appliances, including new treeing irons for shoeshop work and new "Indispensable" water heaters.

LAGONDA MANUFACTURING COMPANY, Springfield, Ohio, had on exhibit a line of boiler cleaners, tube cutters and tube cleaners, resetting machines and damper regulators. A celluloid pocket rule was given as a souvenir. T. P. Molloy was in charge.

PHILADELPHIA ELECTRIC MFG. CO., Philadelphia, Pa., displayed samples of its extensive line of copper hoods and deflectors, incandescent street lighting fixtures, screw glass insulators, arc lamp cut-outs, fuse boxes, service terminals and patented metal wrappers for conduit joints. C. L. Bundy was in charge.

MOBILE ELECTRIC COMPANY, Newark, N. J., was represented by P. E. Ingalls and E. E. Whitehorne. Though but recently in the field as manufacturer of electric signs, the company had a large sign in nightly operation on the building of the Denver Gas & Electric Company opposite the hotel.

THE STANDARD PAINT COMPANY, of New York, distributed an attractive Russia leather mounted desk blotting pad, as well as some of the company's literature. Samples of Rubberoid roofing and its well-known P. & B. specialties were on exhibition. Messrs. Earnshaw and Beckman were in charge.

WESTERN ELECTRIC COMPANY, of New York and Chicago, had a very interesting exhibit consisting of its arc lamps, D. & W. fuses, Thomas high-tension insulators and Brookfield glass insulators. The company's interests were taken care of by E. W. Rockafellow, W. F. Hessel, A. L. Tucker and F. B. Killion.

CENTRAL ELECTRIC COMPANY, Chicago, distributed silver watch fobs with the association insignia $C = \frac{E}{R}$ on one side, and the name of the company and Okonite on the other. The company was represented by George A. McKinlock.

NATIONAL ELECTRIC LAMP COMPANY, of Cleveland, Ohio, was represented by J. R. Crouse, Jr., chairman of the advertising committee, who circulated a very interesting paper on central station advertising methods and the necessity of greater activity in pushing business by central station managers.

THE FORT WAYNE ELECTRIC WORKS, Fort Wayne, Ind., exhibited their new Wood prepayment watt-hour meters, which were fully described in our June number. The exhibit also included a multi-phase switchboard and meters, and was in charge of J. J. Wood, F. S. Hunting and A. A. Serva.

SANGAMO ELECTRICAL MANUFACTURING COMPANY, Springfield, Ill., had a working exhibit of its new types of watt-hour meters for direct current. R. C. Lanphier was in charge of the exhibit. One of the features of the display was an 800-ampere shunt, together with a properly calibrated meter for recording the entire energy of a system.

NATIONAL ELECTRIC COMPANY, Milwaukee, Wis., distributed one of the most acceptable souvenirs at the convention. This consisted of a watch fob made up of a heavy gold plated miniature field ring of the National alternating and direct-current machines, suspended from a heavy silk ribbon. The interests of the company were looked after by C. G. Burton.

THE PHELPS COMPANY, Detroit, Mich., displayed a variety of Hylo lamps, Wynk signs and Wynk transparencies. Skeedoole socket plugs, self-flashing lamps, Turn-up advertising lamps, and a new specialty known as the Skeedoodle A, connected in series with and flashing a number of lamps simultaneously, constituted a feature of this exhibit. W. E. Phelps and J. W. Phelps were in charge.

WAGNER ELECTRIC MFG. CO., of St. Louis, Mo., was represented by V. W. Bergenthal, Geo. B. Foster and G. P. Cole, who accompanied many of the delegates to the store of Gilbert, Wilkes & Co., the company's local representatives, where a large stock of single-phase motors, transformers and instruments was displayed. The company distributed a large number of bulletins at its convention headquarters on the same floor with the convention hall.

HENDRIE & BOLTHOFF MFG. & SUPPLY CO. had three large parlors and a staff of representatives at the convention. This company is the local representative of the National Electric Company, H. W. Johns-Manville Co., Stanley Electric Instrument Company, Stanley-G. I. Electric Mfg. Co., Century Electric Co., John A. Roebling's Sons Co., Electric Controller & Supply Co., Kuhlman Electric Co., and a number of engine and boiler manufacturers.

H. W. JOHNS-MANVILLE CO., of New York, had a very complete exhibit comprising a full line of National Electric Code standard fuses up to 600 amperes; fuse plugs, 1 to 30 amperes and 31 to 60 amperes; double and single brass blocks, and two and three-pole main line blocks. It also displayed a full line of Noark standard fuses, blocks and fuses, front and rear connection contacts, two and three-pole service cut-out boxes, and main-line single and double-branch subway boxes. The exhibit also included a representative line of molded overhead line material, molded mica weather-proof sockets, high tension strain insulators of a working pressure up to and including 5,000 volts. The exhibit was in charge of J. M. Perry and J. W. Hardy.

THE GENERAL ELECTRIC COMPANY had a large parlor adjacent to the convention hall. This was attractively furnished and decorated. The mercury arc rectifier exhibited by the company naturally called forth large interest. As a souvenir the company distributed a neat miniature frosted incandescent lamp mounted as a scarf pin. At Colorado Springs the company had for its headquarters the sun parlor at The Antlers. A list of the G. E. men present follows: General Irving Hale, manager Denver office; G. A. Woolley, supply manager Denver office; H. C. Glaze, sales department; C. P. Mahaffey, engineer, Denver office; J. V. Swanson, construction department, Denver office; Robt. Tait, auditor, Denver office; E. E. Gilbert, lighting department, Schenectady; A. D. Babson, supply manager, New York; M. D. Grosh, Salt Lake City; O. E. Turner, Dallas, Tex.; J. Scribner, lighting department, Chicago; W. F. Smith, Minneapolis; J. H. Livsey, Detroit; P. D. Wagoner, Schenectady; H. W. Hillman, Schenectady; F. G. Vaughn, Schenectady; H. J. Buddy, Philadelphia; F. H. Gale, advertising department, Schenectady; F. W. Wilcox, incandescent lamp department, Harrison, N. J.; C. B. Burleigh, Boston; H. C. Houck, Cincinnati.

WESTINGHOUSE ELECTRIC & MFG. Co. had an exhibit adjoining the convention hall which was unusually attractive. In the center of the room on a pedestal surrounded by palms was a cub bear holding in its right paw a Sawyer-Man incandescent lamp, and suspended immediately over the bear was a large eagle holding in its claws two of the "lumino" lamps of the Sawyer-Man Company. The display proper consisted of a full line of incandescent and arc lamps, lightning arresters, transformers, meters, circuit-breakers, motors, etc. The company had its headquarters in an adjoining room, where refreshments were served and literature descriptive of the company's apparatus distributed. A sign one hundred feet long and extending to within 20 feet of the ground floor was suspended from the roof of the lobby on which was spelled from top to bottom the name of the company. This sign was visible from every point inside the hotel, making a very attractive advertisement. The Nernst Lamp Company had on exhibit a full line of its lamps at the Hotel Savoy, E. R. Roberts being in charge. The representatives of the Westinghouse Company were taken out on a special car and consisted of the following: From the Westinghouse Electric & Manufacturing Company—C. S. Cook, manager of the railway and lighting department; C. B. Humphrey, manager detail and supply department; G. B. Griffin, manager of the same department; H. P. Davis, assistant chief engineer; W. C. Webster, assistant to the second vice-president; T. H. Bailey Whipple, general lamp agent; P. N. Jones, manager Denver district office; C. E. Skinner, Paul McGahan, K. C. Randal and Clarence Renshaw, engineers; S. A. Chase, of the New York sales office; W. R. Pinckard, of the Chicago district office; H. S. Sands, E. C. Means and B. S. Manuel, of the Denver district office. From Sawyer-Man Electric Company, Walter Cary, manager. From the Nernst Lamp Company—Max Harris, sales manager; S. Solomon and Mr. R. D. Marthens, district managers; E. R. Roberts, of the Pittsburg office. The Westinghouse Machine Company was represented by C. C. Chappell, manager of the Denver office. The arrangements were in charge of J. C. McQuiston, superintendent of the publishing department, and L. M. Cargo, the manager of the Denver office of the Westinghouse Electric & Manufacturing Company.

ALLIS-CHALMERS COMPANY was well represented at the convention by the following eleven officials: O. A. Stranahan, manager power department, Milwaukee; M. C. Miller, executive department, Milwaukee; C. A. Tupper, publicity department, Milwaukee; J. R. Jeffrey, assistant secretary Bullock Electric Manufacturing Company, Cincinnati, Ohio; David Hall, assistant chief electrical engineer, Cincinnati; Louis E. Bogen, engeer electrical department, Cincinati; George H. Berg, district office manager, Boston; George B. Foster, district office manager, Chicago; R. B. McConney, district office manager, Denver; H. L. Woolfenden, electrical department, Denver; R. J. Glendenning, assistant district office manager, Salt Lake, Utah. A large reception room was elaborately furnished and the walls hung with framed pictures representing Bullock electrical apparatus and leading installations. The bulletins elaborating on these themes covered two large tables. The new binders of the company, which are arranged so as to permit the bulletins inserted to lie perfectly flat when the binder is open, attracted much attention. Guests were taken from the door of the hotel in conveyances to the plant of the Denver Gas & Electric Company, where Allis-Chalmers engines and the following Bullock apparatus are installed: Two 1500-kw., three-phase, 60-cycle, direct-connected Bullock alternators; four 600-kw., three-phase Bullock belted alternators; two 400-kw. Bullock direct-current belted generators. This plant is the largest between the Missouri River and the Pacific Coast, and is a model of its kind.

Other companies not exhibiting but represented were as follows: Atlantic Insulated Wire & Cable Company, New York, George F. Porter, sales manager. Ko Sign Company, Denver, Charles F. Heywood, manager. American Steel & Wire Company, Chicago, H. J. Woelke, E. R. Poole, W. E. Benedict, Denver. Benjamin Electric Manufacturing Company Chicago, R. B. Benjamin, manager. John A. Roebling's Sons Co., E. B. Bartlett, Chicago. Pawling & Harnischfeger, Milwaukee, W. E. Kreamer. Electric Storage Battery Company, G. H. Atkin, Chicago manager, and T. B. Entz, St. Louis. De La Vergne Machine Company, New York, C. E. Lucke. Arnold Company, Chicago, W. Arnold. American Circular Loom Company, Chelsea, Mass., Thomas G. Grier, Western manager, Chicago. New York & Ohio Company, Warren, Ohio, W. D. Packard, manager. Western Chemical Manufacturing Company, Denver, L. B. Skinner. Electrical Testing Laboratories, New York, W. S. Howell, manager. Phoenix Glass Company, New York, A. H. Patterson, vice-president and manager; E. H. Fox, Chicago. Okonite Company, New York, George T. Manson, superintendent. Baker & Co., Inc., New York City, C. O. Baker, president. Chase-Shawmut Company, Newburyport, Mass., George A. Gray, India Rubber & Gutta Percha Insulating Company, New York, J. B. Olson, manager sales department. Western Lumber & Pole Company, Denver, B. F. Vreeland, president. American District Steam Company, Lockport, N. Y., C. R. Bishop, secretary and manager; H. C. Eddy, Western manager, Chicago. Chicago Fuse Wire & Manufacturing Company, Chicago, W. W. Merrill, manager. Otis Elevator Company, J. F. Elam, Denver. Bryan-Marsh Company, S. E. Doane, Cleveland; L. E. Mason, Denver. Standard Underground Cable Company, Pittsburg, J. R. Wiley, manager Chicago office, E. J. Pietzcker, Southwestern manager, St. Louis. Pass & Seymour, Solvay, N. Y., John W. Brooks, manager; J. S. Jackson, Chicago. Stanley-G. I. Electric Manufacturing Company, Pittsfield, Mass., Martin J. Insull, third vice-president; Thomas F. Clohesey, sales manager, St. Louis. Capital Electric Co., Denver, A. R. Hall, president. Jeffrey Manufacturing Company, Columbus, Ohio, F. R. Field, Western sales manager. Flint Lomax Manufacturing Company, Denver, F. W. Lomax, manager.

OBITUARY.

C. H. WELLMAN and T. R. MORGAN, both of the Wellman-Seaver-Morgan Company, were killed by the wreck of the Twentieth Century Limited train, June 21, at Mentor, Ohio.

WILLIAM W. DONALDSON, the well-known engineer of the Gould Storage Battery Company, died at Elk Ridge, Md., June 12, aged 42 years. Mr. Donaldson received his education at the well-known Carey School, Baltimore, and Princeton University. He engaged in storage battery work in 1884 and was connected successively with the Storage Battery Company, of Baltimore, the Eastern Electric Company, the Donaldson-Macree Storage Battery Company and the Gould Storage Battery Company.

FRANKLIN LEONARD WAINWRIGHT POPE, son of the late Franklin L. Pope, and nephew of Ralph W. Pope, secretary of the American Institute of Electrical Engineers, died at Cornwall, N. Y., May 27. Mr. Pope was born in Elizabeth, N. J., in 1880, and graduated from Amherst College in 1903. He was on the staff of the Assistant Signal Engineers of the Pennsylvania Railroad, but failing health compelled him to resign in September, 1904. He spent the winter at Saranac Lake, but the change was not beneficial. He was greatly interested in railroad work, and gave every promise of a brilliant future.

E. A. LESLIE, general manager of the Kings County Electric Light & Power Company, Brooklyn, N. Y., died on June 5 from pneumonia. Mr. Leslie was one of the large number of telegraphers who graduated from that branch of electrical work into electric light and power work in the eighties. He entered the telegraph service as a messenger boy and worked up through the various grades to the superintendency of the Mutual Union Telegraph Company, with headquarters at Washington, D. C., in 1882. In 1884 he was appointed superintendent of the National Telegraph Company, which was part of the Baltimore & Ohio system, and in 1885 he was made general superintendent of the Eastern Division with headquarters in New York. In 1888 he accepted the management of the Manhattan Electric Light Company's affairs. This company was afterward consolidated with the Edison Electric Company, with which he remained until 1901, when he became general manager of the Kings County Company. Mr. Leslie was born in Harrisburg, Pa., in 1849. He leaves a widow and two children.

PERSONAL.

MR. CHAS. S. DAVIS, for the past six years master electrician of the Bureau of Construction and Repair, Charlestown Navy Yard, has joined the engineering staff of the Holtzer-Cabot Electric Company, Boston, Mass.

MR. EUGENE LENTILHON, for several years past a contracting engineer in New York, has joined the forces of J. G. White & Company, Inc., and is now on his way to Chili on an important engineering mission.

MR. ALFRED WATERS PROCTOR has joined the staff of Rosenbaum & Stockbridge, the well-known New York patent attorneys. Mr. Proctor is an electrical engineer, and for the past seven years has been an examiner in the United States Patent Office.

MESSRS. EDWARD S. BEACH and CHARLES McC. CHAPIN have formed a partnership under the style of Beach & Chapman and have engaged in the practice of patent, trademark and copyright law. The new firm has established offices at 60 Wall Street, New York, and 53 State Street, Boston.

MR. W. W. FREEMAN has been appointed vice-president and general manager of the Kings County Electric Light & Power and the Edison Electric Illuminating Companies, of Brooklyn, to succeed the late E. A. Leslie, whose death is noted elsewhere. Mr. Freeman has risen step by step from the position of stenographer to the general manager in 1889 to his present responsible post.

Mr. HAROLD ULMER WALLACE has accepted the position of third vice-president of J. G. White & Company, Inc., resigning the position of chief engineer of the Illinois Central Railroad in order to affiliate with the White organization. Mr. Wallace will have charge of the company's construction department, and his headquarters will be at the main office in New York.

MR. W. S. HEGER, whose name has been closely associated for years with the Westinghouse interests, has joined the Allis-Chalmers Company, becoming assistant to the vice-president and general manager.

Born in 1857 at Fort Simcoe, Washington Territory, then one of the frontier posts of the United States Army, Mr. Heger received his education both in this country and Europe, spending seven years in Vienna, Austria. After receiving the degree of M.E. at Stevens Institute of Technology in 1879, Mr. Heger's business career began in the mechanical draughting room of the Edge Moor Iron Works. Shortly after this time the Edge Moor Iron Works took the contract for the construction of the Brooklyn Bridge. Mr. Heger was placed in charge of putting this work through the draughting room, through the shops and through the testing and inspection departments.

In 1885 Mr. Heger went into business upon his own account as a contractor and electrical engineer and later became sales agent and constructor for the Edison Company for isolated lighting in the states of Delaware, Maryland, the Virginias and the Carolinas. In 1889 Mr. Heger was sent to San Francisco as district manager for the Pacific Coast territory for the Edison Company and for the Edison United Manufacturing Company.

W. S. HEGER.

He built up the organization there which exists today under the General Electric Company, and established a large and successful business.

Owing to the serious illness of a daughter Mr. Heger gave up all business in the fall of 1890 and remained in retirement for two years. Resuming active work in 1902 he accepted the place of general manager of the Wilmington City Railway Company, Wilmington, Delaware, and spent three years there rebuilding and operating the road. Returning to the Pacific Coast again in 1895, Mr. Heger became the district manager for the Westinghouse Electric & Mfg. Company, with headquarters in San Francisco. He built up a strong selling organization and made a wide market for the products of his own company and those of the Sawyer-Man Company. At the beginning his territory covered the whole coast country from Alaska to Old Mexico, and reached east as far as Salt Lake City. As business was developed the territory was divided and district offices were opened at Seattle, Salt Lake City, Los Angeles and in British Columbia. Mr. Heger's work was marked particularly by his success in inventing methods to promote and secure sales in sparsely settled districts, and in securing the co-operation of affiliated lines of business.

During Mr. Heger's administration the initial long distance power transmission plants of the Pacific Coast were built, and in the construction of these many unlooked-for features had to met. The creating of a market for the products of his company in the new fields developed by these long distance transmission plants formed a valuable part of his experience.

Mr. Heger resigned his position with the Westinghouse Company in April. His headquarters are at the general offices of the Allis-Chalmers Company in Milwaukee.

TRADE PUBLICATIONS.

SWITCHBOARDS. The Switchboard Equipment Company, Pittsburg, Pa.—Bulletins Nos. 2 and 3, devoted to circuit-breakers and motor control panels.

TWO-PLATE STORAGE BATTERY. The Electric Storage Battery Company, Philadelphia, Pa.—Bulletin No. 92, in which is described and illustrated the two-plate Chloride cell.

AN ELECTRIFIED RAILWAY SHOP. Crocker-Wheeler Company, Ampere, N. J.—This is bulletin No. 58, containing an illustrated description of the motor equipment of the Pittsburg & Lake Erie Railroad shops.

THE IDEAL ENGINE. A. L. Ide & Sons, Springfield, Ill.—A vest-pocket pamphlet handsomely executed and containing a well-illustrated argument in favor of the Ideal automatic engine for electric light and power service.

WATER-TUBE BOILERS. Parker Boiler Company, Philadelphia, Pa.—This is the 1905 catalogue of this company and contains an illustrated description of its well-known water-tube boiler, with and without superheater attachment

VARIABLE-SPEED MOTORS. The Electro-Dynamic Company, Bayonne, N. J.—Circulars Nos. 13 and 14, the one devoted to individual motor-drive and the other to a description of the "Interpole" variable-speed motor.

STEAM SPECIALTIES. The Loew Supply & Manufacturing Company, Cleveland, O.—A handsome catalogue of octavo size devoted to Loew grease and oil separators, feed-water heaters, steam separators, exhaust heads, condensers, etc.

MERCURY ARC RECTIFIER. General Electric Company.—This is bulletin No. 4411, containing an illustrated description of the G. E. mercury vapor tube and accessories for obtaining direct current from an alternating-current circuit.

WATER - WHEEL GOVERNORS. Replogle Governor Works, Akron, O.—This is a catalogue of standard size devoted to the new Replogle water-wheel governor, which was described in connection with the water-wheel article in our January number.

EMPLOYERS' LIABILITY. The Consolidated Engine Stop Company, New York.—This is a folder containing extracts from the opinion rendered by the Court in a recent damage suit on which occasion favorable comment was made of the Monarch engine stop.

OIL SWITCHES AND CIRCUIT-BREAKERS. Hartman Circuit-Breaker Company, Mansfield, O. —Bulletin No. 6, devoted to the well-known Hartman switches and circuit-breakers, representative types of which were recently described in this paper.

LIFTING MAGNETS. The Electric Controller & Supply Company, Cleveland, O.—This is a handsomely executed catalogue of standard size, containing illustrations of electromagnets for lifting pig iron, sheet and wire scrap, large castings, etc.

STEAM CONDENSING APPARATUS. W. H. Blake Steam Pump Company, Hyde Park, Mass.—This is catalogue No. 25, containing illustrations and brief descriptions of the Blake horizontal air pump and jet condenser, witn vertical air pump and jet condenser, and surface condenser with air and circulating pump.

ORE AND COAL-HANDLING MACHINERY. The Wellman-Seaver-Morgan Company, Cleveland, O.—This is a magnificent publication of octavo size, profusely illustrated and handsomely executed. As its title indicates, it is devoted to machinery of all types for handling coal and ores.

OIL-INSULATED TRANSFORMERS. Stanley-G. I. Electric Manufacturing Company, Pittsfield, Mass.—This is bulletin No. 145, containing an illustrated description of the "Type B. O." oil-insulated transformers for lighting service. These are built in all of the standard voltages, of course, and are of the shell type.

ELECTRIC LIGHT SPECIALTIES. The Tea Tray Company, Newark, N. J.—Catalogue No. 15, of convenient pocket size, devoted to lighting specialties such as incandescent lamp hoods, street fixtures for incandescent lamps, goose-neck brackets and flanges, weatherproof sockets, shades and reflectors for indoor lamps, etc.

BELTED ROTATING FIELD ALTERNATORS. Westinghouse Electric & Manufacturing Company.—This is circular No. 1113, containing an illustrated description of a very compact type of revolving-field alternator. The bearings of the machine are mounted in circular brackets similar to those of the familiar self-contained induction motor.

MAP OF THE N. Y. SUBWAY SYSTEM. New York Central & Hudson River Railroad.—This is No. 39 of the Four-Track Series, and consists of a very clear, well-executed map of the subway and elevated railway systems on Manhattan Island and in the Bronx, showing the connections between the railway systems and the New York Central Railroad.

THE CARE OF INSULATING COMPOUNDS. Sterling Varnish Company, Pittsburg, Pa.—An extremely valuable and instructive book of pocket-size, containing much practical information relating to the application, testing and care of insulating compounds and varnshes. The contents of the book are devoted chiefly to Sterling compounds, of course, but it is nevertheless valuable to users and repairers of electrical machinery.

BUSINESS NEWS.

TIPLESS LAMP COMPANY, New York, has removed its general offices and show rooms to 256 West 23d street.

MANUFACTURERS AGENTS' ASSOCIATION, Los Angeles, Cal., has removed its main offices from 308 South Los Angeles Street to 641 Huntington Building.

WESTERN ELECTRIC COMPANY, Chicago and New York, reports a brisk trade in Sunbeam incandescent lamps, the sales being unusually large for this season of the year.

THE NEW YORK COIL COMPANY, New York, recently filled an order for induction coils to equip six wireless telegraph stations in South America.

PITTSBURG GAGE & SUPPLY COMPANY, Pittsburg, Pa., reports a large number of recent sales of "White Star" oil filters, many of which were for electric light and power service.

CRANE COMPANY, Chicago, has removed its general offices and sales department from 10 North Jefferson Street to its new office building at 519 South Canal Street.

STANLEY INSTRUMENT COMPANY, Great Barrington, Mass., announces that it is now prepared to fill all orders for model H-6 jewel-bearing wattmeters, which are of the induction type.

THE LOCKE INSULATOR MANUFACTURING COMPANY, Victor, N. Y., has started still another addition to its factory since the one recently noted. The new addition will cover a ground space 40 feet by 100 feet, and will be devoted exclusively to the process of cementing together the parts of the multi-part porcelain insulators.

AITON MACHINE COMPANY, New York, has been incorporated under the laws of New Jersey for the manufacture and sale of machinery covered by the patents of Thomas A. Aiton relating to wire insulating, cabling and rubber manipulating machinery. The company's manufacturing operations will be carried on in conjunction with the work of the Marine Engine & Machine Company, Harrison, N. J.

ALLIS-CHALMERS COMPANY, Chicago, reports among a large number of recent sales one to the Twin City Rapid Transit Company, Minneapolis, of a vertical, cross-compound Reynolds-Corliss condensing engine to be direct-connected to a 3500-kw., three-phase alternator. This is the fourth engine of this size and type ordered from the Allis-Chalmers Company by the Twin City Company.

CENTURY ELECTRIC COMPANY, St. Louis, Mo., reports that its single-phase, alternating-current motors are steadily increasing in popularity as the trade becomes familiar with the inherent features of the machine. During the month of May alone the company's sales of single-phase, self-starting motors exceeded its entire sales for the year of 1904. These machines are built in sizes ranging from ½ to 5 horse-power, for 60 cycles and other commercial frequencies.

THE C. & C. ELECTRIC COMPANY, Garwood, N. J., reports having taken a number of orders recently for direct-connected motors for driving machine tools. Among others is one from the Pittsburg office for some twenty motors, nearly all of which are of the variable speed type.

G. M. GEST, of New York and Cincinnati, has just been awarded the contract for the construction of a complete underground conduit system for the Montreal Light, Heat & Power Company, Montreal, Canada. Over 1,000,000 feet of conduit are to be used in the construction.

INGERSOLL-RAND COMPANY is the title of a new corporation which is an amalgamation of the Ingersoll-Sergeant Drill Company and the Rand Drill Company. The new organization has been incorporated under the laws of New Jersey, with a capitalization of $10,000,000. The factories are located at New York, Painted Post, N. Y., Ossining, N. Y.; Tarrytown, N. Y.; Phillipsburg, N. J.; Easton, Pa., and Sherbrooke, Quebec. The main offices of the new company will be located for the present at 26 Cortlandt Street, New York.

THE PEERLESS ELECTRIC COMPANY, Warren, Ohio, is unusually busy at this season, finding it necessary to operate the factory day and night, and reports a fine lot of orders booked. In the fan-motor department, the output on regular lines is largely increased, and the new type of oscillating fan is being well received by the trade. A special high voltage testing transformer has just been furnished to the Jefferson Physical Laboratory of Harvard University, a duplicate of the transformer recently supplied to the laboratory of Johns Hopkins University. Contracts on hand ensure weeks of steady operation in the motor department, and new machinery is being added to care for the growth of this branch of the business. Among large jobs just installed are the complete equipment with individual motors of the extensive planing mills of the Warren Manufacturing Company and the Western Reserve Lumber Company, both at Warren.

THE WESTINGHOUSE ELECTRIC & MFG. COMPANY has just closed a contract for the equipment of the main generating station and four rotary converter sub-stations of the Cincinnati Northern Traction Company. The power house will be located at Hamilton, Ohio, and the original installation will be of 5,000 kilowatts capacity, with provisions for ultimately increasing it to 10,000 kilowatts. In the generating station will be located three 1500-kw. and one 500-kw. three-phase, turbine-type generators, and three 300-kw. rotary converters. Current will be generated at 375 volts to avoid the necessity of lowering transformers for the main station rotaries. The outgoing lines will be required with raising transformers having a ratio of 375 to 33,000 volts. Each generator will be driven by a Westinghouse-Parsons steam turbine and excited by a direct-current generator attached to the end of the turbine shaft. Each sub-station will contain a 300-kw. rotary converter supplied by three 33,000 to 375-volt step-down transformers. All transformers are of the oil-insulated, self-cooling type. Besides the above, the contract includes all necessary switchboards and protective devices for the control and protection of apparatus in the power house and rotary stations.

CENTRAL STATION NEWS

Readers are cordially invited to contribute to this department items of news relating to plants in their vicinity.

ALABAMA.

ENSLEY.—The Mayor and Board of Aldermen are stated to have authorized the Lighting Committee to investigate the question of constructing an electric light plant, procure plans and specifications and report back to Council July 6.

GADSDEN.—Plans are on foot for the building of a power plant on Little River, near Gadsden, to cost between $1,000,000 and $1,500,000, to furnish power to many nearby towns and cities. H. T. Henderson and brother, of Durango, Col., are interested.

TALLADEGA.—Power has been turned on from the new plant at the shoals on Chocolocco Creek. The city will, in the future, be lighted from this plant, and power furnished manufactories. Engineers estimate that 5000 horse-power is available from this point.

FLORENCE.—Articles of incorporation of the Mussel Shoals Power Company have been filed with the office of the Probate Judge of Colbert County, at Tuscumbia. The officers of the company are Thomas H. Jackson, of Memphis, president; James Jackson, of Tuscumbia, vice-president, and John H. Harris, of Courtland, secretary and treasurer.

ARIZONA.

WINSLOW.—At a recent special election the people voted in favor of granting a franchise for electric light and power purposes to the Winslow Electric Light & Power Company.

PRESCOTT.—The Arizona Power Company has been organized for the purpose of supplying electrical power within the bounds of Yavapai County, commercially, and at a cost that will make it an inducement for mines or any other business institution that will require power to use its product. The company now has privileges for the development of power on Fossil Creek, about 25 miles east of Mayer.

ARKANSAS.

PRAIRIE GROVE.—An electric light plant is soon to be established in this city.

FORT SMITH.—Bonds have been sold to the amount of $17,000 for the purpose of installing an electric light plant in Durdanelle.

WARREN.—The Warren Light & Water Company is reported incorporated with a capital of $12,000, to construct an electric light and power plant. Fred. L. Purcell, president; Carl Hollis, secretary.

ROGERS.—The Rogers Light & Water Company, of this city, has been incorporated with a capital stock of $100,000. Officers are W. R. Felker, president; F. F. Freedman, vice-president; J. E. Felker, secretary and treasurer.

CALIFORNIA.

WHITTIER.—The Edison Electric Company will double the capacity of its plant.

TRUCKEE.—The plant of the Truckee Electric Light & Power Company is reported to have been destroyed by fire.

SEBASTOPOL.—The Sebastopol Light, Power & Water Company has secured the franchise for the electric light and power plant.

SANTA ANA.—It is stated that bids will be received until July 3 by Edward Telford, City Clerk, for $57,000 electric light and power bonds.

SIERRAVILLE.—The Sierra Valley Light & Power Company has begun digging a big ditch which will connect with the flume feeding its power plant. The ditch will be two miles long.

VENTURA.—C. E. Moore, of Santa Clara, is reported to have been selected to prepare plans and estimates for water works and an electric light plant for Ventura.

IONE.—The Ione Electric Light & Power Company is reported incorporated, with a capital of $30,000, by Chas. Erickson, John Hancock and others.

FORT BRAGG.—It is reported that the Fort Bragg Electric Light Company, Inc., has applied for a franchise to construct and operate an electric plant for generating electricity to furnish heat, light and power for this city.

UKIAH.—It is reported that a franchise has been applied for by A. Brown for the right of way, erection of poles, etc., for the transmission of electricity for power, etc., over roads between Elk and Gualala, and bids for said franchise will be received until July 3.

FRESNO.—The San Joaquin Light & Power Company is reported incorporated with a capital of $3,000,000, by H. W. O'Melveny, of Los Angeles; Abraham Haas, of San Francisco, and others. It has taken over the plant of the San Joaquin Power Company at Fresno and proposes developing the water power of San Joaquin River and supplying Fresno and surrounding territory with light and power.

SAN FRANCISCO, CAL.—President H. L. Shannon says that the Shasta Power Company has a force of 75 men at work at its power site, near Bear Creek Falls, Shasta County, 24 miles east of Redding. All materials will be delivered promptly, and it is expected that the first unit of 1500 horse-power will be installed in September next. The plant is in the center of the great copper belt mining and smelting region.

SAN FRANCISCO.—The Washoe Power & Development Company's water power electric plant, located ten miles east of Reno, Nev., is in operation, transmitting to Reno and to Sparks, 12 miles. A distributing system has been installed for light and power purposes. The initial installation includes a Stanley 750 kw., three-phase generator, direct connected to a water wheel. Specifications have been issued for an additional 750-kw., three-phase generator for the same plant.

SAN FRANCISCO.—Sidney Sprout, general manager of the Culiacan Electric Company, a San Francisco corporation, has returned from Culiacan, Mexico, where he was making arrangements for the installation of the first unit of the new lighting plant. This will carry the street lighting, for which a contract has been closed. Babcock & Wilcox boilers, and Ideal engine and a General Electric 100-kw., three-phase generator will be shipped within a few weeks by steamer from San Francisco, and the entire system will be in operation by September 1. Negotiations have been in progress for the purchase of the small electric plant now in operation on commercial lighting.

SAN FRANCISCO.—At a special meeting of the stockholders of the Battle Creek Power Company, held June 5, it was voted to authorize an issue of 30-year bonds amounting to $1,000,000 for the purpose of carrying out the project of constructing an electric power transmission in Butte County, Cal. The company's complete plans are not ready for publication, but it is understood that the gold-dredging districts, including Oroville, are expected to furnish a market for a part of the electric power to be developed by a modern hydro-electric plant. Dudley C. Bates is secretary of the company. Several electric railways which are projected in the same territory may be purchasers of power in time.

SAN FRANCISCO.—The Oceanside Electric Light Company, which has been incorporated with a capital stock of $20,000 by R. H. Fitzgerald, J. T. Boyd, H. B. Young, J. H. Brenner and J. D. McGown, will erect an electric generating plant near the ocean beach in San Francisco. It is said that many contracts have been signed for lighting current for terms of three years at 10 cents per kw.-hour. R. H. Fitzgerald is president of the

company; J. H. Brenner, secretary, and J. T. Boyd, general manager. The ocean beach district extending several miles south of the Cliff House, is building up rapidly, and the nearest lighting plant is six miles distant. It is said that Los Angeles capital is behind the new enterprise.

COLORADO.

DENVER.—It is proposed to build a subway on, probably, Sixteenth Street, in this city, and place the overhead wires therein.

NEW CASTLE.—The Henry Electrical Corporation, of Denver, has purchased the Peter Kinney electric light plant of this city and is overhauling the plant and remodeling it along more improved lines. New machinery throughout will be installed.

CONNECTICUT.

SHARON.—The Sharon Electric Light Company has received permission to operate in Canaan and North Canaan.

WALLINGFORD.—A resolution has been offered for the purpose of extending and enlarging the electric plant of the borough and utilizing the water power of the Quinnipiac River in the manufacture of electricity.

HARTFORD.—The Committee on Incorporations reported favorably on the resolution incorporating the Northern Connecticut Power Corporation. This corporation will acquire the water privileges in New Hartford known as the Greenwood water power.

NORWICH.—The committee on incorporation of the Legislature has reported favorably the petition for a charter for the Uncas Power Company, of Norwich. The charter gives the company the right to manufacture and distribute electricity in the towns of Bozrah, Colchester, East Lyme, Franklin, Griswold, Groton, Lebanon, Ledyard, Lisbon, Lyme, Montville, North Stonington Old Lyme, Preston, Salem, Sprague, Stonington, Voluntown and Waterford, and in Norwich and New London in quantities of not less than 25 horse-power to any single customer. The promoters are G. O. Jackson, E. W. Higgins and Charles W. Comstock.

NORWICH.—At a recent meeting of the City Council it was voted to give to the Gas and Electric Commissioners the sum of $60,000, to be expended on repairs to the old plant and to make extensions for new business. The commissioners intend to build a new water gas plant, a new condenser plant, including scrubbers, exhausters, tar and ammonia extractors, and new purifiers. About two miles of new mains will be laid. For the electric plant there will be a new 24-kw. unit direct connected, and a new stack. The city will also have 80 additional incandescent street lights of 25 candle-power for the new district called East Norwich. Extensive repairs will be made on the lines.

DELAWARE.

WILMINGTON.—Mayor Bird has suggested to the Water Commissioners the advisability of constructing an electric light plant to light the reservoirs and park lands and eventually for lighting the city.

WYOMING.—Alex. Daly, representing Philadelphia capitalists, is reported to have presented to the citizens of Wyoming and Camden a proposition to install a water and light plant to supply both towns.

DISTRICT OF COLUMBIA.

WASHINGTON.—The Potomac Electric Power Company has secured the contract for arc lights in certain public parks at $85 per light per year, or a total of $5525.

FLORIDA.

ST. AUGUSTINE.—Gen. Foster is reported to have petitioned Council for a franchise for an electric light plant.

TARPON SPRINGS.—L. R. Fernald, City Clerk, writes that it is proposed to construct an electric light plant and ice factory, at a cost of $6000.

OCALA.—The Florida Power Company is reported incorporated with a capital of $300,000 by W. N. Camp, R. F. Brewer, G. D. Munsing and others.

ST. AUGUSTINE.—J. D. Lawrence, of Jacksonville, is reported interested in the construction of an electric light plant and street railway in St. Augustine.

MONTICELLO.—The Monticello Power Company has been incorporated with a capital of $10,000, to own and operate an electric light and power plant. Incorporators: John M. Henry, John M. Hay, Jr., and S. M. Coat.

GEORGIA.

TALLAPOOSA.—The citizens are reported to have voted to grant Gelder & Black a franchise for an electric light plant.

FORT VALLEY.—Bond to the amount of $12,000 are reported sold, to be used for the construction of an electric light plant.

MONTICELLO.—The citizens are reported to have voted to issue $30,000 bonds for an electric light plant, water works and sewerage system.

MENLO.—The proposed power plant to be constructed near Menlo will cost $150,000. A. J. Lawrence, of Chelsea, Ga., is interested.

SAVANNAH.—A $50,000 subway has been completed in Savannah by the Savannah Electric Company, the Atlantic Coast Line and the city.

SAVANNAH.—The Savannah Lighting Company is in the field for the franchise for municipal lighting against the Savannah Electric Company, which now has possession of the field and franchise.

COLUMBUS.—Press reports state that the Westinghouse Electric & Manufacturing Company, of New York, N. Y., is preparing plans, specifications and estimates for the construction and equipment of the Chattahoochie electric plant for Stone & Webster, of Boston, Mass.

CARTERSVILLE.—The Etowah Power Company, of Gainesville, is reported to have purchased the property of the Etowah Development Company, with privilege to develop and control the water power of Etowah River. It is stated that a survey of the property will be made at once. Engineer, W. A. Carlisle, of Gainesville.

IDAHO.

RATHDRUM.—Nixon & Kimmel have been granted a franchise and will put in a lighting system, under the name of Rathdrum Electric Lighting Company.

COVE.—The power plant being installed in this city is nearly completed and is expected to be furnishing energy for electric lights in the Grande Ronde country by July 1.

HAILEY.—The Cramer Electric Company is stated to have decided to purchase the plant of the Idaho Electric Supply Company, and will furnish light for Hailey and Bellevue. A new plant will probably be installed.

ILLINOIS.

NOKAMIS.—The Henry Electric Light & Power Company, of Nokomis, is reported incorporated with a capital of $20,000 by John H. Crickenberger, Fred. W. Potter and Chas. A. Onyum.

STREATOR.—The Council is reported to have appropriated $30,000 for the establishment of a municipal lighting plant.

PANA.—The Pana Gas & Electric Company is reported incorporated, by T. F. Russell, Wm. Pierce and others, to manufacture electricity for light, heat and power.

PANA.—The National Power, Light & Heating Company is reported organized, with J. N. C. Shumway, of Taylorville, president, and Geo. B. Martin, of New York, N. Y., secretary.

MACOMB.—The Macomb Electric Light & Gas Company is installing new machinery and expects shortly to give all day and night service. The power and lighting circuits are three-phase, 60-cycle alternating current. W. I. Savidge is the electrical contractor.

BUSHNELL.—The City Council has granted a ten-year extension of franchise to the Bushnell Electric Light & Power Company, with a provision that certain additional equipment be added to the present plant within 90 days after July 1. Two 175 horse-power boilers, two 175 horse-power engines and generators, and auxiliary equipment will be purchased by the company at once.

INDIANA.

CRAWFORDSVILLE.—The Water & Light Company is reported to have decided to expend about $125,000 in improvements.

CONNERSVILLE.—It is reported that the Connersville Light, Heat & Power Company will expend about $25,000 in improvements.

CAYUGA.—The Town Board is reported to have ordered plans and will soon let contracts for constructing an electric light plant.

GREENFIELD.—The Water and Light Commissioners are reported to be in the market for a 350-h.p. engine and two new boilers for the electric light plant.

MONTPELIER.—The Montpelier Light & Water Company has been incorporated, with a capital of $75,000. The directors are T. J. Driscoll, P. C. Connors and others.

WASHINGTON.—The Town Trustees contemplate installing 150 enclosed arc lights to take the place of the open lights now in use. M. A. Roberts is superintendent.

FRANKFORT.—The Indiana Hydraulic Company is reported organized, with Eugene Rush, president, and N. W. Hanna, secretary, both of Frankfort. The company will be incorporated with a capital of $2,000,000 and will manufacture electricity. It will get its power from Wildcat Creek. A dam 30 ft. high and 368 ft. long, of solid cement, will be constructed.

ANDERSON.—A number of farmers living within a radius of six miles have petitioned the City Council to be connected with the municipal electric light plant. The city authorities look favorably on the request. The electric light plant has been enlarged and has a surplus of power which can be utilized in this way. The farmers have agreed to furnish the poles.

MONTICELLO.—The Tippecanoe Hydraulic Company is reported organized to utilize the water power of Tippecanoe River; capital, $800,000. It is proposed to construct four power plants, one at Norway, another at Tioga, another at Oakdale and the fourth at Springboro. Work is about to begin on the plant at Norway, which will cost about $195,000. The company proposes furnishing power to Lafayette, Logansport and Frankfort. A. A. McKain, of Indianapolis, and C. D. Meeker and D. W. Thompson, Jr., of Frankfort, are reported interested.

INDIAN TERRITORY.

WYNNEWOOD.—J. H. Boozer, City Recorder, writes that it is proposed to vote on issuing bonds for the construction of water works and an electric light plant, but nothing definite has been done, except to appoint a committee to figure cost, etc.

IOWA.

WAUKON.—The electric light company proposes to construct a concrete dam 200 ft. long and 20 ft. high.

ALDEN.—T. R. Holmes, City Clerk, writes that it was voted to grant an electric light franchise to the Paterson Heat, Light & Water Co.

OSCEOLA.—The Osceola Electric Light Company has been incorporated by the Osceola Light, Heat & Power Company.

CLARINDA.—Plans for remodeling and enlarging the building of the Lee Electric Light Company have been made.

SUMNER.—L. L. Stewart, of Omaha, is reported to have secured a franchise for an electric light plant.

VALLEY JUNCTION.—The Valley Junction Water & Light Company has been incorporated with a capital of $12,000. John Fisher is one of the incorporators.

COUNCIL BLUFFS.—Creston will have a new electric company. The organization was launched with an authorized capital of $50,000. Incorporators: J. C. Sullivan, John Hackett and others.

FORT DODGE.—The City Council is reported to have appointed a committee to investigate the construction of a gas and electric light plant, to be owned and operated by the city.

CRESTON.—The City Clerk writes that a franchise to run an electric light plant has been granted

to a new company, with J. C. Sullivan, president, and J. W. Reynolds, secretary. The company is now arranging to purchase equipment for a plant to cost about $40,000.

KANSAS.

WINFIELD.—The citizens have voted to issue $15,000 bonds to complete the electric light plant.

CHETOPA.—A. R. Bell, City Clerk, writes that the proposed water works and electric light plant will cost $29,500.

FRONTENAC.—The Crawford County Light & Water Company has secured a franchise for an electric light plant. H. G. Whiteleather is city clerk.

TOPEKA.—The Citizens' Light, Heat & Power Company is reported incorporated with a capital of $300,000 by J. J. Heim, of Kansas City; Arnold Kalman, of St. Paul, Minn.; Jas. L. Wolcott, of Dover, Del., and others.

LAWRENCE.—The Lawrence Electric Light Company has been reorganized, with Irving Hill as president and R. C. Johnston as secretary and manager. The company proposes to purchase new engines and dynamos and to enlarge the plant to three times its present capacity.

KENTUCKY.

PADUCAH.—The Paducah Gas & Electric Company has been sold to James C. Utterback. The price paid is stated to be $135,000.

GRAYSON.—Claude Wilson, of Olive Hill, has secured a franchise for an electric light plant and telephone system. The total cost of work will be about $25,000.

MORGANFIELD.—T. W. Gilbert, of Chicago, has purchased the electric light plant for $6,000. The new owner proposes to install a 3,000-light generator and a 200-h.p. engine.

PADUCAH.—Plans, specifications and estimates on contracts for the complete electrical construction and equipment for the new Paducah electric light and power plant to be built by St. Louis and New York capitalists are being prepared.

CAMPBELLSVILLE.—J. L. Atkinson, president Campbellsville Lighting Company, writes that bids for constructing an electric light plant to cost about $4000 will be received about Aug. 15. Engineer, B. S. Kincort, Lebanon, Ky.

GEORGETOWN. — The Georgetown Water, Gas, Electric Light & Power Company is reported reorganized, and will add a steam-heating plant and a new gas plant. F. X. Long, Newport, and S. L. Allen, Georgetown, are among the incorporators.

LOUISIANA.

ROBELINE.—A new electric plant will be established in this city soon.

NEW ORLEANS.—R. S. Stearns writes that the Algiers Railway & Lighting Company is to construct a power plant at a cost of $200,000.

BATON ROUGE.—It is reported that the Baton Rouge Gas & Electric Company will double the capacity of its plant.

NEW ORLEANS.—The Consumers' Electric Light Company has secured a site for its plant and will at once begin the erection of a first-class and completely equipped building.

BATON ROUGE.—The Baton Rouge Electric & Gas Company has acquired the Capital Light & Power Company. Mr. C. H. Kretz has become general manager.

SHREVEPORT.—W. R. Thomas, city secretary, writes that an election will be held in August to vote on issuing $150,000 bonds for the construction of a municipal electric light plant.

ABBEVILLE.—Bids will be received by the Board of Aldermen (Geo. W. Summers, secretary) July 3 for the purchase of $40,000 bonds, to be used for the construction of water works, sewerage system and electric light plant.

SHREVEPORT.—Mayor Querbes and the Lighting Committee are reported to have decided to recommend that Council enter into a contract with the Shreveport Gas, Electric Light & Power Company for lighting the city for a period of six years.

MAINE.

PITTSFIELD.—Patrons of the electric lighting service of the Sebasticook Power Company were put on the meter system on June 1. The company has notified the consumers that an established rate had been made.

AUBURN.—A contract for lighting the city's streets has been made by the Auburn city government with the Lewiston & Auburn Electric Light Company, the price being $18 a light more than the city is now paying. The company will spend about $5000 installing a new system and will give the city a better lighting service.

BANGOR.—Farson, Leach & Co., of New York, N. Y., are reported to have decided to finance and develop the property of the Bodwell Water Power Company, in Oldtown and Milford. The company will at once construct a concrete dam and an electric power plant to generate about 6,000 horse-power in addition to present development.

MARYLAND.

ELKTON.—B. F. Groff is stated to have purchased the mills and water power at Gilpins Falls, near Bayview, which will be developed for illuminating and manufacturing purposes.

ELLICOTT CITY.—Victor G. Bloede, of Baltimore, treasurer Patapsco Electric & Manufacturing Company, writes that it is proposed to construct a plant on Patapsco River, below Ellicott City, for the purpose of generating electric current for light and power. The approximate capacity of the power plant will be about 900 horse-power.

MASSACHUSETTS.

NANTUCKET.—A charter is reported to have been granted to the Citizens' Gas, Electric & Power Company, of Nantucket.

HAVERHILL.—The Haverhill Electric Company is to rebuild its plant on Water Street at a cost of $25,000.

GLENDALE.—The Monument Mills Company, of Housatonic, is reported to be making plans to develop the water power at Glendale.

SPRINGFIELD.—The Springfield Electric Company, of Springfield, is reported to have secured the contract for electric wiring the new technical high school, for $4700.

NATICK.—The Selectmen have granted the Edison Electric Illuminating Company, of Boston, a franchise for the purpose of running its high-current lines from the Dover line to its local power station.

BROCKTON.—The Gas Commissioners have refused to grant the petition of the Edison Electric Light Company, of Brockton, to issue $175,000 additional capital stock to take up $100,000 bonds and $75,000 notes.

WOBURN.—The Woburn City Council has passed over Mayor Reade's veto an order transferring the franchise of the Woburn Light, Heat & Power Company to the Edison Illuminating Company.

LYNN.—The Gas and Electric Light Commission has authorized the Lynn Gas & Electric Company to issue 2300 shares of new stock, at a value of $200 per share. Part of the proceeds is to be devoted to the payment of indebtedness and the balance to the plant.

BOSTON.—The Gas Commissioners have authorized the United Electric Light Company, of Springfield, to issue 2000 additional shares of capital stock at $260 per share; 820 shares will be used to take up notes and the remainder, 1180 shares, will be applied to additions to plant.

HOLYOKE.—Treasurer R. C. Winchester, of the Holyoke Water Power Company, has received permission from the River and Harbor Commission for the use of a part of the river bed for a site for the new electrical generating power plant. The force of engineers has begun preliminary work on the proposed site.

HOLYOKE.—Plans are reported to have been completed for the new power plant of the Holyoke Water Power Company on the west bank f Connecticut River. The plans call for the construction of a new canal, from which water will be conveyed to a power plant generating 7000 horse-power.

SOUTH FRAMINGHAM.—The Committee on Public Lighting has recommended that all street lights be discontinued July 1. At the annual town meeting $7500 was appropriated for public lighting. The Edison company, however, will not light the town, under the present schedule, short of $9000, nor will a shorter schedule be considered at a reduced price.

QUINCY.—The Massachusetts Electric Light and Gas Commissioners have given a hearing at the Quincy City Council chamber on the petition of Henry L. Kincaide and others of that city, asking for a reduction in the prices charged by the Quincy Electric Light & Power Company for electricity within the limits of that city. Chairman Barker stated the board would take the case under advisement, and in the meantime would compare the prices charged by the Quincy Company with those charged in other cities and towns.

MICHIGAN.

HUDSON.—The Hudson Electric Light Company has been formed with $25,000 capital.

JACKSON.—The directors of the Capital Light & Power Company are reported to have decided to expend about $8000 for new machinery.

REPUBLIC.—The citizens are reported to have voted to issue $20,000 bonds for water works and an electric light plant.

TRENTON.—The village electric light plant and water works are reported to have been destroyed by fire May 28. D. W. Peaume, chief engineer.

MONROE.—The Monroe City Council has apparently become sick of owning a municipal lighting plant. A proposition was made by City Surveyor White to lease the plant for ten years. The plant is for sale.

FORT BRADY.—Contracts have been awarded as follows for lighting Fort Brady: To the General Electric Company, for a supply of transformers, wattmeters and arc lamps, $1211; to W. L. Murdock, of Sault Ste. Marie, for interior and exterior work, $9513, and to the Edison Sault Electric Company, Sault Ste. Marie, for current (interior) at 6.6 cts. per kw.-hour and for exterior lighting $47.50 per arc light per year.

MUSKEGON.—A ten-year contract has been entered into between the Grand Rapids-Muskegon Water Power Electric Company and the directors of the Interurban Railway Company for furnishing power for the propulsion of interurban cars. The Water Power Company proposes to expend $100,000 for machinery for the power station which it proposes to build at the dam now being constructed across the Muskegon River, near Rogers' bridge, about six miles directly south of Grand Rapids.

MINNESOTA.

GIBBON.—This town is reported to be considering the construction of an electric light plant.

SOUTH ST. PAUL.—The City Council has granted A. Baumgarten, John Coats and others a franchise for an electric light plant to cost about $15,000.

MINNEAPOLIS.—Articles of incorporation have been filed with the Secretary of State by the Hughes Electric Company, of Minneapolis; capital stock, $100,000. Incorporators: Alexander H. Hughes, of Minneapolis; E. A. Hughes and W. V. Hughes, of Bismarck, N. D.

MISSISSIPPI.

GREENVILLE.—The Greenville Electric Light & Gas Company was purchased by the Delta Light & Power Company.

STARKVILLE.—Bonds to the amount of $8000 are reported sold, to be used for enlarging the water and light plant.

DURANT.—J. G. Hamilton, mayor, writes that it is proposed to replace the present electric light plant with a larger plant at a cost of $12,000, and bids for construction will be received about July 3.

LAUREL.—The Laurel Improvement Company is reported to have accepted the franchise offered by the city and will begin at once the construction of a light and power plant, at a cost of $25,000.

MISSOURI.

MARSHALL.—The Marshall Light, Heat & Power Company, of New York, has filed articles to show that it has been incorporated under the laws of the State, with a capital stock of $150,000, all of which is to be employed in Missouri. The company's office will be in Marshall.

ST. CHARLES.—The St. Charles Lighting Company was incorporated May 31 with a capital of $100,000. The incorporators are Joseph McCollum, Lloyd Shepard, Charles F. Johnson and Robert H. Lawlor, of East St. Louis, Ill.; Edward Gut, S. O. Fulkerson and C. O. Collier.

MONTANA.

HELENA.—The Missouri River Power Company is reported to have decided to build a second dam across Missouri River, to develop electric power, to cost about $1,000,000.

LIVINGSTON.—President John L. Bright, of the Citizens' Electric Light Company, of this city, has purchased the controlling interest in the Livingston Electric Light Company.

DILLON.—The Dillon Electric Light & Power Company has changed management, the controlling interest of the plant having been sold by Dr. M. A. Miller, of this city, to H. W. Turner, of the Buttle Electric Company.

NEBRASKA.

KEARNEY.—Kuntzen & Isdell, of Kearney, have secured the contract for erecting a power house on the grounds of the State Normal School at Kearney, for $9283.

NEVADA.

RENO.—The Reno Light, Power & Water Company has announced a cut of 75 per cent in its electric lighting rate. This is against the Washoe Power & Development Company, which will turn on current in a few days. The new company is expected to meet the reduction. Recently the Washoe Company offered to furnish current free for the carnival to be given in July, and now the old company comes with an offer to furnish lamps, wires, current and all labor free. Both are wealthy corporations.

NEW HAMPSHIRE.

KEENE.—The contract for lighting the streets has been awarded to the Citizens' Electric Co., of Keene, at $82.50 per year for a 410-watt arc light and $21 per year for 32-c.p. incandescent lights for an all-night, every-night service.

CONCORD.—The Concord Electric Company has closed contracts for the enlargement of its Sewall's Falls plant, and as soon as the work is completed will begin to furnish all the electric power for the operation of the street car lines, an agreement to that effect having been reached with the Boston & Maine Railroad.

LACONIA.—The Committee on Street Lighting of the City Council has taken the preliminary steps for the lighting of The Weirs end of the city by electricity. Already the Laconia Lighting Company, which has a ten-year contract with the city for street lighting, has the work of stringing the wires to the lake well under way. For the first year some twenty-two lamps have been allotted.

NEW JERSEY.

PATERSON.—The Paterson Electric Light, Heat & Power Company has petitioned Council for a franchise for an electric light plant.

CAMDEN.—The Pleasantville Electric Light Company has been incorporated with a capital of $125,000 by Chas. E. Mashold, Augustus H. Riddell and Howard F. Morgan, all of Camden.

CLARKSBORO.—It is proposed to install an electric plant to light the towns of Jefferson, Mount Royde, Clarksboro and Mickleton. A mill at Boody's pond will be converted for the station.

DEAL.—The Elberton Water, Power & Light Company, of Elberton, has secured a franchise to lay mains and conduits for lighting and other purposes in Deal.

JERSEY CITY.—The Sioux City Service Company, of Jersey City, has been incorporated, with a capital of $250,000. The incorporators are Louis B. Dailey, Thomas F. Barrett and B. Stafford Mantz, all of Jersey City.

JERSEY CITY.—The Ajax Light Company, of Jersey City, has been incorporated with a capital stock of $100,000. The incorporators are George M. Wormann, Daniel J. Clark and Harold Morford.

NEWARK.—President Engers, of the Board of Works, has suggested that the city take some steps in the near future to ascertain whether it would be feasible for the municipality to own and operate an electric lighting plant when the contract with the Public Service Corporation expires three years and a half hence.

NEW YORK.

LOCKPORT.—The Niagara, Lockport & Ontario Power Company has purchased a site for the $100,000 transformer station.

POTSDAM.—The Hydraulic & Electrical Power Company has been incorporated with a capital stock of $50,000. The directors are G. W. Sisson, R. L. Sisson and C. H. Sisson, of Potsdam.

TONAWANDA.—The Tonawanda Power Company has secured the contract for lighting the streets and parks with 120 arc lamps for five years at $70 per lamp per year.

NEW YORK.—Plans have been filed for a 4-story and basement brick and stone power-house to be erected at 452 W. 27th Street, by the New York Edison Company, at a cost of $50,000.

OLEAN.—The Natural Gas, Electric Light, Heat & Power Company has been formed; capital, $50,000. Directors: W. R. Page, F. R. Easton and J. L. Page, Olean.

ALDEN.—The Alden Lighting, Heating & Power Company has been incorporated with a capital stock of $200,000. The directors are F. G. Bagley, A. L. Becker, D. E. Klein, Buffalo.

LOCKPORT.—The Lockport Gas & Electric Light Company has filed at Albany a certificate of increase of capital stock from $150,000 to $300,000.

LOCKPORT.—Geo. Schaff, of Buffalo, has secured the contract for constructing a power-house for the Niagara, Lockport & Ontario Power Company, on Niagara River, for about $25,000.

OSWEGO.—The Oswego Light & Power Company has been incorporated with a capital of $100,000. Directors: Henry B. Brewster and Saml. A. Fulford, of Syracuse.

POTSDAM.—Bonds to the amount of $40,000 are about to be sold, the proceeds to be used for the construction of an electric light plant. H. B. Sweet, of Utica, is the engineer.

BUFFALO.—The Niagara Gorge Power Company has been incorporated with a capital of $2,000,000. The directors are J. T. Jones, J. A. Jones, R. E. Powers and H. P. Bissell, of Buffalo.

MINETTO.—The Minetto Light, Heat & Power Company, of Minetto, has been incorporated with a capital stock of $20,000. The directors are C. B. Benson, Minetto; D. B. Page and T. A. Page, Oswego.

OSSINING.—The Hudson Counties Gas & Electric Company, of Ossining, has been incorporated with a capital stock of $100,000. The directors are Moses Ely, A. F. Gotthold and R. R. Logan, New York.

NEW YORK.—The United Public Service Corporation, of New York, has been incorporated with a capital stock of $500,000. The directors are Charles H. Gardner, George W. Peck and A. Edwin Schaffer, New York.

BATAVIA.—The Genesee County Electric Light, Power & Gas Company, of Batavia, has been incorporated with a capital stock of $100,000. The directors are S. B. Storer, Syracuse; R. M. Walker and C. C. Bradley, Batavia.

FISHKILL.—The Southern Dutchess Gas & Electric Company, of Fishkill, has been incorporated with a capital stock of $25,000. The directors are J. T. Smith and E. L. Tompkins, Fishkill Landing, and S. K. Phillips, Mattawan.

PORT JERVIS.—The Orange County Power Company has been incorporated with a capital stock of $50,000. The directors are W. W. Handy, L. L. Marks, New York; Henry Floyd, East Orange, N. J.

TROY.—The Board of Contract and Supply is considering the question of establishing a municipal electric light plant to be used for lighting Monument Square and city buildings in that locality.

NEWARK.—J. L. Rigby, W. L. Mathues and others, all of Philadelphia, Pa., it is stated, have purchased the plant of the New Light, Heat & Power Company. H. M. Whitehead, of Newark, will be manager.

NEW ROCHELLE.—The Northern Westchester Lighting Company has consolidated all the lighting companies in Ossining, Croton, Briarcliff Manor and Pleasantville, and will probably make improvements to the plants purchased.

HOOSICK FALLS.—The Hoosick Falls Illuminating Company has been incorporated to supply gas and electricity, with a capital stock of $150,000. The directors are Roger Lewis, L. C. Tetard, Sherman Cox, R. W. Gifford, of New York, and G. D. Martin, of Greenwich, Conn.

LITTLE FALLS.—The Hudson River Electric Power Company is stated to have applied to City Council, through Attorney Rush F. Lewis, for a franchise to construct a transmission line for the distribution of electricity for lighting, heating and power purposes.

UTICA.—The Central New York Power Company, of Utica, has been incorporated with a capital stock of $1,000,000, to manufacture gas and electricity. The directors are William E. Lewis, Charles B. Watkins, Utica, and Harry S. Patton, Whitesboro.

BUFFALO.—The New York & Lake Erie Power & Transmission Company, of Erie County, has been incorporated with a capital of $100,000 to supply gas and electricity. The directors of the company are J. F. Aldrich, G. A. Ricker, C. F. Powell, Buffalo.

BINGHAMTON.—The Council has awarded to the Binghamton Light, Heat & Power Company the contract for lighting the streets at 23 cts. per night for a term of 3 years for 374 arc lights, and for lighting the city hall and other city property at 6 cts. per kw.-hour.

CASTLETON.—The Castleton Light, Heat & Power Company has been incorporated to operate in Schodack, Castleton, East Greenbush and Rensselaer. The capital stock is $25,000 and the directors are J. D. Smith, T. F. Clifford and F. H. McKnight, Castleton.

DEXTER.—The Dexter Electric Light & Power Company has been incorporated at Albany to furnish light and power in various towns and villages of Jefferson County, capital, $100,000. Directors: Edward Hunter and Catherine J. Hunter, of Dexter; Celestin C. Burns and George H. Burns, of Watertown.

RHINEBECK.—At a recent meeting of the stockholders of the Dutchess Light, Heat & Power Company, of Rhinebeck, the following directors were elected: Frank Herrick, George N. Miller, Thaddeus A. Traver, M. V. B. Schryver, R. Raymond Rikert. Inspectors: Messrs. A. Lee Wager and John Williams.

NORTH CAROLINA.

KINGS MOUNTAIN.—Bids are wanted July 15 for the construction of an electric light plant, to cost about $15,000. J. C. Patrick is city clerk.

MOREHEAD CITY.—Bids will probably be received in July for the construction of water works and an electric light plant.

GRAHAM.—The Graham Water & Electric Light Company has been chartered, with $100,000 capital, by H. L. Millner, of New York, C. P. Hartsell and M. F. Fray, of Washington.

OHIO.

NEWARK.—Electric light bonds to the amount of $15,000 have been sold.

FOREST.—It is proposed to construct an electric light plant here to cost from $5000 to $8000.

FREMONT.—The Fremont Light & Power Company will develop the water power on Sandusky River, near Fremont.

PLYMOUTH.—It was voted to issue $6000 bonds to improve the water works and electric light plant. W. A. Jeffrey is village clerk.

NEWARK.—The Westinghouse Electric & Manufacturing Company has secured the contract for generator, switchboard, arc lamps and regulating

transformer for the municipal electric light plant for about $12,510.

KENTON.—A deal has been closed whereby Richard G. Kerlin and E. M. Kerlin, of this city, come into possession of the local plant of the Kenton Gas & Electric Company, the consideration being $12,000. The Kerlin Brothers will spend about $50,000 in improvements.

NEW STRAITSVILLE.—H. L. Canfield, treasurer Delphos Electric Light & Power Company, Delphos, O., has secured franchises for operating an electric light and power plant at New Straitsville and transmitting current at Shawnee, two miles distant. A complete new installation throughout will be erected and modern equipment installed.

OKLAHOMA TERRITORY.

ANADARKO.—The municipal lighting plant of Anadarko, just completed by the El Reno Light & Power Company, and costing $11,000, was started on the evening of June 4 and the city is now lighted by 28 arc lights. The plant was installed in the water-works power-house.

OREGON.

RICHLAND.—C. F. Hyde and W. H. Strayer, of Baker City, are interested in the construction of an electric plant at Richland.

ASTORIA.—W. W. Whipple has accepted the franchise granted by Council for the purpose of building a telephone, gas and electric light plant in Astoria.

PENNSYLVANIA.

LEWISBURG.—Philadelphia capitalists have purchased the gas works and the electric light plant at Lewisburg.

TAMAQUA.—The Tamaqua Heat, Light & Power Company is reported to have purchased a site for a new plant

READING.—The Reading Illuminating Company petitioned Council for a franchise to erect poles and string wires and furnish light, heat and power.

WILKESBARRE.—The Wilkesbarre Gas & Electric Company contemplates improving its plant, to include changing from direct current to alternating current; adding apparatus of 1350 kilowatts to station capacity; one Curtis turbine, and changing from non-condensing to condensing.

PITTSBURG.—The Johnsonburg Electric Light, Heat & Power Company has applied for a charter. The capital of the company will be $25,000 and the directors for the first year, J. H. Waugh, C. G. Hussey, S. Robinson, A. J. Snodgrass and M. C. Adams all of Pittsburg.

DALLASTOWN.—The York & Windsor Electric Light Company has engaged as manager F. C. Wright, recently superintendent of the Lebanon (Pa.) Edison Company. The Dallastown station has an output of 800 kilowatts and supplies eleven towns in York and Lancaster counties. Eli L. Nissly is president and E. R. Heisey secretary and treasurer.

EASTON.—Under a charter granted to the Consolidated Service Company, of Easton, Pa., a merger of the People's Electric Light & Power Company and the Easton Steam Heating Company has been effected. The charter for the new company, which is capitalized at $200,000, the sum of the capitalization of the two present corporations, was signed by Governor Pennypacker. The officers of the new company in the charter are E. W. Evans, president, and Henry G. Siegfriend, secretary and treasurer.

YORK.—The York Haven Water & Power Company have decided to make an addition to their plant at York Haven. Mr. Henry L. Carter, the president, states that four additional unites will be installed as quickly as possible. This has been made necessary in consequence of the demand for more current. Robert Poole & Co., of Baltimore, are now building the wheels. An addition to the building will be erected to house the units to be installed. The expenditure at this time will be about $100,000. The entire plant will be completed sometime next year, when all of the units intended for installation according to the original plans will be put in. The building will then be extended to the full length of the architect's plans.

RHODE ISLAND.

CUMBERLAND.—The proposition to establish a municipal lighting plant at this place was defeated, by a vote of 153 to 79, by the taxpayers June 14.

CENTRAL FALLS.—The City Council has passed an ordinance appropriating $75,000 for the purchase of a site and the construction of a municipal electric light plant.

SOUTH CAROLINA.

DILLON.—It was voted to accept the franchise recently granted to A. N. Walker and associates for water works and an electric light plant.

CONWAY.—The Conway Light & Power Company has been chartered by the State, with a capital stock of $10,000. D. A. Spivey is president and J. C. Spivey secretary and treasurer.

ROCK HILL.—The Catawba Power Company is making a survey on Wateree, 14 miles below Camden, with a view to constructing a power plant there. Wm. H. Martin, Jr., of Rock Hill, is secretary of the company.

GREENVILLE.—J. F. Grandy & Sons have secured the contract for constructing the dam for the Saluda River Power Company. Orders for machinery and electrical apparatus are reported to have been let.

SOUTH DAKOTA.

YANKTON.—Sandford Donaldson has secured a franchise for an electric light plant.

ARMOUR.—Fred L. Kellogg has secured a franchise for a lighting and heating plant.

MILBANK.—There is an opening here for an electric light system. Mr. H. A. Martens could give further information.

MONTROSE.—Donohue & Williams, of Montrose, write that their electric light plant is about completed, but they desire fixture (electric) catalogues.

TENNESSEE.

WISE.—W. J. Jones is interested in the construction of an electric light plant.

PARSONS.—L. A. Rains and J. W. Fuller are reported interested in the construction of an electric light plant here.

NASHVILLE.—The Southern Electric Company has increased its capital from $20,000 to $40,000 and will enlarge its plant. O. C. Turner is general manager.

LENOIR CITY.—The Lenoir City Light & Power Company, of Loudon County, Tenn., has been chartered; capital stock, $2,500. The incorporators are William Glass, R. M. Galloway and associates.

MURFREESBORO.—The City Gas & Electric Company has contracted with the city for a ten years' service of 75 arc lamps, the franchise being exclusive. Mr. J. H. Nelson is manager of the plant.

CHATTANOOGA.—The Chattanooga & Tennessee River Power Company, of Hamilton County, Tenn., has been chartered, with a $3,000,000 capital stock. The incorporators are Joseph C. Guild and others.

CHATTANOOGA.—The City of Chattanooga has strongly supported, officially, the proposition of C. E. James and J. C. Guild to erect an electric power plant on the Tennessee River at a cost of $300,000. The capital needed is in sight and the company will be chartered in the State of Tennessee.

LAFOLLETTE.—The Lafollette Water, Light & Telephone Company is reported organized, with a capital of $150,000, and will begin construction immediately of water works, an electric light and telephone system. Directors: W. C. Knight, St. Louis, Mo.; F. A. Joss, Indianapolis, Ind., and T. C. Whalen, Indianapolis, Ind.

TEXAS.

DENTON.—The city is reported to have purchased the plant of the Denton Water, Light & Power Co. and will take possession on July 1.

DALLAS.—The citizens have voted to issue bonds to the amount of $100,000 for an electric light plant.

HOUSTON.—The electric light plant at Houston Heights will be renovated and put in operation by O. M. Carter. A quantity of new machinery will be added to the equipment.

DEL RIO.—The Del Rio Electric Light & Ice Company has been incorporated with a capital of $20,000. The incorporators are J. D. Darden, of Jericho; John M. Gray, of Del Rio, and Maynard Gunsel, of Albuquerque, New Mexico.

UTAH.

LOGAN.—The city will install a second unit at the municipal lighting plant. Work is to be completed by September 1.

GARDEN CITY.—The Council is considering issuing bonds for the construction of an electric light plant.

PARK CITY.—The Summit Electric Company has been formed with a capital of $100,000 by Henry Shields, Willard F. Snyder and others, of Salt Lake City, to distribute electric light and power in Park City.

VERMONT.

JOHNSON.—Johnson has voted to secure the Ithiel Falls, and to equip them so as to provide electric power. The estimated expense is $12,000.

STAMFORD.—The Stamford Heat & Power Company has organized with the following directors: John Tudor and Charles D. Houghton, of Stamford; C. H. Cutting, H. T. Cady, E. A. Richardson, J. D. Hunter and F. S. Richardson, of North Adams, Mass. The officers are J. D. Hunter, president; H. T. Cady, vice-president; C. D. Houghton, clerk; F. S. Richardson, treasurer.

VIRGINIA.

FREDERICKSBURG.—The city has voted not to sell the municipal electric light plant and franchise. The proposition was defeated by a majority of 314.

PETERSBURG.—The town of Petersburg is considering the question of municipal ownership of lighting facilities. J. M. Quick is chairman of the light committee.

STAUNTON.—The Blue Ridge Light & Power Company has been incorporated at Staunton by John M. Spotts, president and treasurer; C. P. Bowman, secretary and vice-president. The capital stock is $50,000, and the concern has the right to operate a railroad with any kind of power desired.

RICHMOND.—A move is on foot for the city to operate and maintain an electric light plant. The Virginia Passenger & Power Company now furnishes the light for the city, and this is one of the big assets of the company. The attorneys for the road, it is stated, are not fighting the new municipal light scheme further than to undertake to demonstrate to the Council that it is not to the city's interest at this time to go into such a project.

WASHINGTON.

SUMAS.—H. W. Vanderhoof has asked the City Council for an electric lighting plant franchise.

CHEHALIS.—Harry West, present owner of the electric light plant, will construct a 400-h.p. plant on Coal Creek, north of town.

WISCONSIN.

GREEN BAY.—The Green Bay Gas & Electric Company has decided to expend about $200,000 in improvements.

JANESVILLE.—The contract for lighting the city has been awarded to the Janesville Electric Company, of Janesville, at $62 per light per year for 200 or more arc lights.

WAUWATOSA.—J. M. Harrison, of Milwaukee, has been selected by the County Board and Committee on Public Buildings to prepare plans and estimates for a central heat, light and pumping station for Wauwatosa.

MILWAUKEE.—The electric lighting company of Rio, Wis., is having plans and specifications prepared for one 60-inch turbine wheel, one 75-kw. A. C. generator with step-up and step-down transformers, with 4 miles of lines. Milwaukee Engineering Company, consulting engineers.

American Electrician.

Vol. XVII. New York, August, 1905. No. 8.

HYDRO-ELECTRIC DEVELOPMENT IN NORWAY.

ELECTRIC GENERATING STATION AT GLOMMEN NEAR, KYKKELSRUD.

BY L. RAMAKERS.

Of all countries in Europe abounding in water power, Norway excells. Furrowed with multi-branched water courses which plunge from the slopes of the mountains and rush along narrow beds until absorbed by one of the many fjords whose polyp-like arms project far inland, the "Land of the Midnight Sun" possesses natural powers which are both useful and ornamental.

The progress made in the field of electric transmission of power, the multifarious utility of electric energy for industrial purposes, and finally the advantage which hydraulic power possesses in comparison with the mechanical force obtained from coal, liquid fuel, etc., viz.: that the working costs are not influenced by any market fluctuations—all point to the great utility of existing water courses. It was this which led the Aktieselskabet Glommens Traesliberei of Christiania in 1899, in conjunction with the Elektrisitæts-Aktiengesellschaft vorm Schuckert & Co., to use the water of the Glommen for industrial purposes.

The Glommen is the largest river in Norway. The area it covers extends from north to south almost from Tronthjem to Frederiksstad, at which latter place it flows into the Christiania Fjord. Like most Norwegian rivers, the river area of the Glommen also comprises several inland lakes; the largest of these, the Mjoesen, has a superficial area of 559 sq. km. and is situated 123 m. (403 ft.) above the level of the sea.

To the south of Lake Mjoesen, and at a distance of about 60 km. (37 miles) is Lake Oejeren, which lies about 153 m. (502 ft.) above the level of the sea, and communicates with Lake Mjoesen through the Glommen. Some distance below the Oejeren there are several falls of different heights, the aggregate height of fall being 260 feet. The Kykkelsrud, which is about the middle of this series of falls, comprises three falls—the Dalsfos, the Kykkelsrudfos and the Vervenfos, the aggregate height of the fall of which is 64 feet.

FIG. 1.—HYDRO-ELECTRIC STATION AT GLOMMEN, NORWAY.

The water of the fall is collected by a dam at the Kykkelsrudfos, a canal more than half a mile long, leading past the Vervenfos, where the power house is situated. The natural conditions of the spot chosen are

favorable, inasmuch as the river at this place has two arms, one at each side of Haltorp Island, and there is rock all the way across. The dam over the left stream is now completed and is a structure of no small importance. No special difficulties, however, were encountered in its construction. The dam over the right stream will not be built until the consumption of power is increased about 12,000 horse-power, the present installation yielding sufficient water and fall for that capacity. The natural conditions for damming the right stream are essity the canal may be emptied through a bottom outlet above the reservoir, 90 square feet in area; and in order to protect the turbines against stone and gravel the distribution reservoir is placed on a higher level than that of the canal. The pipes leading from the reservoir to the turbines are of concrete or iron and channels are also blasted in the rock. The provisional power house, shown by Fig. 1, has a capacity of four turbines of 3000 horse-power each and three smaller ones, two of 300 horse-power and one of 500 horse-power. are driven by electric motors and work with a pressure of about 30 atmospheres. The turbines were supplied by Escher, Wyss & Co., of Zurich, and by the firm of J. M. Voith, of Heidelheim. The generators were supplied by Schuckert & Co. These are of the horizontal rotating field type running at 150 r.p.m., and generating 2500 kilovolt-amperes, at a tensoin of 5000 volts. The current is three-phase, 50 cycles. The exciters are designed for a pressure of 115 volts and deliver 1580 amperes. The equipment besides these includes six 950-kw.

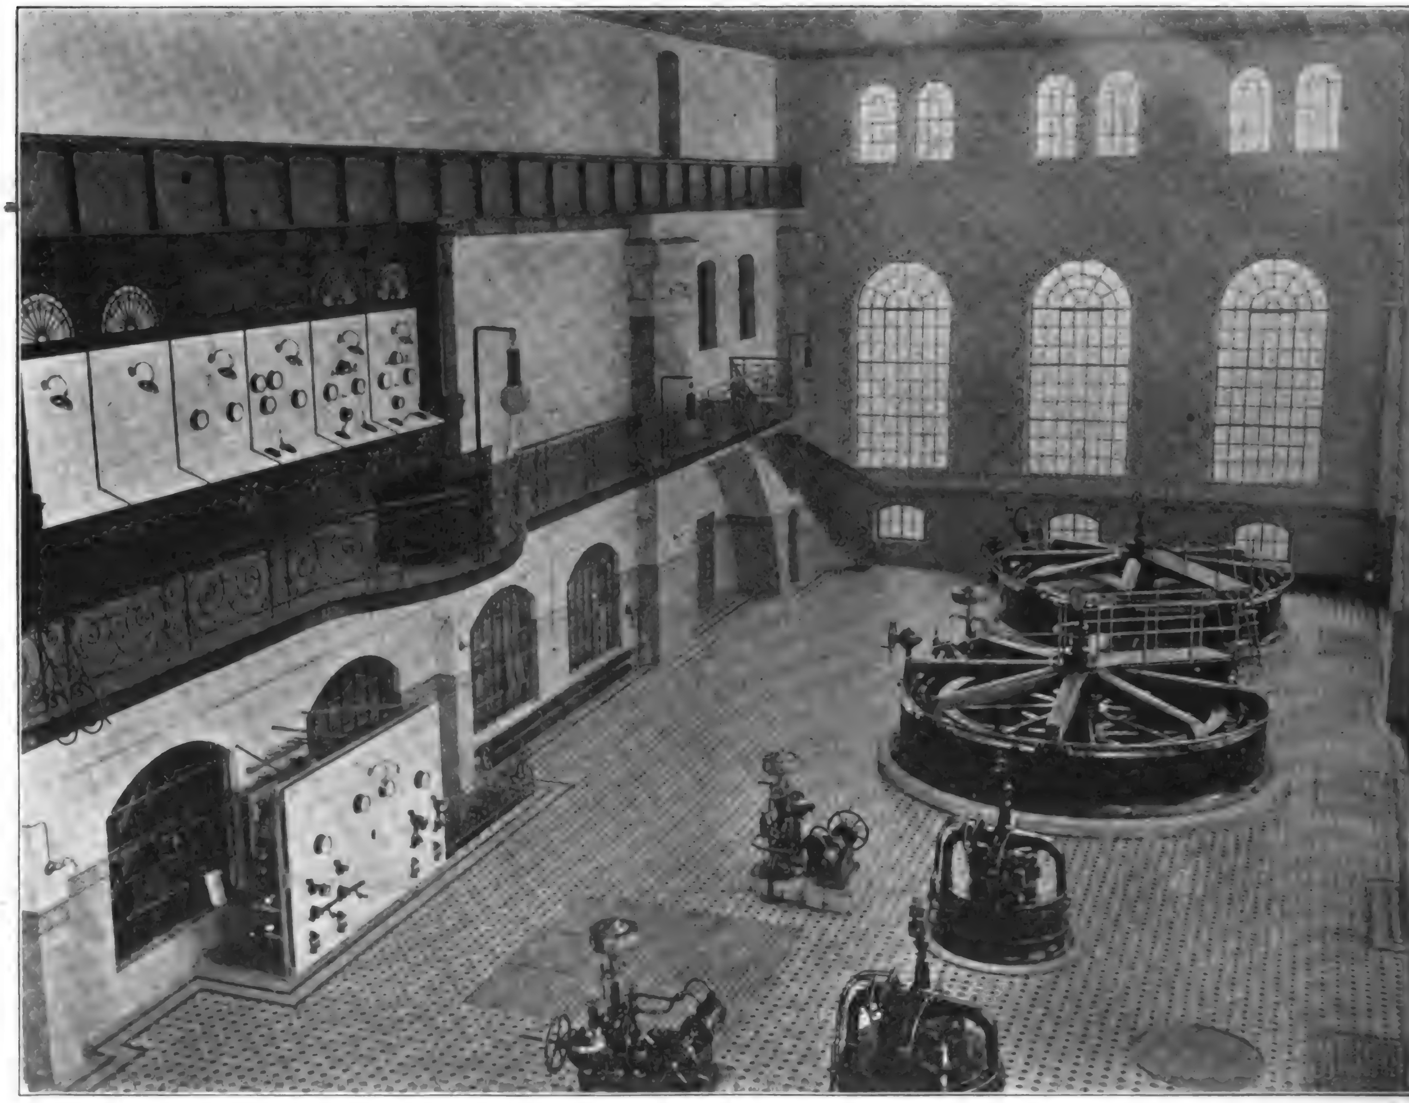

FIG. 2.—INTERIOR OF THE POWER HOUSE AT GLOMMEN.

favorable, there being rock and shallow water right across. Above the dam there will be a reservoir with almost still water.

The inlet canal on the left side of the river is comparatively broad at the upper end, being about 80 feet, and the fall of the bottom of the canal is greater here than in its other parts, being almost 4 per cent on the first 330 feet and on the remaining 3000 feet being 1 to 660, with a breadth at the bottom of 27 feet. The slope at the side of the canal is 1 to 10. The canal is partly blasted in rock, partly dug in earth and in various places concrete walls have been built. A distributing reservoir is situated at the end of the inlet canal, whence the water is conveyed to the vertical turbines in the power house. In case of nec-

When eventually completed the plant will comprise eight turbines of 5,000 horse-power in addition to the four turbines already installed, representing an aggregate of 52,000 horse-power, which is increased to 53,060 horse-power by the small turbines used for driving the exciters. Of this only 43,060 horse-power can be used simultaneously, 10,000 horse-power being held as reserve.

The power station is located at the bottom of the Vervenfos close to the distribution reservoir. It has a length of 155 feet and a breadth of 88 feet. The turbines are placed in the basement and from them vertical shafts 28 feet long go to the generators in the room, directly over the turbines. In the basement are also found the oil pumps required for regulating the turbines. These

transformers having a primary e.m.f. of 5000 volts and delivering a secondary e.m.f. of 20,000 volts.

The main generators are all connected to a common set of bus-bars and from these the circuits lead to the transformer room, where the pressure is stepped up to 20,000 volts; the lines then go back to a high-tension rack above the transformer room. The switchboard for the exciters is situated on the main floor with the generators, as shown in Fig. 2. Fig. 3 is a view of the rear of the main switchboard and Fig. 4 is a view of the transformer room. Special care has been taken to arrange the wires and apparatus in such a way as to be safe in working and within easy control. All the switches, fuses, meters and current trans-

formers and likewise all leads conveying high-tension current are placed in special iron frames and kept separate from the switchboard. This latter has no parts that convey high tension either from the front or from the rear, the rear containing the exciter leads and the wires conveying current to the measuring apparatus. It is also provided with the necessary devices for manipulating the regulating resistance shown above the switchboard in Fig. 3, and in addition with the mechanism for operating the distant high-tension switches. The iron framework shown to the rear of the switchboard in Fig. 3 contains the bus-bars and apparatus carrying 5000 volts. The oil switches for the generators are mounted on top, then follow the corresponding change-over switches and below these the bus-bars with their distance or separating pieces. The measuring instruments and current transformers are inserted in suitable positions and the corresponding fuses are mounted in marble compartments. To the rear of this framework is another somewhat similar, which has mounted on it all of the apparatus and bus-bars carrying 20,000 volts, including the distant lead fuses.

Directly beneath this room and in the rear of the small switchboard shown in Fig. 2 is the transformer room which extends the length of the building. The transformers are situated in the center of the room and on either side of them are tracks, so that each transformer can be erected or removed in the shortest possible time by means of a suitable car. These transformers are of the oil-cooled type.

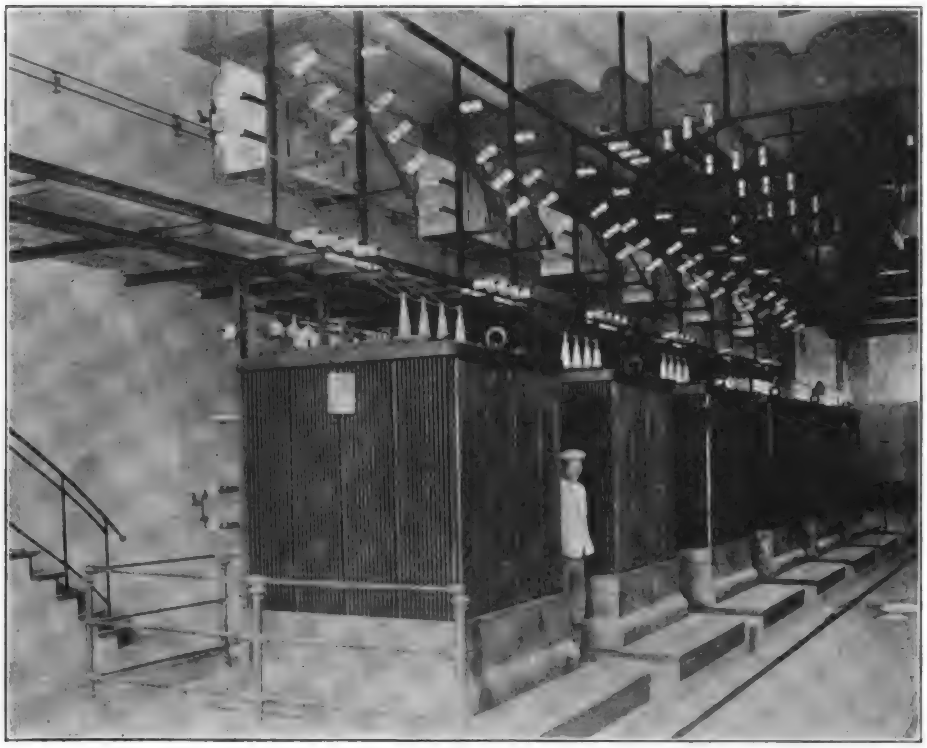

FIG. 4.—TRANSFORMER ROOM IN THE GLOMMEN CENTRAL STATION.

FIG. 3.—REAR OF THE MAIN SWITCHBOARD, SHOWING HIGH-TENSION SWITCH GEAR.

The transmission line is intended to comprise five distinct lines, four running north and one south. The pole lines have already been erected to the north for a distance of 63 km. (39 miles). Each of them is intended for two three-phase transmission circuits, but at present only one three-phase circuit is carried on each pole line. Seven sub-stations are situated along the route of the transmission line. These are provided with oil-cooled transformers for reducing the 20,000-volt current to 5000 volts. Current at this potential is conveyed to various points of consumption, where it is further reduced to 220 volts. Three and a half years were expended in constructing this system, which was placed in operation in September, 1903.

Steel Cables.—In power transmission work spans have occasionally to be dealt with which cannot be carried out with copper conductors, and resort has then to be had to steel cables. The use of such cables would appear to involve an excessive drop. In order to investigate the matter the Allgemeine Elektricitäts Gesellschaft has recently carried out some experiments, the results of which show that the drop with alternating currents is not so much in excess of that obtained with direct currents as might have been expected. The difference increased with the cross-section of the conductor and the current, and decreases, for a given total cross-section, as the strands are made smaller and more numerous.

APPLICATION OF ELECTRIC POWER TO AUXILIARY MACHINERY IN THE NAVY.

BY L. C. BROOKS.

During the last few years considerable progress has been made by the United States Navy in equipping auxiliary machinery such as boat cranes, deck winches, turret gear, ammunition hoists, ventilating fans and small pumps with electric power. The *Kearsarge* and *Kentucky*, which were put in commission in 1900, were far ahead of their day in the application of electric drive, and no particular advancement from these ships was made until the six armored cruisers, *Pennsylvania, West Virginia, California, Colorado, Maryland* and *South Dakota*, known as the *Pennsylvania* class, were developed. These ships, the fastest in the Navy, being of 22 knots speed, will all be in commission by the end of the present year, and are the first of the first-class ships to be fitted with a 125-volt generating plant. The armored cruisers *Tennessee* and class, and the battleships *Connecticut* and class, which are at present building under contract, have an electric equipment quite similar to the *Pennsylvania* class. A comparison of the equipment for these ships will be found in the accompanying table.

TABLE I.—COMPARATIVE DATA.

	Battleships Kearsarge and Kentucky.	Armored cruisers Pennsylvania and Class.	Armored cruisers Tennessee and class.
Date put in commission	1900	1905	1906
Length on load water line, ft.	368	502	502
Displacement, tons	11,600	13,785	14,500
Contract speed, knots	16	22	22
Generator capacity, kw.	350	500	600
Voltage	80	125	125
Turret Turning.			
Guns in each turret	2 8-in. 2 12-in.	2 8-in.	2 10-in.
Est. rotating weight, tons	710	125	235
No. of motors to turn each turret	2	2	2
System of motor control	Ward Leonard	Ward Leonard	Ward Leonard
Motors, how connected	Parallel	Series	Series.
Coefficient of rolling friction	.045	—	—
Ventilation.			
No. of electric fans installed	13	27	27
Nat. air delivered, cu. ft. per minute, restricted delivery		118,800	111,200
Est. current required for above, amperes	1080	800	725
Boat Cranes.			
No. installed on ship	4	4	4
No. motors installed per crane	1	2	2
Capacity of large cranes, lbs.	16,000	33,000	33,000
Capacity of small cranes, lbs.	3,000	5,600	10,000
Electric deck winches installed, number	4	7	6
Electric chain ammunition hoists, number	10	34	30
Electric whip ammunition hoists, number	2	4	3
Electric ammunition conveyors, number	0	0	6
Electric power doors and hatches, number	0	35	41
Work shop, how operated	Steam	Electric	Electric
Fresh water pumps, how operated	Hand	"	"
Drain pumps, how operated	—	"	"
Torpedo air compressor, how operated	Steam	"	"
Laundry machinery, how operated	—	"	"
Turret ammunition hoists, how operated	Electric	"	"
Turret elevating gear, how operated	"	"	"
Turret rammers, how operated	"	"	"

The latest practice for dynamo room arrangement is to have two separate dynamo rooms, complete with generators, pumps, condensers, etc., which are interconnected through switches on the switchboard, so that in case of accident if all of the machines in one room are disabled, the feeders from that room may be supplied with power from the machines in the other room. The distribution switchboards, at which terminate the feeders supplying power to the various auxiliaries and lighting circuits, are located in separate, water-tight compartments. The feeders are run in enameled iron conduit except in very unexposed places, where porcelain hangers are used.

The electric appliances for the auxiliaries are each manufactured under special requirements for each case, which are, in general, as follows:

Motors:—Motors to be wound for 125 volts, direct current.

Motors above 4 horse-power to be multipolar.

The variation of speed between no load and full load of constant-speed motors not to be more than 9 per cent for motors below 5 horse-power and 6 per cent for motors of 5 horse-power and above.

Inclosed motors to be provided with water-tight hand holes of sufficient size for access to the commutator, brushes, field coils, etc., and the leads running through the frame to have stuffing tubes.

The series and shunt field coils of compound motors to be separate. The windings of all field coils to be protected from mechanical injury and no insulating substance used that can be injured by a temperature of 100° C. The armature to be of the iron-clad type, built up of thin laminated discs of soft iron or steel with punched slots and coils easily removable.

The commutator segments to be of hard-drawn or tempered copper, insulated from each other and from the shell by pure mica.

The brushes to be of carbon, to carry not more than 30 amperes per square inch at full load of the motor, and to give perfect commutation without injury to the commutator.

The brush holders to be readily accessible, of the sliding, shunt socket type and made entirely of non-corrosive metal, the springs to be of phosphor-bronze.

All small parts, except permanent fittings, to be of non-corrosive material. All connections liable to become loose to be provided with locking devices.

Controllers:—When located in exposed locations to be absolutely water-tight.

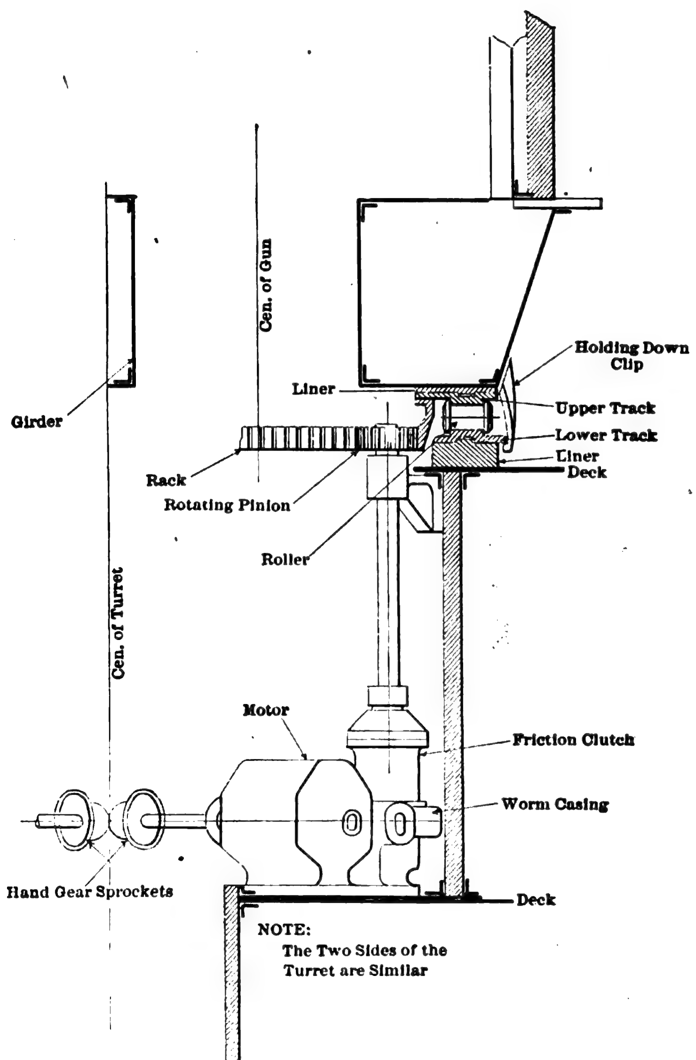

FIG. 1.—ARRANGEMENT OF TURRET-TURNING GEAR.

Fingers and contacts to be of ample size and strength, the fingers to have spring tension.

All flat springs to be of phosphor-bronze and helical springs to be of phosphor-bronze or copper-plated steel.

All insulation to be moisture-proof and fire-proof where exposed to the arcing at contacts.

Operating levers to be easily moved by one hand. The graduations on top of the controller to coincide with the contact points. A notched disc on the controller spindle, held by a spring-operated pawl, to

retain the lever accurately at the various graduations.

All small fittings to be made of non-corrosive material.

Controlling Panels:—Controlling panels to consist of an insulating base with a black polish finish, on the front of which are mounted a main-line switch with enclosed fuses, a starting arm with automatic, no-voltage release and an overload circuit-breaker, the necessary resistances being mounted on the back.

Panels for operating motors of less than 3 horse-power may have a double-pole circuit-breaker operated independently in each lead in place of the switch, fuses and circuit-breaker mentioned above.

Panels arranged for speed control by field resistance to be so constructed that the motor cannot be started on weak field.

Panels arranged for speed control by armature resistance to be so constructed that the starting arm will stay only on contacts designed for continuous running.

The no-voltage release to be responsive only to the line voltage and either bring the starting arm to the off position or open the circuit-breaker.

The circuit-breaker to have independent contacts, must open the armature circuit under any conditions of overload and so interconnected with the starting arm that the circuit-breaker cannot be closed except with the starting arm in the off position.

All insulating materials to be non-combustible, non-absorbent, and not damageable by moisture or heating to a temperature of 150° C.

The frame of the panel to be insulated from the hull of the ship.

The construction of springs, contacts and small fittings to be the same as for controllers.

All resistances to be mounted and insulated such that the result of a burn-out would be practically the same as would occur with an entirely enclosed resistance. All starting resistances to be capable of carrying 50 per cent overload for one minute and 100 per cent overload for 20 seconds.

Rheostats:—The rheostats for each auxiliary to be capable of dissipating heat at such a rate that the temperature in any part shall not rise more than 100° C. above the surrounding air when full-load current is being carried.

The insulating material to be subject to the same requirements as for controlling panels, also firmly secured in and insulated from the supporting frame which is to be insulated from the ship.

The resistance material to be non-corrosive and not damageable by salt water or a temperature of 150° C.

Circuit-Breakers:—The circuit-breakers to be adjustable and able to carry the full rated current of the machine they protect without heating any of the parts and to open the circuit without holding the arc or burning the contacts, which are to be of a simple construction and easily renewable.

Magnetic windings to be thoroughly insulated.

Flat springs to be of phosphor-bronze and helical springs to be of copper-plated steel.

Oxidizable metals, if used, to be thoroughly protected by copper plating.

Tests:—When installing machinery of any character the point that should receive the most attention is the one of preliminary tests.

A small outlay spent in making tests at the time the apparatus is installed, to determine if it will satisfactorily perform the service required, will prove a great saving in the end by decreasing the amount of repairs and loss of time for the apparatus in use.

In the navy work the electrical appliances are tested at the works of the manufacturers by running the motors for a specified time at full load, at the end of which the temperature rises above the surrounding air for the various parts must not exceed the following:

Part.	Open-type motors.	Inclosed motors.
Commutator	40°C	50°C
Field windings	40°C	50°C
All other parts	35°C	45°C
Bearings	30°C	30°C

Tests are also made to determine the fit of parts, balance of the armature, noise, commutation, dielectric strength, insulation resistance, efficiency and speed variation.

After installation on ship the completed apparatus is given a heat run for a specified time under the maximum working conditions to determine if the machinery is strong enough to perform the work intended and the heating of the motors not be above the limits allowed on the shop tests.

Turret Turning Gear:—Each turret is

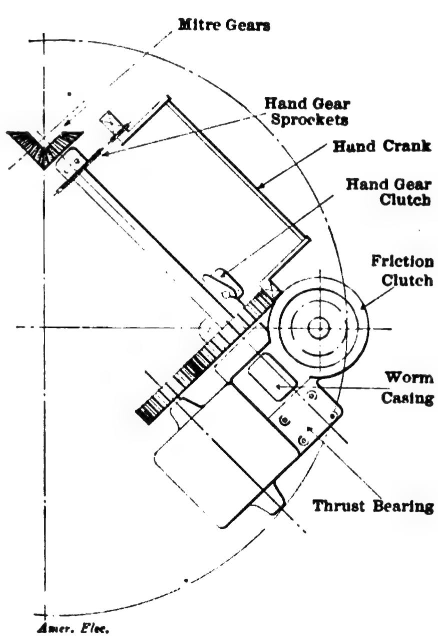

FIG. 2.—PLAN OF TURRET-TURNING GEAR.

turned by two enclosed, shunt-wound motors operating through a system of gearing, a typical arrangement being shown in Figs. 1 and 2. A pinion on the end of the motor shaft engages a gear on the worm shaft, the two motors being connected together by means of a pair of mitres on the extended end of this shaft. The worm drives a horizontal worm wheel which is connected to the vertical shaft through a friction clutch. The rotating pinion, which is secured to the upper end of the vertical shaft, engages the rack which is secured to the upper track, thereby driving the turret. The friction clutch mentioned above is of either the cone or disc type and is designed to protect the gearing from injury due to sudden stopping of the turret, impact of firing the guns or being struck by a shot. During ordinary running conditions it is set down sufficiently to drive the turret without slipping.

Automatic stops are fitted which will turn the controller to the "off" position when the turret reaches the limits of train in either direction. Positive mechanical stops are also fitted as a further safeguard. A dial indicator is fitted in the sighting hood so that the operator may note the position of the turret at any instant. When not being used the turret is held in mid position by blocking wedges.

Great care is exercised to get an accurate fit between the tracks and rollers. The tracks are turned to a true surface and exact size after being secured in place. The rollers are of forged nickel steel and turned to fit the tracks with a clearance of 1/16 in. Holding-down clips secured to the pan of the turret prevent the rollers from leaving the tracks, due to the impact when firing the guns. A hand gear is provided for use when the motors become inoperative from any cause.

Present practice requires the turret to turn at a minimum rate of one rotation per hour and a maximum rate of one rotation per minute. To accomplish this variation of speed with smooth starting and stopping, the motors are operated on the Ward Leonard system of speed control, the motors being connected in series.

This method of speed control depends upon the principle that the speed of the motor armature running in a constant magnetic field is proportional to the volts impressed upon the brushes. This requires a generator for each turret. In some instances one of the regular generators is used, while in others a special motor generator set is installed near the turret.

A diagram of the connections required when one of the regular generators is used is shown in Fig. 3. The field rheostat of the generator is cut out and in its place a special rheostat in the turret is used, which is operated by the controller. The series coil of the generator is shunted by a resistance, so that the series coil may have a slight effect in building up the voltage of the generator and give the turret a prompt start. The brushes of the motor and generator are connected together through the switches, etc., and the fields of each are separately excited from the ship's power.

As the generator is driven at a constant speed, the volts delivered to the motor armature are approximately proportional to the shunt field excitation, which is controlled by the operator in the turret.

When the turret controller is in the "off" position, the motor brushes are connected through a low resistance, so that if the armatures revolve they generate a large current

which produces a powerful braking effect and stops the turret.

By the motors being connected in series, one-half of the working voltage and the total current is available for each motor, thus giving a powerful starting torque and very fine increments of speed.

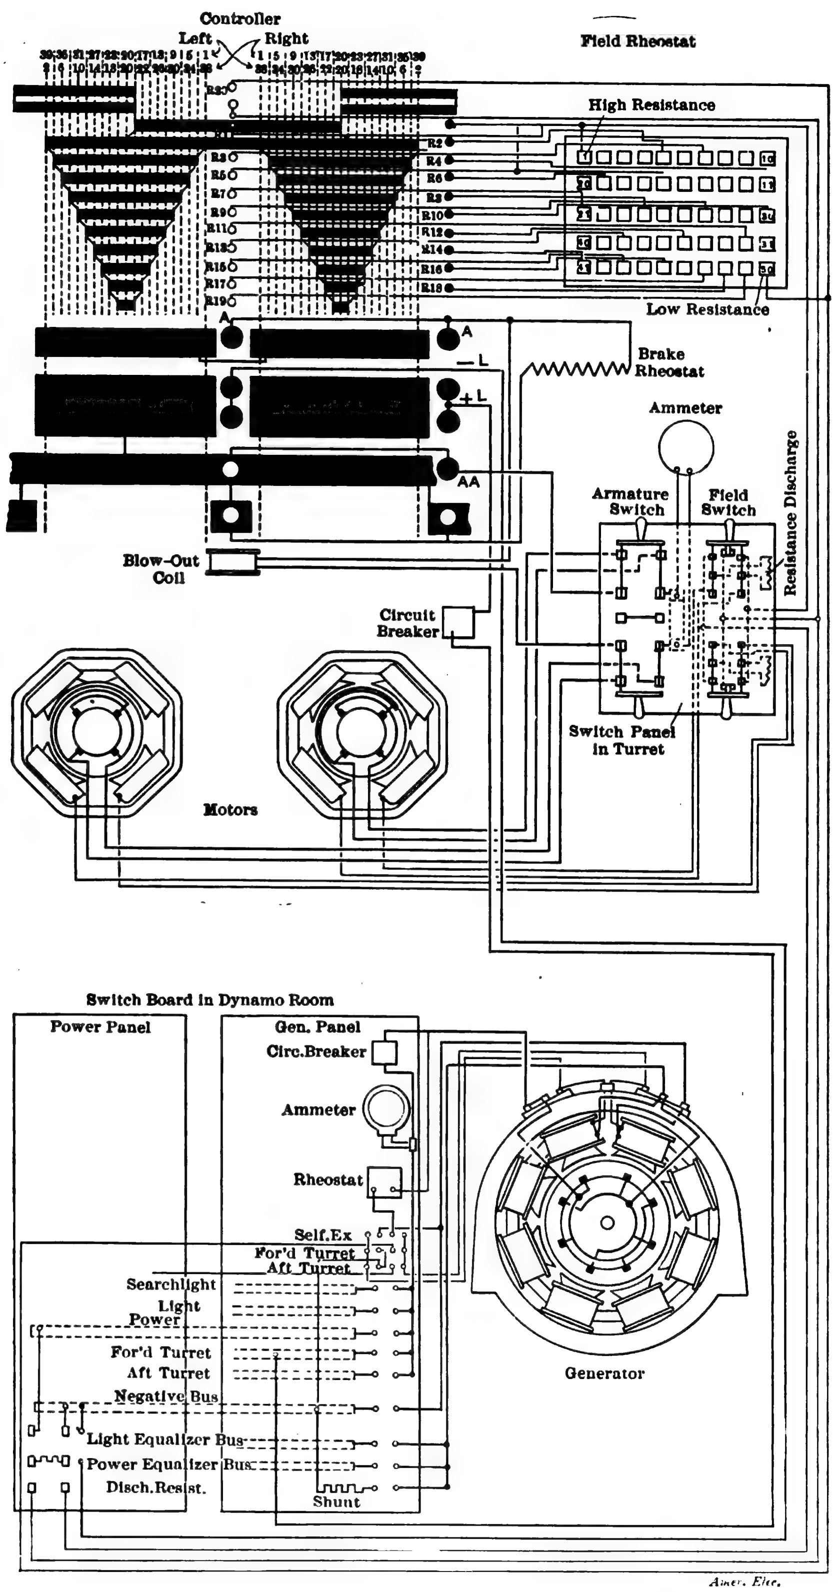

FIG. 3.—DIAGRAM OF CONNECTIONS FOR TURRET-TURNING SYSTEM.

There are usually 25 speed positions on the controller, the first 20 being with the motors at full field at a maximum of about half speed. During the last five positions the motor fields are weakened, the generator rheostat being used and the motors will run at full speed on the last position of the controller.

The motors are of sufficient size, so that should one become disabled it may be cut out by means of switches, and the turret operated by one motor at full field.

Gun Elevating and Loading Gear.—The guns in the turrets are elevated by power and the shells are rammed in the gun by power, hand operation being employed on the smaller guns, 7-in. and less.

For elevating a 12-in. gun, an enclosed, shunt-wound motor is geared to a revolving screw, which raises or lowers a nut cross-head, which operates the gun through connecting rods. In the case of the 8-in. gun, the motor, through a pair of spur gears, a pair of mitres and a worm and worm wheel drives a pinion which engages a segment of a rack secured to the gun carriage.

The elevating motor is operated on the Ward Leonard system of speed control through a reversing rheostat. A small motor-generator set located conveniently near the gun and driven by power from the ship's circuit furnishes the current for the elevating motor.

The rammer consists of a telescopic tube operated through spur and chain gearing by an enclosed, series-wound motor. A friction slip clutch is fitted in the main gear to prevent damage when the shell is seated in the gun.

The motor is operated on ordinary rheo-

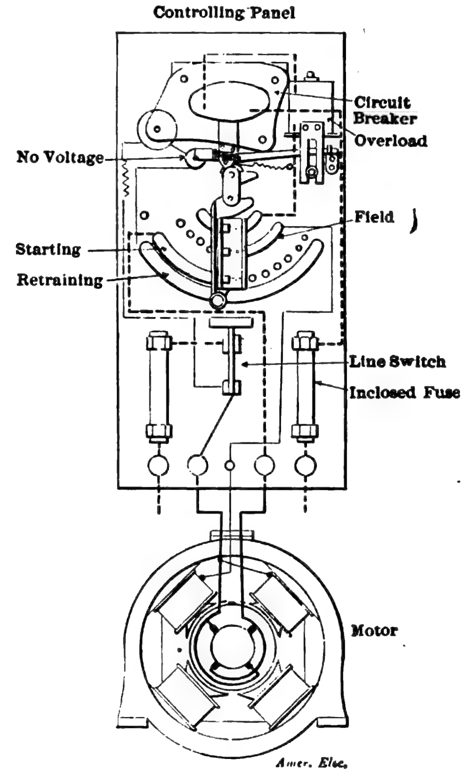

FIG. 4.—DIAGRAM OF CONNECTIONS FOR VENTILATION MOTOR.

static control and protected by fuses as at the instant the shell is seated in the gun a current greatly in excess of the power of the motor is required, while a small amount of current is required when the shell is sliding along the breach.

Ventilation:—The ventilation of a modern ship is very important and a great deal of care is exercised in locating the fans and laying out the piping.

A large number of small size fans are used, thereby reducing to a minimum the piercing of water-tight bulkheads, the number of automatic valves and the amount of water-tight piping. When it is necessary to pierce a water-tight bulkhead, a butterfly valve operated from a convenient point is used, and the ends of ducts leading to magazines and other important compartments are fitted with automatic valves. Adjustable elbows are used for outlets in all

quarters and living spaces and stationary bellmouths are used in other places. Brass piping is used in the magazines, galvanized wrought-steel tubing is used in the coal bunkers and galvanized sheet-steel is used in other places.

It has been found by experiment that the friction of a 20-ft. length of pipe or a 90° bend will reduce the velocity of the air 10 per cent, and allowance must be made for this in designing the size of piping and outlets. Natural exhausts of twice the area of the supply are fitted in all magazines.

All spaces are ventilated on the supply system, except washrooms and water-closets, which are ventilated by exhaust.

The fans are required to be of a sufficient size to give the following changes of air, when running at one ounce pressure: Quarters inside of armor, once in 4 minutes; quarters outside of armor, once in 12 minutes; store-rooms, once in 8 minutes; wash-rooms and water-closets, once in 6 minutes; evaporator rooms, once in 2½ minutes; engine and steering gear rooms, once in 2 minutes; air spaces over boilers and around magazines, once in 2 minutes; dynamo rooms, once in ¾ minute.

The motors are shunt wound, of the open or enclosed type, as the location requires, and operated through controlling panels. They are required to drive the fans at a speed sufficient to deliver the specified amount of air at one ounce pressure and capable of an increase in speed and power sufficient to deliver a specified amount of air at one and one-half ounces pressure, restricted delivery.

The shop tests consist of an eight-hour run at both slow and full speed, the motors driving the fans at open outlet. After the fans and piping are installed on the ship a service test of four days' continuous running at full speed is required to insure satisfactory operation of the motors and proper deliveries of air.

A typical diagram of connections of a motor and a type of controlling panel that has proved very satisfactory in service is shown in Fig. 4.

Boat Cranes: For handling the steam cutters and other small boats, boat cranes are provided to be power-operated from the weather deck. An arrangement that has given very satisfactory results is shown in Figs. 5 and 6. The crane is of the form of a davit, built of structural steel, with a steady bearing at the weather deck and the second deck beneath. At the first deck beneath the weather deck is fitted a roller bearing of sufficient size to support the complete crane with the load. All parts of the crane requiring strength are of steel and designed for a maximum fibre strain of 7,500 pounds per sq. in.

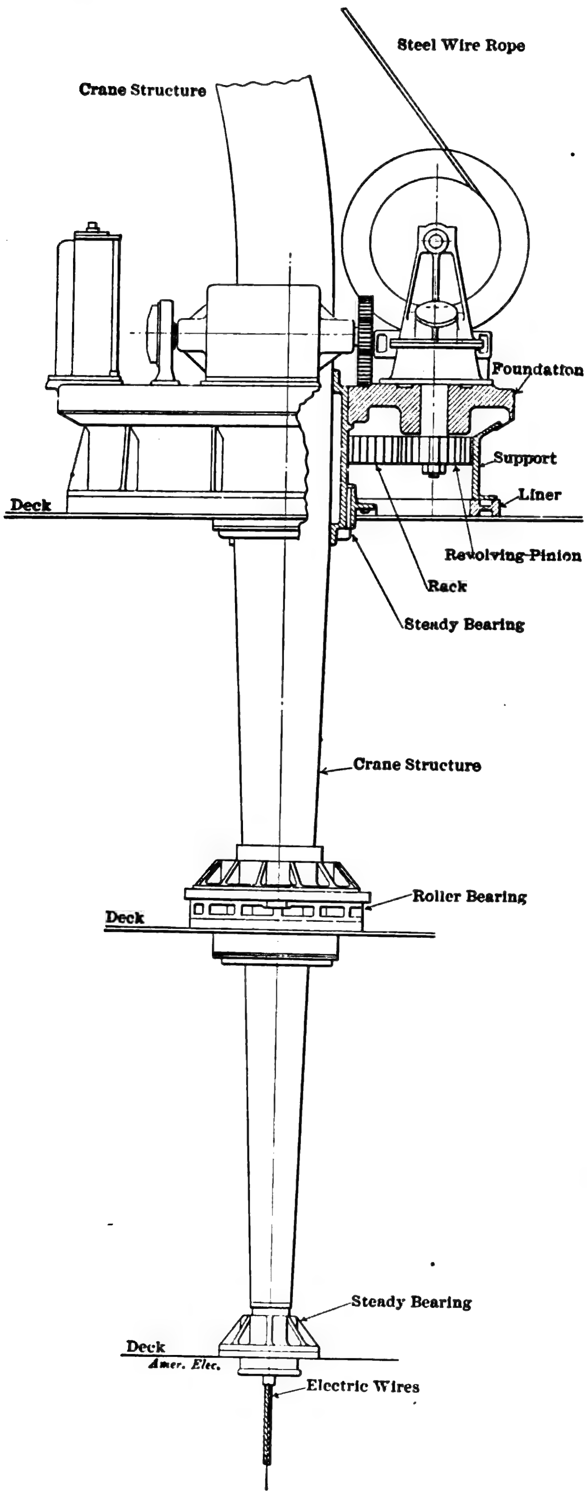

FIG. 5.—ARRANGEMENT OF BOAT CRANE.

The power for operating the cranes is furnished by two inclosed, series-wound motors, one for hoisting the load and one for rotating the crane. The hoisting motor operates through a pair of spur gears, a worm and vertical worm-wheel which is secured to the drum. The hoisting rope leads off the drum over a guide and sheaves in the boom-head to the bottom block and is arranged for two-part or four-part hoisting, according to the size of the load for which the crane is designed. The rotating motor operates through a pair of spur gears, a worm and horizontal worm-wheel and a pinion and rack. The worm-wheel and rotating pinion are secured to the same vertical shaft, and the rack is a part of the support which is secured to the deck, the outboard section being portable. The foundation platform on which the machine is mounted is firmly secured to the crane structure.

The commutator ends of the motor shafts are fitted with magnetic brakes of the disc type which are of sufficient power to hold the full load of the crane.

The controller is of the two-cylinder type, one cylinder for each motor, with the circuit breakers mounted between the cylinders. The rheostats are secured to the under side of the foundation, a manhole in the support providing access for inspection. The feeder wires pass through the lower bearing up inside of the crane.

The most important part of a boat crane equipment is the automatic mechanical brake which is fitted on the worm shaft of the hoisting gear. This brake must be so constructed as to absorb no power when hoisting the load, and control the load when lowering so that the rope speed will not exceed twice the hoisting speed. On account of the great distance through which the load is moved, this brake must be designed with ample allowance for dissipating the heat generated in lowering. Very satisfactory results have been obtained in service with brakes of the Weston type, disc type and cone type.

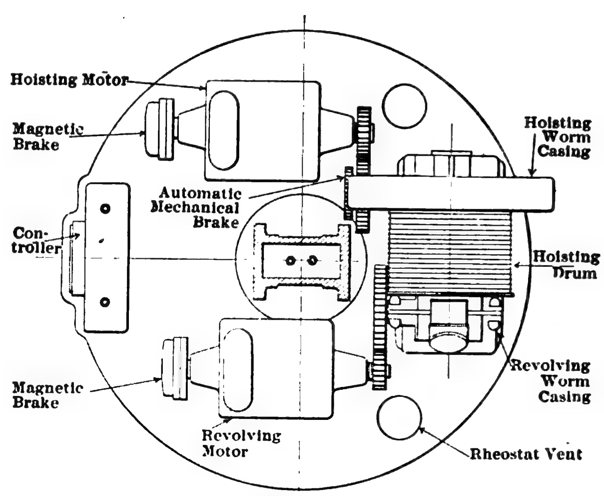

FIG. 6.—PLAN OF BOAT CRANE.

The contacts on the controller are so arranged that the armature of the motor is connected in parallel with a part or all of the rheostats, except in the full-speed positions. This arrangement has especial advantages in lowering by giving gradual increases of speed for the various steps and making very small movements of the load possible. When throwing the controller to the "off" position a temporary stop is provided at the first speed position, as at this point the armature is

short-circuited and the magnetic brake set, thereby assisting the mechanical brake to make a quick stop.

A service test of the complete crane, alternating with the full load and empty hook at full speed for one hour, is required.

With the mechanical parts properly fitted a 16-ton load may be moved a distance of 1/8 in. and a total gearing efficiency of 65 per cent may be obtained.

Deck Winches: For use in coaling ships and other purposes, a number of electrically operated deck winches are furnished.

An inclosed series or compound motor, through a pair of spur gears, drives a shaft, on each end of which is secured a winch head, the motor shaft being fitted with a foot-operated band brake. In one form of winch that is considered quite satisfactory a large casting serves as foundation for the motor and controller, bearings for the winch-head shaft and inclosing spaces for the gears and rheostats, the latter being provided with ventilation.

The controller is of the single-cylinder type, designed for operating in one direction. A reversing switch is provided in case it is desired to operate in the opposite direc-

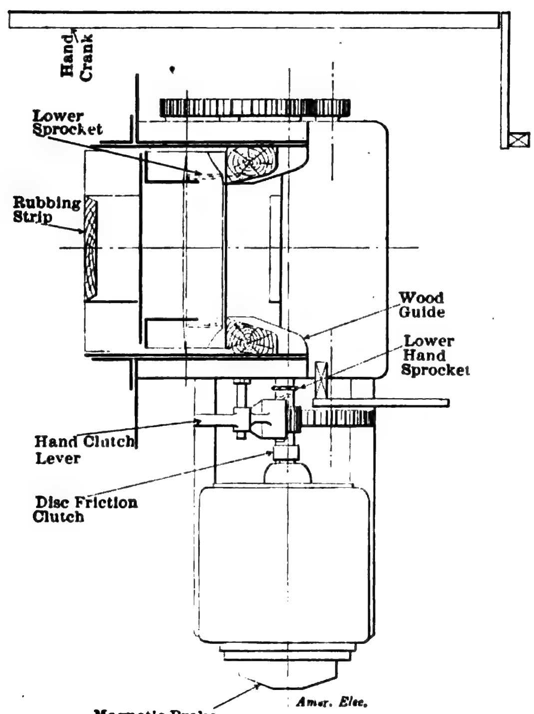

FIG. 8.—PLAN OF CHAIN HOIST GEARING.

tion, and the circuit breaker is mounted inside of the controller case. The motor is operated on plain rheostatic control.

The winches are designed to hoist 2,200 pounds at 300 feet per minute, the rope being led to the winch head through pulley blocks, located to give as direct a lead as possible, and a service test of 1/2 hour at full load and full speed is required.

The winches located on the main deck are also fitted with a compound gear, designed for hoisting 22,000 pounds at 30 feet per minute, which may be thrown in by means of clutches in case it is desired to use the winches for hoisting anchors or other heavy purposes. A total gearing efficiency of 70 per cent may be obtained, which includes the loss in friction of the pulley blocks.

Ammunition Hoists: For hoisting the ammunition from the magazines, electrically operated ammunition hoists are used. These are of three general types: turret hoists, chain hoists and whip hoists.

Turret Hoists: The turret hoists consist of a car with compartments for the necessary shell and powder charge for one fire of the gun and runs on a structural steel track from the handling room to the loading position of the gun.

An inclosed, shunt-wound motor drives

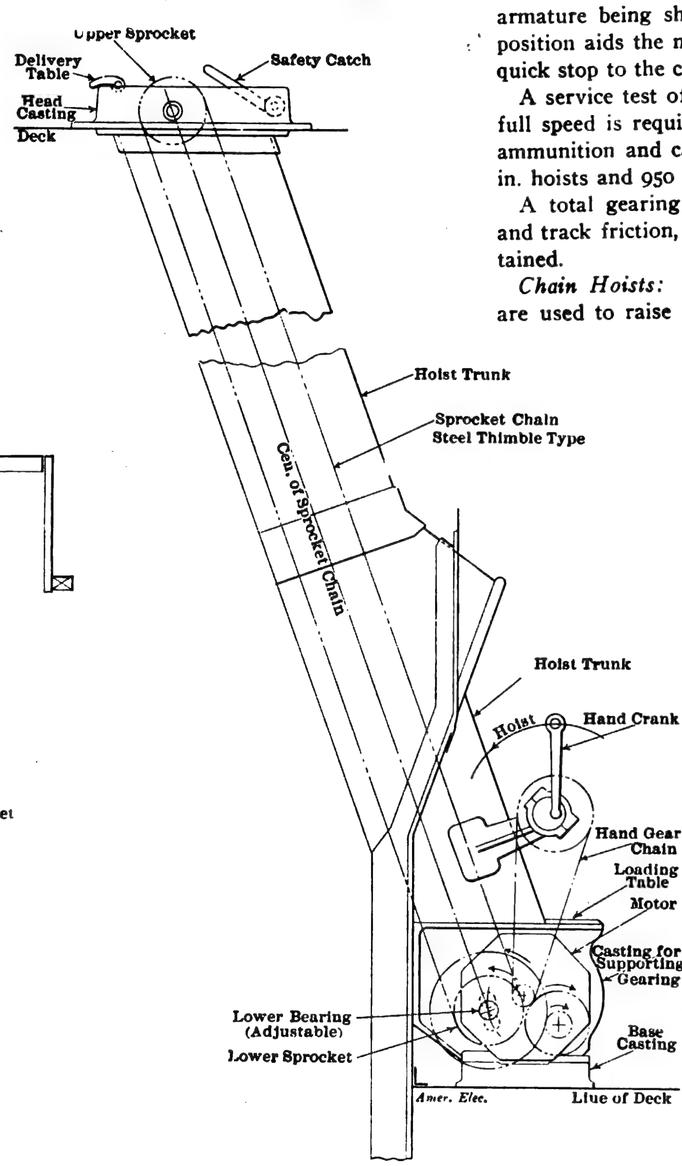

FIG. 7.—ARRANGEMENT OF CHAIN AMMUNITION HOIST.

the drum shaft through a pair of spur gears. One end of a steel wire rope is fastened to the drum, and the other end is fastened to the car, the path of the rope being guided by properly located sheaves. The controller, rheostats, circuit breaker and line switch are located near the breech of the gun, where the operator may be in full view of the car as it passes up and down the track. The motor, as well as the motor for elevating the gun, is located in the pan of the turret or in the central girder.

The motor shaft is fitted with a magnetic disc brake, which sets at the "off" position of the controller and is of sufficient power to hold the full load. The car is fitted with a safety device which will grip the track and prevent an accident should the rope break.

For hoisting, the motor operates on plain rheostatic control. For lowering, the rheostat is thrown directly across the line and at the intermediate-speed positions is gradually paralleled with the armature, which is short-circuited at the "off" position, until at the full-speed position the rheostat is in parallel with the armature. By this means the motor will take current when lowering light loads and will act as a generator sending current through the resistance when lowering heavy loads that overhaul. The armature being short circuited at the "off" position aids the magnetic brake in giving a quick stop to the car and holding the load.

A service test of 1/2 hour at full load and full speed is required. The total weight of ammunition and car is 2,970 pounds for 12-in. hoists and 950 pounds for 8-in. hoists.

A total gearing efficiency, including rope and track friction, of 65 per cent may be obtained.

Chain Hoists: Chain ammunition hoists are used to raise the ammunition from the handling rooms and passages to the vicinity of the small guns, a typical arrangement being shown in Figs. 7 and 8.

An enclosed, shunt-wound motor, operating through two pairs of spur gears, drives the lower sprocket shaft, the sprockets being keyed on. The bearings for this shaft are adjustable to take up the sag in the chain due to wear. Endless chains of the steel thimble type pass over these sprockets to two similar ones which run loose on short shafts at the head of the hoist. The ammunition is placed on carriages which are secured between these chains at regular intervals.

The hoist trunk is built of structural steel and is of sufficient section to allow the ammunition to pass up and down freely. The head of the hoist is provided with a delivery table and safety catch to prevent a charge from slipping back into the hoist.

The hoists are designed for continuous running at a constant speed, the motor being operated through a controlling panel. The end of the motor shaft is fitted with a magnetic brake of the cone type to prevent a charge from dropping should the power fail while operating the hoist.

The motor pinion is fitted with a friction slip clutch of the disc type, which is set to act when the power required by the hoist is excessive due to jamming of the charge in the trunk or other causes. A hand gear is provided for use when the motor is inoperative for any cause. The complete lower gear

is assembled on the base casting and fitted in the ship after the trunk is completed. A service test of two hours at no load is required; also to hoist a limited number of dummy charges of ammunition. The ammunition hoisted weighs from 73 to 134 pounds and the average chain speed is about 90 feet per minute. A gearing efficiency of 70 per cent may be obtained.

Whip Hoists: Whip hoists are used to raise the ammunition from the weather deck, where it is delivered by chain hoists to the small guns located in the military tops on the masts.

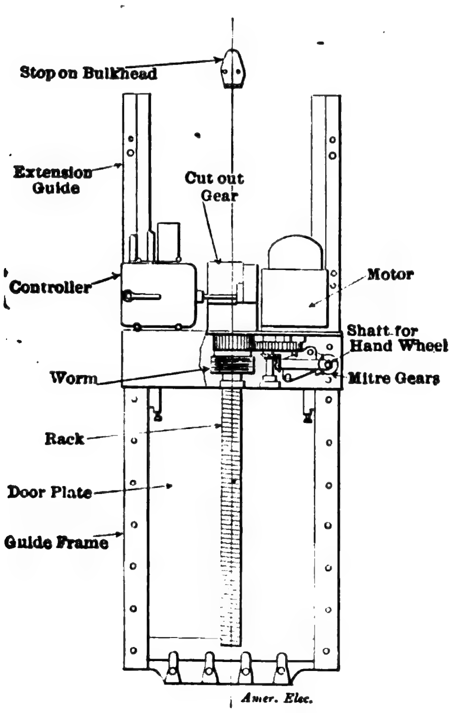

FIG. 10.—ARRANGEMENT OF POWER DOOR.

An inclosed, shunt-wound motor drives the drum shaft through a pair of spur gears. The rope leads through guide sheaves over a sheave on a davit at the point of delivery, with one end fastened to the drum and the other end fitted with a hook. A hollow base casting supports the motor and controller, the circuit breaker and rheostat being mounted in the hollow space.

The motor shaft is fitted with a magnetic cone brake and the speed control is similar to that for the turret hoists.

The rope speed is about 240 feet per minute. A service test of one hour, alternating with the full load and empty hook, is required. A gearing efficiency, including rope friction on the sheaves, of 60 per cent may be obtained.

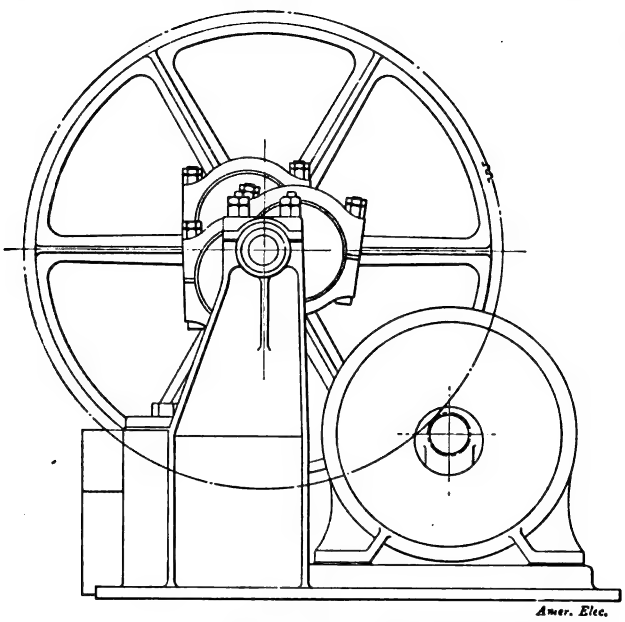

FIG. 9.—ARRANGEMENT OF ELECTRIC PUMP.

Pumps: Electrically operated pumps are used for the drainage system and fresh-water system. The pumps for the drainage system are of the centrifugal type, direct driven at constant speed by an inclosed, shunt-wound motor, operated through a controlling panel.

The tanks for storing fresh water for the ship are usually located in the hold, with a reservoir tank on the bridge deck. The water is circulated through the system of piping and supplied to the reservoir tank by electrically operated pumps. A type of pump that has given very good satisfaction in service is shown in Fig. 9. It is of the three-plunger type with spring valves, the suction and discharge valves operating on the same spindle, all parts being made of gun metal or phosphor bronze. The pump is driven at constant speed through a pair of spur gears by an inclosed, shunt-wound motor, operated through a controlling panel. An efficiency of about 45 per cent, including gears, pump and friction of piping, may be obtained.

The required service test under normal working conditions consists of 8 hours for the drainage pumps and 2 hours for the fresh-water pumps.

Power Doors: The more important hatches in the protective deck and the doors through the principal water-tight bulkheads below the protective deck are operated by power. The doors are of the vertical sliding type or horizontal sliding type, as local conditions require. An arrangement of a vertical sliding door is shown in Fig. 10. An inclosed, compound-wound motor drives a worm through two pair of spur gears. The worm engages a rack on the door, thereby making the movement of the door positive in either direction. A hand gear connection is provided in case the motor becomes inoperative.

The door operates like an ordinary gate valve, water-tightness being secured when the door is fully closed by wedges on the door plate setting up against rollers in the door frame.

The motor is operated through a controller limit switch without resistance. The cylinder is controlled by a spring so that the door may be stopped at any position by simply releasing the handle. The cylinder shaft is connected to a cut-out gear that is fitted on the worm shaft so that when the door reaches its limit of travel in either direction, or strikes an obstruction, the controller will operate and shut off the power from the motor.

The entire system of doors and hatches is arranged to be operated from the pilot house by an "emergency station," which, when once started, automatically closes the circuit of the solenoid on top of the controller. This solenoid operates a pair of contacts on the controller so as to close the door. The "emergency station" is constructed so as to start the doors at intervals of three seconds, thereby avoiding a sudden rush of current in the feeders. Should a door be closing from the "emergency," it may be opened in the regular manner by operating its individual controller handle in the regular way. When the handle is released the door will continue to close from the "emergency."

When the door is fully closed and locked a button on the door plate engages a contact box on the door frame, closing a secondary circuit, which lights a lamp in the "emergency station" so that the commander of the ship may know the position of all of the doors at any instant.

Miscellaneous: Where the ammunition hoist is located at some distance from the magazine the ammunition is transported along the passage by endless-chain conveyors which are driven at constant speed through gearing by an inclosed, shunt-wound motor operated through a controlling panel.

The power for the laundry machinery is taken from a countershaft which is driven at constant speed through a pair of spur gears by an inclosed, shunt-wound motor, operated through a controlling panel. The power for driving the machinery in the work shop is furnished in the same manner as for the laundry machinery. The air compressors for supplying air for torpedo tubes, smoke ejectors for the turret guns and pneumatic tools are driven at constant speed by inclosed, shunt-wound motors operated through controlling panels.

STREET LIGHTING BY INCANDESCENT LAMPS.

BY JOHN HOWATT.

The field of lighting streets electrically has generally been conceded to the arc lamp, but there are cases where an incandescent lighting system might be preferable. The arc lamp as manufactured at present concentrates a great deal of light in one place. In outlying districts of a city or in the residential portion of a village an arc lamp gives more light than is absolutely necessary and more than can be afforded; or, if they be used, they must be installed so far apart that the illumination midway between the lamps is very poor. If the streets are crooked or heavily shaded by trees, the distribution of light will be still worse.

The incandescent lamp lends itself readily

to division into small units, so that for illuminating crooked or shaded streets it is especially applicable. In outlying districts, where one arc lamp every second block is all that can be afforded, the same watt consumption divided up into eight incandescent lamps distributed four to the block gives a more satisfactory illumination.

The arc lamp has also several objectionable mechanical features about it from which the incandescent lamp is free. The incandescent lamp is shadowless, it has a better appearance in the daytime than the arc lamp, and there is no cost of trimming. On the other hand, with the incandescent lamp there is always a greater expense for

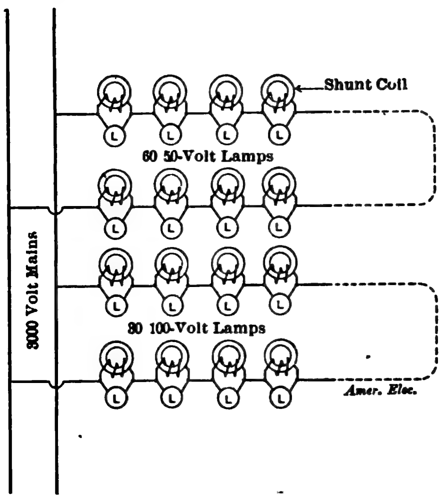

FIG. I.—WESTINGHOUSE SYSTEM OF SERIES INCANDESCENT LIGHTING.

repairs, and the efficiency is low compared with that of the arc lamp.

There are two general systems used in operating incandescent lamps for street lighting. These are the multiple system and the series system. The multiple system is used chiefly in small towns where a special generator or transformer could not be installed. The lamps used are the ordinary multiple lamp, generally of 16 or 32 candle-power. In one town of 6,000 inhabitants, which was brought to the writer's notice, the entire residential portion is lighted by multiple incandescent lamps on 110-220-volt, direct-current, three-wire circuits. Sixteen-c.p. lamps are used, two at each corner placed diagonally across the street, and three more spaced evenly along the block, two being on one side of the street and one on the other. This makes an average of five 16-c.p. lamps per block, or a consumption of about 275 watts per block. While the illumination is not brilliant, it is very uniformly distributed and is sufficient for all except the business streets. The great cost of feeders for such a system, however, prevents its adoption on a large scale.

In some other instances where multiple lamps are used, current is taken from high-potential mains through step-down transformers distributed over the area to be lighted. Each transformer supplies the lights of, say, one block at 110 volts. In this system the lamps are often clustered into groups of three or five. Sixteen-c.p. lamps should be used in preference to 32-c.p. lamps, as the latter lamp is just as liable to be broken as the former, and the cost of repair is materially less in the first case.

The series system of operating incandescent lamps has a much wider application than the multiple system. This is solely because of the great saving in copper this system affords over the multiple system. The lamps themselves are not as economical. The manufacture of a filament to carry 3½ amperes has not yet reached the perfection it has in the manufacture of a filament to carry ½ ampere. Then, too, the complications and imperfections of a cut-out device for each lamp and a regulator for each circuit are introduced in the series system.

There are two main systems of series incandescent lighting in use at the present time. In one a string of lamps is operated in series in a loop across high-voltage, constant-potential mains. In the other a circuit of lamps in series is operated by a constant-current transformer or regulator. There was at one time another system which had a constant-current generator for each lamp circuit, but this has gone out of use.

The first-mentioned series system of incandescent lighting is the one brought out by the Westinghouse Electric & Manufacturing Company. Fig. 1 shows the general arrangement. Either 50 or 100-volt lamps are used, taking about 3 and 1½ amperes, respectively, for a 50-c.p lamp. These higher voltage lamps are preferable in most cases because a lamp with a short, thick filament for, say, 25 volts, cannot be made to operate as economically as one with a longer, thin filament for 50 or 100 volts. On the other hand, the number of lamps in series in a circuit can be greater with the lower-voltage lamps, so that sometimes in long circuits they have to be used.

One of the most important features of any series incandescent lighting system is the means providing a safe path around a lamp in case a filament is broken or burns out. As all the lamps are in series, if one

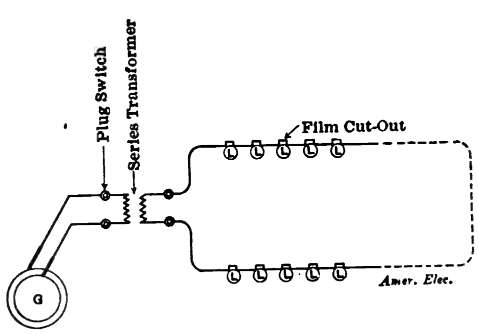

FIG. 2.—GENERAL ELECTRIC SYSTEM OF SERIES INCANDESCENT LIGHTING.

of them should burn out and no other path were provided for the current the voltage about the damaged lamp would rise, destroying the lamp base and putting out all the other lamps in the circuit.

In the Westinghouse system a shunt coil is connected across each lamp to protect it in such an emergency. The device consists of a coil wound on a laminated iron core, magnetized nearly to saturation. It is connected directly across the terminals of the lamp, and under normal working conditions takes but little current. When a filament breaks, however, all the current is forced through the shunt coil, and owing to the high saturation of the core the counter e.m.f. of the coil rises but little above the voltage of the lamp which it displaces. Thus the operation of the other lamps in the circuit is not affected, and the base of the injured lamp is protected from damage by excessive voltage.

The system is one that commends itself for its simplicity and certainty of action. It has the further advantage that the lighting circuits do not all have to come back to the power house, and as no special equipment is necessary, a station already furnishing high-voltage, alternating current can undertake this method of street lighting at a small initial outlay. This system has the objectionable feature that the shunt coil causes a constant loss on the circuit, and when the shunt coils burn out they are rather expensive to repair.

The system which includes a constant-current transformer for each lamp circuit is the one brought out by the General Electric Company. A transformer is used which is the same as the well-known type used for series, alternating-current, arc lighting. Fig. 2 shows a diagram of the arrangement. The transformer is adjusted by counter-weights to give a certain fixed current and regulates for this value very closely. Lamps requiring current ranging from 1.75 amperes to 5 amperes are used. Of course, for any one circuit lamps must be selected which take the same current. On the transformer primary voltages of 1,000 or 2,000 volts are used, while the secondary voltage may range from 1,000 to 6,000 volts. This permits a great range in the number of lamps that can be connected in series in a circuit. Each circuit must come back to the station and is complete in itself through the switchboard and transformer. A film cut-out, located in the base of each lamp, protects the lamp and closes the circuit if any of the filaments burns out. The essential part of this cut-out is a thin insulating film which normally separates the two lamp terminals. If a filament breaks, the voltage across the lamp terminals rises a certain amount until it punctures the film and short-circuits the lamp, thus protecting it, and also keeping the circuit through the other lamps closed. There is no lost energy with this device as there is with the shunt coil, but the system is a more expensive one to install and is not as flexible as the system first described.

Heat Lost by Radiation from a Bare Pipe.—According to a contemporary, a square foot of uncovered pipe, filled with steam at 100 lb. pressure, will radiate and dissipate in a year the heat obtained by the economic combustion of 398 lbs. of coal. Thus, 10 square feet of bare pipe corresponds approximately to the waste of two tons of coal per annum.

A NOVEL SYSTEM OF EMERGENCY LIGHTING.

BY OUR BERLIN CORRESPONDENT.

A system of emergency lighting for use in theatres and other buildings has been devised by Prof. Hochenegg, as shown diagrammatically by Fig. 1 herewith. For simplicity's sake only one group has been represented in the diagram with two individual devices. Each of these includes a direct-current relay, the armature of which carries a metal bow, which, when the armature is released, completes the circuit between the emergency lamp and its battery consisting of three cells connected in series. In place of one emergency lamp two lamps in parallel could be used so that a sufficient amount of light will be obtained in the event of one lamp failing. These lamps are designed for an e.m.f. of 6 volts and consume about one ampere. The relays, batteries, etc., are all connected in series by the two heavy outer wires which terminate in a double-pole switch. If the levers of the latter are placed on *a*, current from the mains will traverse the conductors, relays and batteries of the emergency apparatus. So long as the intensity of the current in each group is above one-half ampere the armatures of the relays are held out of contact with the emergency lamp circuits. As soon, however, as the current falls below this amount, the relay armatures drop, closing the circuits of the emergency lamps. In order to again lift the relay armatures it is necessary to bring the current up temporarily to at least 2.5 amperes.

The current is controlled by a rheostat which is graduated so that the current in a given group of lamps cannot reach the limit of 2.5 amperes per group, so long as the lever does not impinge against the spiral spring. A current in excess of 2 amperes can only be obtained by moving the lever against the pressure of the spiral spring, thus lowering the resistance. As soon, however, as the lever is released the spiral spring throws it back to its contact limit, thus causing the current in each group to drop below 2.5 amperes.

It is evident from the foregoing that the lamps of a given group are readily lighted by interrupting for a short time the circuit of the group in question at any given point. This is effected by interrupters placed at convenient places in the theatre. In order to light the emergency lamps of all the groups simultaneously the current supplied from the mains should be interrupted temporarily or permanently by moving the switch from the contacts *a*. As a possible disturbance in the mains would result in the emergency system being switched out of circuit, the switch could be placed in the central position, *b*, during the time the emergency lamps are operated. The control lamp is then lighted as long as the switch is in this position.

In order to cut the lighting system out of circuit, a sufficiently strong current impulse for each group of lamps should be thrown on the conductors, thus attracting the relay armature and cutting out the emergency lights. This result is obtained by placing the switch on the contacts, *a*, and throwing over the lever of the rheostat against the spiral spring until the current intensity of 2.5 amperes or more is indicated on the ammeter *A*. The batteries for the emergency lights are thus charged automatically, the current being adjusted by means of the rheostat. The second resistance shown is intended for allowing the lighting system to be switched off in case of failure of the circuit. The following advantages are claimed for the system: Each individual emergency lamp, having its own battery, is self-contained and independent of the main lighting system; all the emergency lamps can be inserted simultaneously from one point in the event of a sudden outbreak of fire, while several groups of lamps can be put in circuit independently by means of special switches; any disturbance in the conductor system, due to fire, water, etc., will cause the emergency lights to operate; the total number of emergency lamps can be switched out from one point and the recharging of the batteries occurs automatically as soon as the lamps are switched out; the batteries need not be removed.

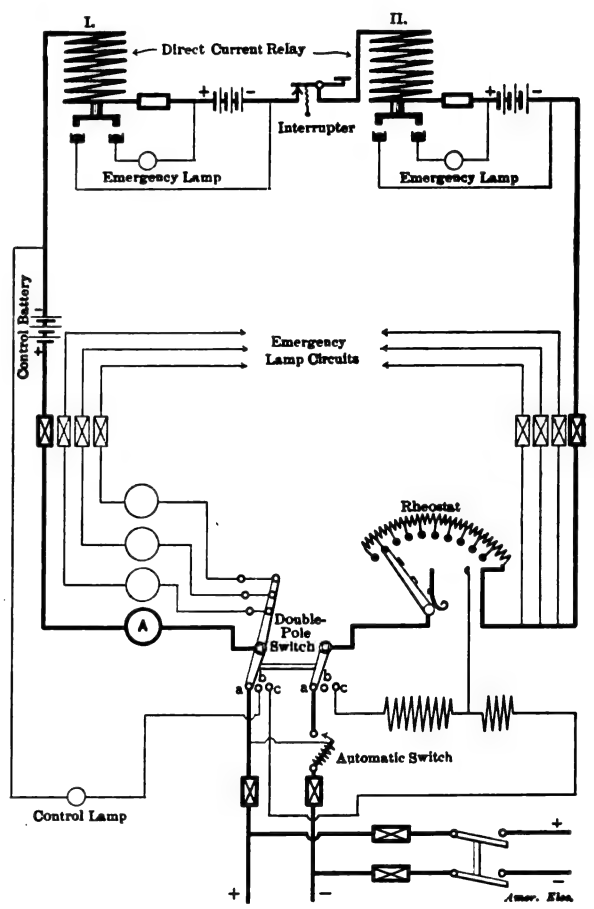

FIG. 1.—SYSTEM OF EMERGENCY LIGHTING.

AUTOMATIC BLOCK SIGNALS.

BY RALPH SCOTT.

The Interlocking Machine.

An interlocking machine which conforms to standard requirements is shown in Fig. 73, which also gives a rear view of the apparatus and the relative relation of the various parts with the position of the locking mechanism. This interlocking machine consists essentially of the case *H*, the controller *C*, the fuse and terminal board *A*, the magnets *I* and *S*, the locking arrangements *G* and the various levers *D*, with their guides, *E*. The frame work is mounted upon one or more pedestals, which support the whole. Machines which are constructed of more than three half sections, usually employ more than one pedestal for supporting the mechanism. Interlocking machines which have a great amount of locking are arranged in what is known as a double tier, from the fact of the locking plates being arranged in two rows, the projecting handles for each row being turned in opposite directions. The fuse board *a*, which forms also the place at which all the connections are made, contains all the circuits with their proper fuses and facilities for making rapid connections.

This terminal board consists of a slate slab across the entire length of which three bus bars run. This slate slab is made in sectional form which pieces altogether along the entire length of the machine. The lower bar is the operating bus bar, all signals being connected to this bus. The middle is the indication bus bar, to which all signals and switches are connected, and the upper is the operating bus bar, all switches being connected to this bus.

The wires coming from the magnets, batteries, circuit controllers, etc., are connected to binding posts mounted upon the slate in the order shown. All fuses and terminals which are connected directly by any lever are placed directly beneath this lever. The reason for such an arrangement is to facilitate interconnection and disconnection either for permanent or for testing purposes. All the connecting wires pass from the various controllers to this terminal board, these being made up into regular sets which are tapped together in a systematic manner. The case *H* is for the purpose of enclosing the levers and controllers, the terminal board and locking mechanism being exposed.

To render all parts accessible for inspection or repair, glass doors are provided in the top of the case. Locking is effected, as already stated, by the tappet bars, guides and dogs, the arrangement of these tappet bars being such as to effect the required cross locking.

Sliding in the guide *E* is the lever *D*, which is held in place by the caps *F* and by the continuous lever guides. This lever has machined within it the cam slot *U*, which gives the desired motion to the tappet bar *V*. This tappet bar, as we have already stated, is shown in its various positions by the circles, which are numbered 1 to 5, the

cam slot representing the exact position of the tappet bar which corresponds with the similarly numbered positions of A'. This sliding contact is connected to the lever by means of the rod w, any movement of the levers thus causing a corresponding movement of this rod, which in the various

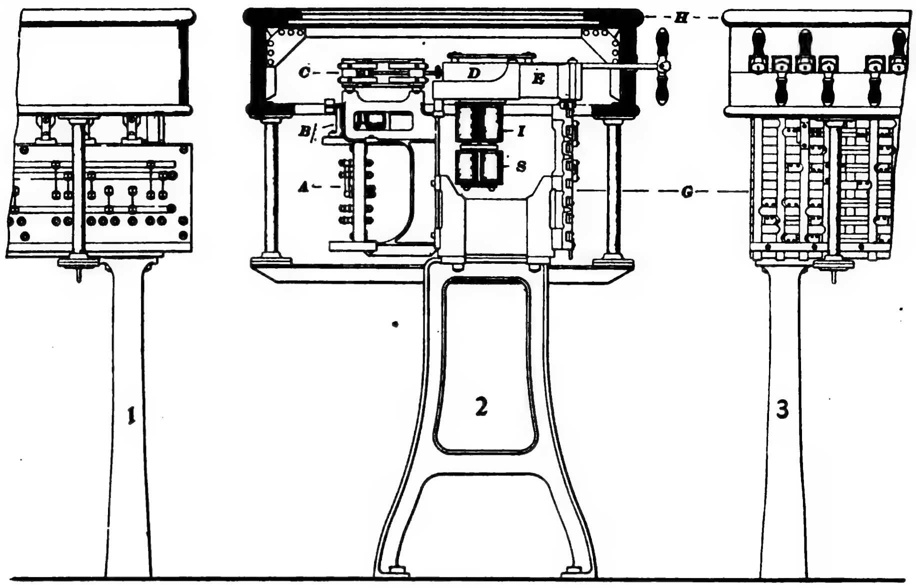

FIG. 73.

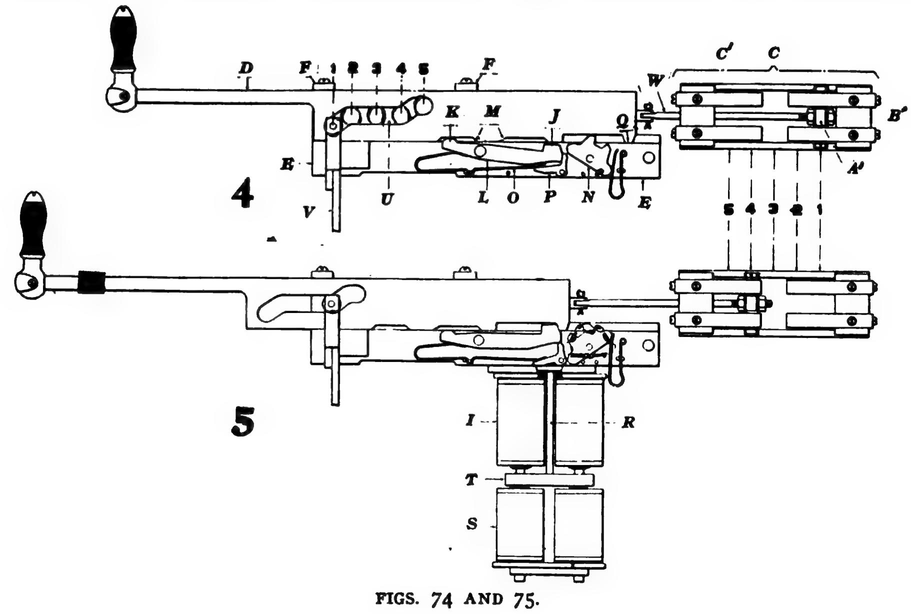
positions causes it to assume the positions 1 to 5.

To prevent confusion, the handles are usually of different colors. When two switches are to be operated simultaneously or are solidly connected, a short lever is used for imparting the desired motion. This short lever is not provided with a cam slot, the locking being effected by the long lever. The short lever, however, has its guide controllers and magnets. Fastened to the frame work in the manner shown is



FIGS. 74 AND 75.

the lever guide E. Mounted upon this guide are the springs, dog, cam, latch, etc., which are shown in Figs. 74 and 75, and rigidly held in place by the adjacent lever guide. Secured to the lower surface of this lever guide are the magnets I and S, S being the safety magnet which is used only on the switch levers, and I the indicating magnet common to all the levers. The brushes C' and B', which are connected to the controller C in the manner shown are fastened to the fixed insulating block fastened at the ends of the controller, the sliding contact C' being connected to the rod W. The contact arrangement and circuit relation of these brushes are shown diagrammatically in Fig. 72. According to the various positions of A' they will be thereafter referred to as 1, 2, 3, 4 and 5, depending on the respective positions of the lever.

In connection with all switch levers is an indication selector B, which is operated by the working current, and connected in such a manner that it is moved in one direction with a certain direction of current and in the opposite direction with a reverse direction of current. Either of these may be the normal position. A function of this selector is to close the indication circuit, which has the correct relation to the position of the lever, and which leaves the other circuit opened at the same time.

By following up the changes which occur when a lever is moved through a complete stroke, it is possible to understand the methods employed in preventing the lever from passing from the beginning to the entire completion of this stroke unless everything is in the proper shape to prevent the conflicting of levers or routes.

The motion from the positions 1 to 5 is accompanied by an unlocking of all the levers which conflict, providing, as said before, everything is in the proper condition to admit of such unlocking. In the switch lever shown in Fig. 74, this lever is in the full normal position, while in Fig. 75 the same lever is in the reverse control, an indication position, these positions showing the operation, functions and connection of the various intercepting devices employed for preventing the lever from moving to the full position unless all these accessories are in the proper condition to warrant such movement. When the lever passes from the position 1 to 2, the tappet bar V is raised, which locks every conflicting lever and causes the projection M on the lever D to come in contact with the projection K provided on the latch L, thereby causing the latter to assume the position shown in Fig. 74, such position bringing the projection J directly in front of the tooth Q, as shown in Fig. 75. When the lever passes from position 2 to 3, the tooth Q becomes engaged with a similar projection on the cam M, which causes it to revolve in a horizontal position.

In passing from 3 to 4 the cam N revolves and finally assumes a position shown by the full lines in this figure, the lever being stopped at the position 4 by the tooth Q, which comes in contact with the projection J. At the same time A', having come in contact with the stationary brushes C', closes the battery circuit, which sends current to the motor and causes the switch to be thrown to the correct position, and locked in this position, the indication current resulting on the change in connections being sent through the magnet I and the lifting armature F, thus causing the plunger R to strike the dog P, and throw it from under the latch L. This latch being thus released, drops to its lower position, and thus permits the lever to move from 4 to 5, which completes the stroke; and, by lifting the tappet bar V, unlocks the levers which do not conflict with this new position.

In passing from the reverse to the normal position, the action is similar to the above, with the exception that on the reverse stroke, when the contact A' is in the position 4, the current passes to the magnets I, from the battery, and thus gives an artificial indication, which allows the lever to be passed to the position 5, as already explained. All the signal levers operate in the same manner. Since the function of the safety magnet S has already been explained, its use will be at once evident. The advantages of the operation above defined cause an unreliable indication to be almost impossible for the following reasons: (a) On account of the fact that there is effected both the mechanical and electrical locking of the lever D, this latter could not be moved to any position if any conflicting routes had been set up. (b) If

the lever has been once moved to or beyond the position 3, it is impossible to move beyond the position 4 or backward to position 2 without an indication, which latter cannot be given unless the locking is in a position which corresponds with the position of the lever. (c) Since the lever *D* is free to move, and is forced to stop at the position 4, and thereby prevented from passing to the position 5 without an indication being received, no conflicting levers can be unlocked, which proves positively that the switch has been moved to, and locked in the position which corresponds to the position of the lever.

In Fig. 76 is shown the complete switch and lock movement, which is that provided for a left-hand switch. This movement consists essentially of the motor, switch machine, detector bar and connections. The motor, which is shown at *D*, is of a construction which prevents any weather conditions from being deleterious to the motor mechanism, this being effected by providing the cover with a rubber gasket, the armature shaft itself passing through an adjustable stuffing box. When the cover is removed, the entire mechanism is exposed for inspection.

The motors are so constructed that the power which they are capable of exerting may be varied, by changing the armature and field connections. The switch machine consists essentially of the connecting shaft *A*, lock movement *K*, driving rod *L*, pole changer *E*, gear frame *O*, and the cover, which is so designed as to keep out all snow and rain from the moving system. A flexible universal joint connects the connecting shaft *A* with the motor shaft. The gear frame mechanism *O* performs two functions: first, reduces the speed of the motor and consequently increases the power applied at the switch movement, which is necessary for both this switch movement and detector bar movement; and second, to cut off the motor when the switch has moved to its proper position—that is, has entirely completely its stroke. The main gear shaft has mounted upon it a cam, a clutch shifter, a gear and a pair of clutches, which latter effect the disengagement of the motor from the switch mechanism.

The gear and clutches are both mounted on the shaft, directly connected to the motor armature. The clutches, although free to move parallel to the shaft, are keyed to the latter and when moved to the position which is controlled by the shifter are forced against the gear by springs. Except when one clutch is engaged with another, the gear is loose upon the shaft, the clutches being connected to the gearing, which latter is connected to the motor.

The completion of the stroke causes the clutch to move sideways, this being effected by the cam operating through the shifter, which disengages the motor and allows the armature to maintain rotation by the momentum which has been given to it. The counter e.m.f. set up by the motor during its rotation is utilized to give an indication through the indication magnet, which was explained diagrammatically in Fig. 72. The pin *H* effects the movement of the switch detector bar and lock plunger, this pin being fastened on the main gear, connected directly to the lock movement by the rod *L*, and to the switch by an intermittent motion when engaged with the crank cam *P*.

The lock plunger, detector bar and pole changer are operated through the interposition of the lock movement *K*. The link *N* transmits motion to the crank *S* by the rod *L* and to the lock plunger by the link *I*, the plunger and detector bar being both driven by the cam crank. A movement of the former would be impossible if a train be on the track in the near vicinity of the switch, since the prevention of motion of the detector bar prevents any movement of the plunger.

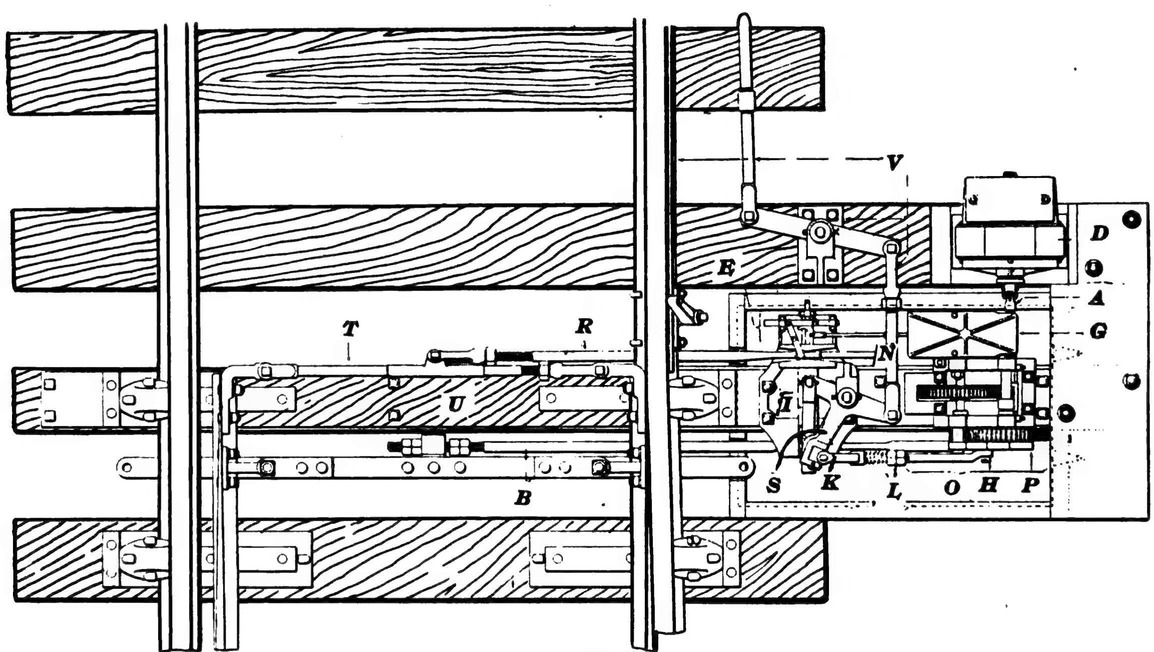


FIG. 76.

Therefore, the switch cannot be thrown under these conditions. By means of the pole changer movement, *E*, after the lock plunger in returning has passed entirely through the hole in the lock rod, *R*, motion is imparted to the pole changer, *G*. The pole changer, *G*, by the action of two pins on the lock rod, *R*, causes this pole changer to be thrown in one direction when the switch has been thrown to the normal position, and in the other direction when the switch has passed to the reverse position. This movement of the pole changer cuts the working current from the motor, reverses the armature connections and finally completes the indication circuit. These operations and the switch connections have been described in Fig. 72. The pole changer is either operated mechanically or electrically, the latter being effected by the magnets in the manner which we have already explained. The circuit breaker, which cuts off current from the magnets when the switch has reached its full normal or reverse position, has a revolving character, the entire switch being enclosed in a cast iron case.

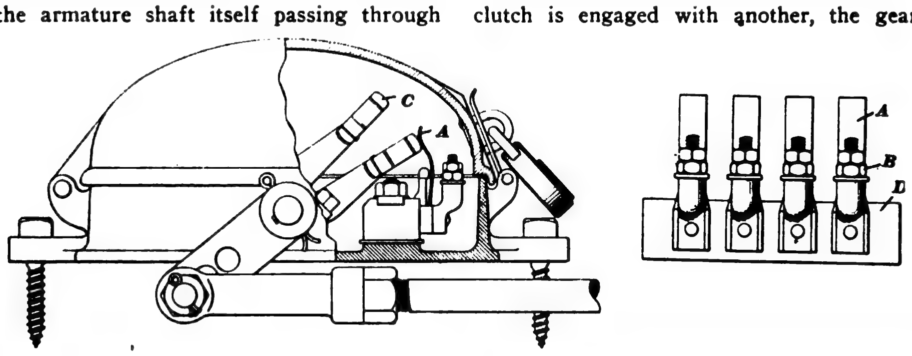

FIG. 77.

This switch is illustrated in Fig. 77 and consists of the insulated contact bars *C* which make connection in both positions of the stroke by the stationary contact pieces *A*, fastened upon an insulating block *D*, to which connection may be made by the posts *B*, the whole being enclosed in a suitable case which is padlocked to prevent tampering. Securely bolted and braced to the rigid tie plate *U*, which is placed above and upon the face of the tie, is the gear frame lock movement and rails, this plate

thus maintaining all the parts at their proper distance from one another.

The lock and front rods are shown respectively at *B*, *T* and *R*, the former and latter being bolted to the lock plunger, the detector bar being shown at *V*. Taking the switch movement as a whole, we have the following operation: Current having

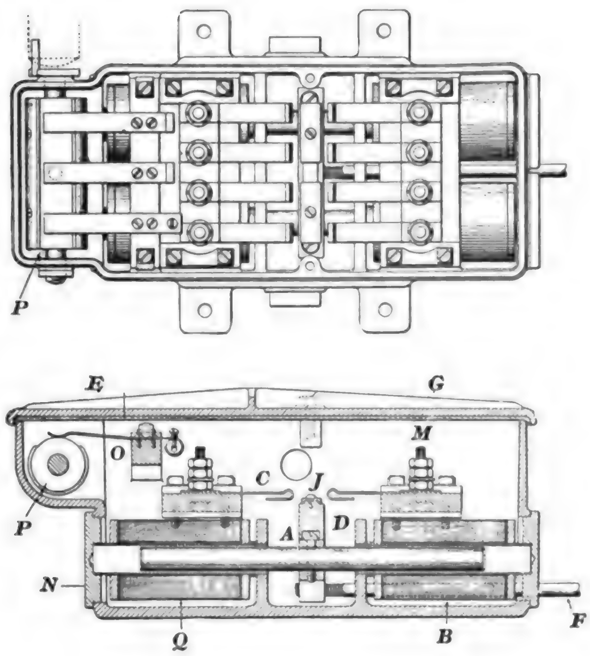

FIG. 78.

been delivered to the motor in the manner shown in Fig. 72, the latter is set in motion, and, through the interposition of the train of gearing, causes the main gear with the pin above to pass through a complete revolution. At about one-third of this revolution the lock bolt is withdrawn, the detector bar being at the same time moved to its upper position.

When this has been accomplished, the pin mentioned above, by coming in contact with one end of the crank cam *P*, throws the switch during the next one-third of the revolution. The lock rod is returned to its original position, and the detector bar lowered during the final one-third of the revotution. When the lock plunger has passed through the lock rod, the pole changer is thrown, the motor at the same time being disconnected and disengaged as explained above, thus resulting in an indication through the indication magnet as already shown.

The detector bars are generally fifty feet long and, consequently, require a powerful force to move them. In the manner explained above, it is impossible for the switch to be thrown if the train be within fifty feet of the switch point.

In Fig. 72 was shown in diagrammatic form a single arm high signal. This signal includes the signal movement proper and a circuit breaker. The signal movement includes an electric motor, a train of gears, and a magnetic brake; this brake acts upon the motor armature and brings it, when necessary, to an almost immediate stop. The circuit breaker consists essentially of a frame with a suitable cover, the entire housing being fastened to the signal pole. The frame carries a set of fixed contacts, together with a sliding contact with the necessary operating mechanism. Supported within the frame are two vertical and parallel strips upon which the fixed contacts with the binding posts are mounted. The operation of this circuit breaker is as follows:

When the signal arm descends it moves a rod within the circuit-breaker downward; a spring encircling this rod is thus compressed. When the semaphore has reached the full clear position, the upper contacts are disconnected and the lower contacts connected to the fixed contacts carried on the bar. The upper contacts control the motor and brakes, the lower ones being used to complete the circuit of the distant, if such an arrangement is used. When it is desired to break the circuit of the switch mechanism by this means, an independent set of fixed and sliding contacts is provided, which open the switch circuit as soon as the semaphore starts to move to the clear position.

Taken as a whole, the operation of the signal is as follows: Current having been delivered to the signal motor by the reversal of the interlocking lever, the armature is set into rotation, and, acting through a train of gears, moves upward a chain fastened to a counter weight, which latter is connected to the signal arm by an iron rod, thus moving the latter to the clear position. When the semaphore has reached

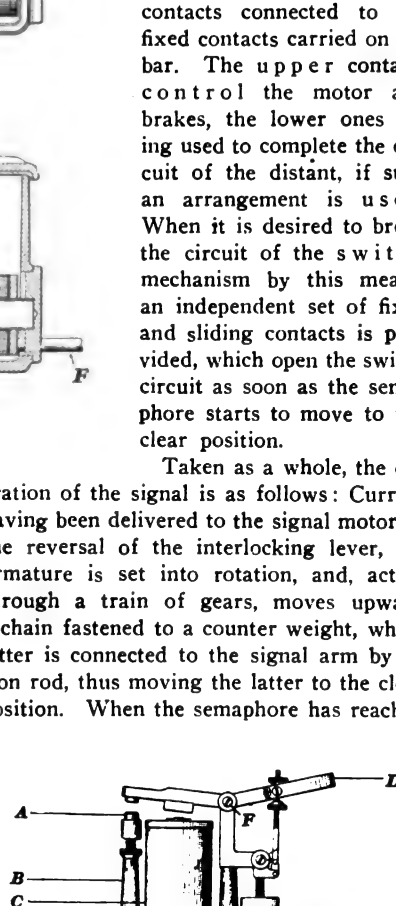

FIG. 79.

the clear position, the circuit breaker opens the lower set of contacts and closes the upper set, which latter sets the brake, and also immediately stops the motor, thus preventing the momentum of the moving system from causing a breakdown. If it is necessary to cause the signal to assume the danger position, the lever on the interlocking machine is moved to its normal position, which takes all current from the brake magnet and motor, and causes the circuit to be completed through the motor and indication magnets, which thus open the signal circuit breaker.

The motor being now free, the action of gravity on the counter weight causes the latter to fall, thus turning the motor backward and at the same time causing the semaphore to move to the danger position. At the instant that the semaphore has arrived at this position, the circuit breaker closes the indication circuit, and the motor, which by its continued revolution acts as a generator, sends current through the indication magnet and releases the lever, the diagram of the connections in this case being already explained.

If the semaphore should come against its stop position before the brake has been set, the flexible connection *D* prevents any injury being done to the mechanism. Any failure of current or electrical or mechanical connection will cause the signal to immediately assume the danger position. The same arrangement is used in two-arm and three-arm signals.

In the dwarf signal the operating means consist of a double solenoid connected to circuit breakers, these being located in the base of the signal and held in place by a frame surrounding the solenoid. When this solenoid is energized, the working coil exerts a pull of sufficient strength to move the signal to the clear position and also to compress a powerful spring which forces the arm to the danger position when the current is cut off.

The general manner of producing power for the operation of the Taylor system is by means of a storage battery, which is charged by a portable generator operated by a gasoline engine, although if it is possible to obtain commercial current at 110 volts, an electric motor is often substituted for this gasoline engine; or, a switchboard is provided which allows the battery to be charged directly from this commercial circuit, without employing either a motor, engine or generator. The voltage employed in operating switches and signal is 110, which requires that 55 cells of storage battery be used, the capacity of these cells depending entirely on the number of train and switch movements during a certain time, the battery employed being of sufficient capacity to make it unnecessary to charge them oftener than once a week. Since the electric current is used exclusively for the operation of switches and signals, it is possible to have the signal lamps thus lighted, which is a matter of great economy over ordinary oil lighting, especially if a large number of these lamps be used.

The generators employed are shunt wound, operating at 1400 r.p.m. At each signal tower from which the signals are operated by the interlocking signals, a switchboard is provided, which is of the standard form used for ordinary commercial lighting.

A reversible pole changer which is fastened to a switch machine is shown in Fig. 78. This consists of the rod *F* attached to the solenoid core *A* by the insulated piece *D*. These solenoids, *Q* and *B*, are operated by current from the switch machine motor. The insulated piece *A* carries the contact strips *J*, which make and break connection with the contact clips *C*, connected, as shown in Fig. 72, to the binding posts *M*. A circuit closer *P* in the form of a drum is operated by the movement of the switch mechanism and makes (at *F*) armature *D*, which is weighted adjustably at *G*, makes contact with the carbon contact *A*, adjustably placed on the post *B*. Where very heavy currents are to be controlled, the arrangement shown in the lower part of the figure is used. An auxiliary coil *J* in series with the contact *H*, and independent of the coil *I*, is provided. The purpose of this coil is to blow out the arc immediately when the circuit is opened at *H*.

An extensive application of the Taylor system is shown in Fig. 80, which represents the complicated arrangement of north, east, south and westbound signals on the Chicago, Rock Island and Pacific; Lake Shore and Michigan Southern; Illinois Central; and Chicago, Milwaukee and Northern Railroads, at their intersection at Sixteenth and Clark streets, Chicago, Ill. This diagram is given to show the extreme applicability and perfect protection afforded by this type of signal.

Although American railroads in general prefer the normal clear system, the reasons for this preference are not because this system has greater relative merits, but to a sort of "follow the leader" habit which seems to be established.

The fact that the initial cost of the installation of the normal clear system is greater than the normal danger system cannot be doubted or denied, but the running expense is greater in the normal clear system, because of the fact that the track battery is short circuited when the signal is at the danger position, caused by the opening of a switch, and also the signal slot magnets are normally taking current from the battery.

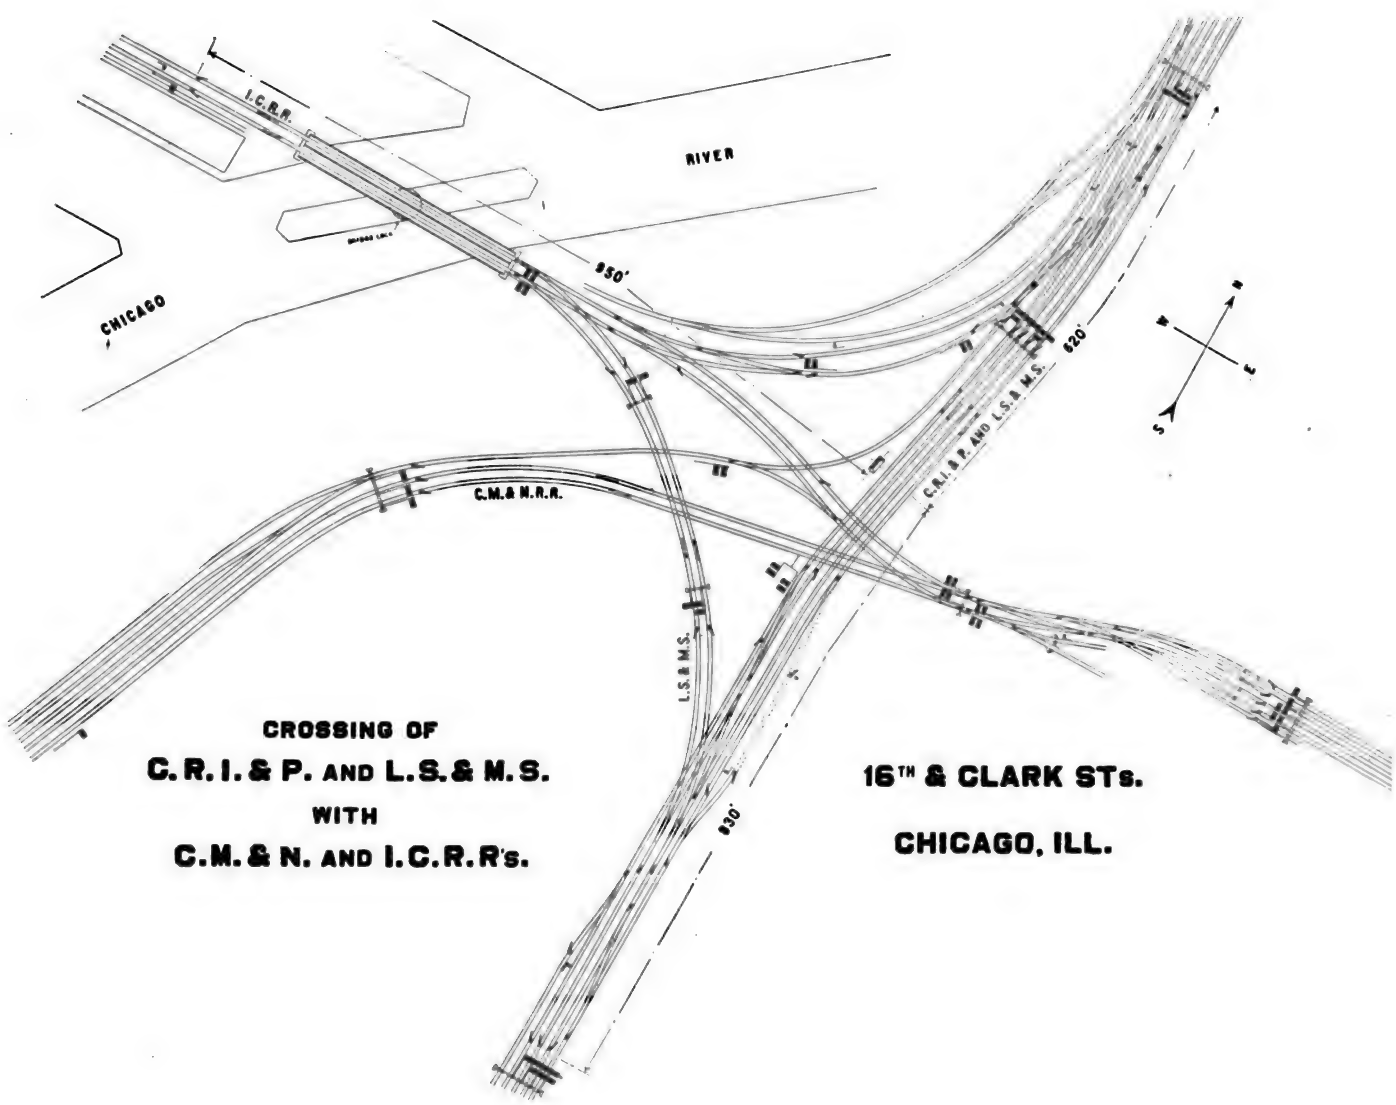

FIG. 80.

or breaks contact with the clips *O*. This mechanism is enclosed within the cast-iron box *N*, provided with the cover *G*, which is gasketed by the rubber pad *E* to prevent the admission of water or moisture.

When the Taylor signal is applied to the ordinary track relay system, a special form of track relay is necessary, which has contacts capable of making and breaking a circuit carrying a large current at 110 volts.

Such a relay is shown in Fig. 79, and consists of the electro-magnet coils *C*, connected, through the binding posts *E*, to the track in the usual manner. The pivoted

However, the following cannot be denied:

(a) THE PRIMARY OBJECT OF A SIGNAL IS PROTECTION. It is not designed to serve the purpose of an ornament.

(b) THE TENDENCY OF THE MOVING SYSTEM OF A SIGNAL IS TO REMAIN IN THE POSITION WHICH IT OCCUPIES FOR THE GREATEST LENGTH OF TIME.

(c) As far as protection is concerned, IT IS BETTER TO HOLD A TRAIN FALSELY THAN ALLOW IT TO MOVE ON WHEN A DANGEROUS CONDITION EXISTS. The importance of (C) can better be shown in answer to the question: "Which is to be preferred, a wreck or the loss of a few minutes' time?"

Abstracts from Foreign Contemporaries

Ageing Coefficient.– According to the *Elektrotechnische Zeitschrift*, the hysteresis commission of the Verband Deutscher Elektrotechniker has introduced a new term, "ageing coefficient," defined as the percentage increase of the "loss coefficient" after the material tested has been heated to 100 C. for 600 hours. The "loss coefficient" is defined as the iron losses, expressed in watts, in one kilogram of material at a flux density of 10,000 lines per square centimeter, at a frequency of 5c cycles per second and with a magnetizing current the voltage curve of which follows the sine law.

A Novel Type of Dynamo.—The Berlin correspondent of the London *Electrical Review* contributes an article on the new type of dynamo previously described in the *Elektrotechnische Zeitschrift*. The dynamo is primarily intended for train lighting. It possesses two striking characteristics: the development of an e.m.f. whose direction is independent of the direction of rotation, and the development of a current which, beyond a certain speed, remains practically constant, even though the speed be increased indefinitely. The method by which these results are obtained is evident from Fig. 1. A storage battery *Q* supplies current to the lamps when the train is at rest. This is connected to the field winding *ff* of the dynamo and produces the polarity indicated by the letters *nn* and *ss*. The main brushes *BB* are placed in a line with the pole pieces. When the train is at rest the battery is prevented from sending a current into the armature through *BB* by the action of an aluminum cell included in the circuit, which only permits a charging current to pass. The auxiliary brushes *bb*, which are at right angles to the line of the pole pieces, are short circuited. If the armature is rotated either way the short-circuit current which passes between *bb* produces a powerful cross field, indicated by the letters *NN* and *SS*. It is this cross field which acts as the main field with respect to the main brushes *BB*. Since the direction of this field will be reversed with a reversal of the direction of rotation, it follows that the polarity of the main brushes *BB* is independent of the direction of rotation. The field produced by the winding *ff* is very weak, so that no sparking difficulty is experienced with the main brushes. The charging current delivered by *BB* produces a cross field along the line of the pole pieces, which tends to wipe out the weak field due to the winding *ff*. It is evident that this will prevent the current from increasing beyond a certain limit, for beyond this limit the field due to *ff* will be entirely wiped out, and this would cause the machine to lose its e.m.f. Thus beyond a certain speed the machine should deliver a practically constant current. By adjusting a rheostat included in the field circuit *ff* any requred limit may be set to the current. The machine may be driven by belt from a pulley on the car axle, or, if the machine be large, the armature may be mounted directly on the axle itself. When run as a motor the machine behaves somewhat similar to a single-phase induction motor in that it possesses no torque when at rest, but when started in either direction will go on running in that direction. It exhibits the general characteristics of a series motor when running, the speed decreasing rapidly with an increase in load.

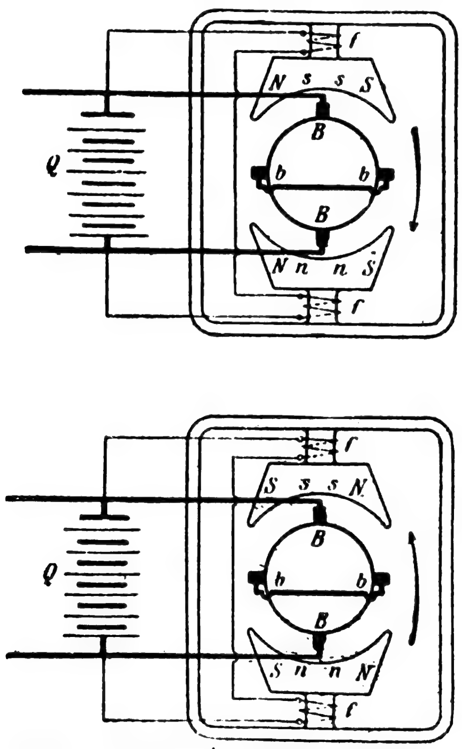

FIG. 1.—ROSENBERG'S INGENIUS DYNAMO.

Catgut Belting.—The durability and advantages of twisted catgut cord for driving purposes is referred to by Mr. Raffard in an article in *Revue de Mecanique*. The relative strength of catgut greatly exceeds that of the best leather, and it has been found in practice that gut cords will work effectively for long periods under a tension of 4,267 pounds per square inch, or ten times the load of leather belts. A round cord of catgut 0.39 in. in diameter would do the work of a leather strap 6 in. wide by one-fifth in. thick. In order that this material may operate under the best conditions, it should be manufactured as an endless belt, and not put together with hook or screw fastenings at the ends, as is usual in catgut lathe belts. Although such fastenings are very convenient in practice, they tend to greatly diminish the strength and durability of the belt; a joint made in the process of manufacturing the catgut cord is about 20 times as strong as the ordinary hook or screw eye fastening. As gut cords can only be obtained in small diameters, it is suggested that they should be used on grooved pulleys similar to those employed for rope drive.

Remarkable Engine Performance.—*The Engineer*, of London, contains the results of tests made on what it believes to be the most economical steam engine ever constructed. The consumption of steam per indicated horse-power per hour during one run was only 8.585 pounds. The engine is an inverted vertical compound of the marine type, with unjacketed cylinders nominally 21 in. and 36 in. in diameter by 3 ft. stroke, and was built by Cole, Marchent & Morley. Each cylinder had four piston valves, the admission valves being opened by eccentrics and closed by springs through a Dobson trip gear; the cut-off on the high-pressure cylinder being controlled by the governor and on the low-pressure cylinder by hand. The exhaust valves were opened and closed by eccentrics. Steam was supplied by a Lancashire boiler, and superheated in an independently fired Schmidt superheater containing 1,033 square feet of surface exposed to the gases and 11½ square feet of grate fire. The exhaust from the high-pressure cylinder was dried and superheated in the reheater before entering the low-pressure cylinder. The exhaust was discharged into a specially erected surface condenser in order that the steam consumption might be ascertained by measurement of the air pump discharge. This condenser had about 1,200 square feet of surface. In all, six trials were made—two at maximum load, two at about three-quarters load, one at rather more than half load and one at the lightest load possible, viz., driving the mill shafting only. During the tests the temperature of the steam at the stop valve of the engine was about 720° to 750° Fahr. and the steam consumption per indicated horse-power per hour was as follows:

471 indicated horse-power	9.187 lbs.
341 indicated horse-power	8.784 lbs.
258 indicated horse-power	8.742 lbs.
145 indicated horse-power	8.585 lbs.

The thermal efficiency of the engine, calculated on the basis of the method proposed by the Institution of Civil Engineers, gives about 22.07 per cent. The engine was said to have been working nearly a year before the tests were made. During the trials it ran most satisfactorily, without a leak anywhere and with every bearing cold. After stopping one of the high-pressure steam valves was taken out, and both the packing rings and the liner in which it worked were found in perfect condition. An incident which speaks well for the construction and workmanship on the engine occurred the day before the tests were made. The pyrometer on the superheater stuck at about 650° Fahr., and the fireman, thinking that the heat was not high enough, fired hard until the first indication of something wrong was that the covering of the pipes took fire. A thermometer was then placed in the engine stop valve pocket and indicated 840° Fahr. When it is realized that this means black red it will be granted that the engine will work satisfactorily with an abnormally high superheat.

New Lock Nut Washer.—There have been numerous devices and special designs of nuts and washers, or a combination of both, to make trustworthy lock-nuts. The latest that has come to our notice appears in *The Engineer*, of London. The feature consists of a washer which has a V-shaped projection diagonally across it. This collar fits into a recess in the bottom of the nut, the recess being made exactly to fit the collar. By this means when the nut is being tightened the washer is also turning with it. It is claimed that it is so difficult to loosen the nut, since it cannot move unless the washer moves, that it will always remain tight. The bear-

FIG. 2.—LOCK NUT WASHER.

ing surface of the washer being greater than that of the nut, the friction, and consequently the resistance to motion, is greater than if the nut were simply bedded on the washer without the projection.

The Leitner-Lucas Train Lighting Dynamo.—The London *Electrician* contains an illustrative description of the Leitner-Lucas system of train lighting which is in use on many European and Asiatic railroads. The dynamo is usually designed to generate a practically constant voltage over a wide range of speed. As will be evident from the diagram of connections shown in Fig. 4 the voltage regulation is electric and purely automatic, the mechanical device shown to the left being a reverse current cut-out. The illustration

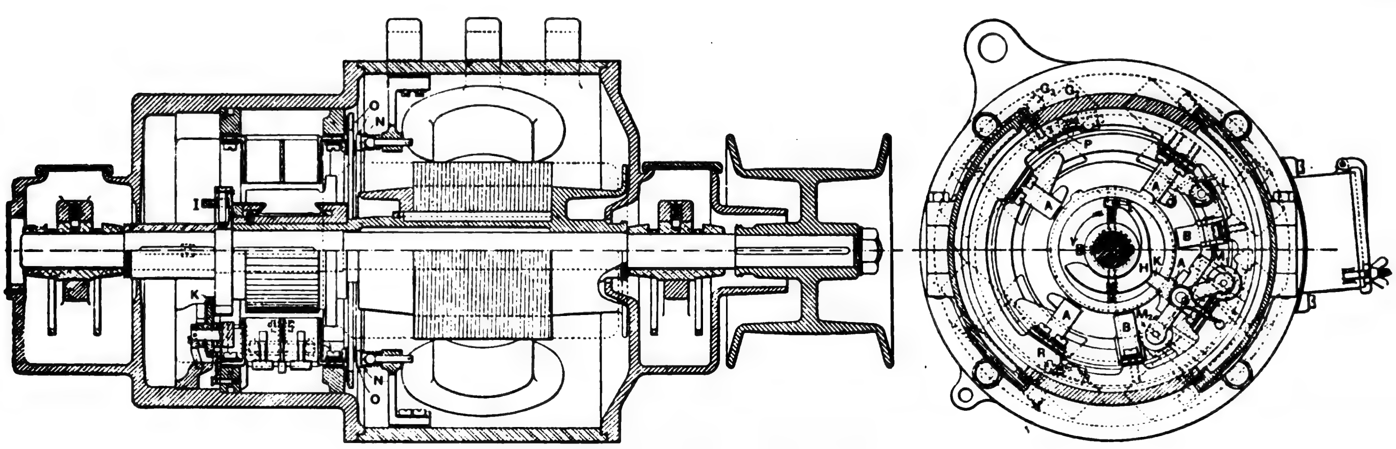

FIG. 3.—LEITNER-LUCAS GENERATOR.

represents the improved form, differing from the system formerly used in that one dynamo armature now performs the work previously done by two. In the old system, a small generator called the demagnetizing dynamo was keyed to the shaft of the main dynamo and served for weakening the field as the speed increased, thus causing the voltage at the dynamo terminals to remain practically constant. In the improved arrangement, however, this auxiliary machine is dispensed with, its place being taken by an extra pair of brushes, D D_1, bearing on the commutator. At starting terminal D_1 is positive and D is negative, so that the voltage between D and D_1 assists that at

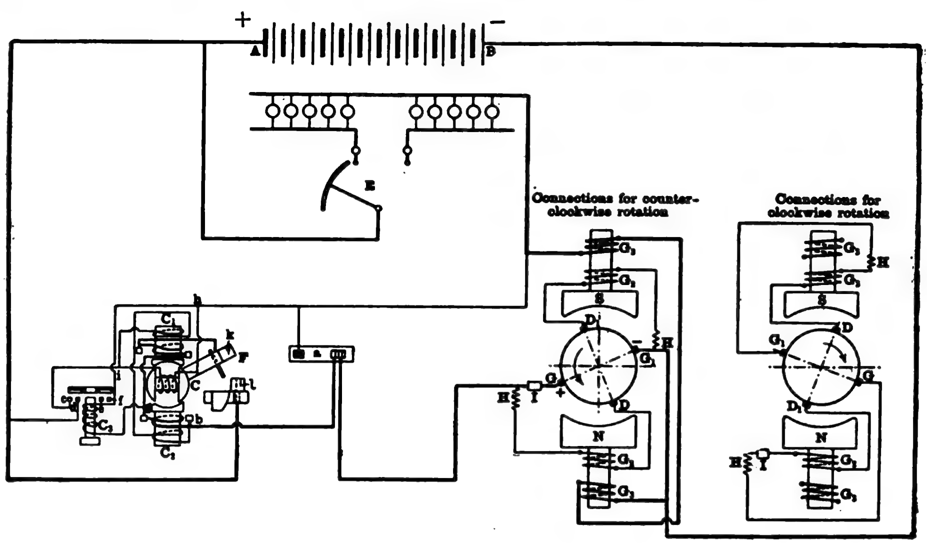

FIG. 4.—LEITNER-LUCAS TRAIN LIGHTING SYSTEM.

the main brushes in sending the exciting current through the field coils. The fields are thus rapidly built up; but as the current flowing out of the armature, G G_1, increases, the armature flux in the direction of G G_1 also increases and the original voltage between D and D_1 is gradually reduced and then reversed in direction, D_1 becoming negative and D positive. As the dynamo speeds up the voltage between D and D_1 rises and chokes the shunt current through G_2 more and more; the result being that the dynamo voltage is kept at a constant value. G_3 in Figs. 3 and 4 is a small field coil in series with the lamps and carries current as soon as the lamp circuit is closed by the switch E. While this auxiliary coil is not absolutely necessary, its use is advantageous as it renders the excitation of the dynamo quite positive and independent of the remanent magnetism. G_2 is an ordinary shunt winding across the main brushes, G G_1, and is protected at either end by a fuse, H. As actually constructed the generator has 4 or 6 poles, two of which are for the excitation. The automatic switch, C, performs the function of cutting the dynamo from the battery circuit whenever the back e.m.f. of the latter exceeds the voltage of the former. When the dynamo voltage has reached a value sufficient to charge the battery, the battery is again automatically cut in. Fig. 3 shows the details of the generator. The frame is of cast steel with cast iron end covers and laminated pole shoes. Its complete weight is about 3 cwt. and its normal output is from 40 to 50 amperes for a 12-cell battery (i. e., 24 to 32 volts). The four main brushes are marked A, the auxiliary brushes being denoted by the letter B. L is a small wheel with a toothed periphery fixed to a spiral spring and when turned one way or the other increases or diminishes the pressure on the carbon brushes. The action of the reversing mechanism is as follows: A suitably shaped metal piece, H, carrying the pin, I, rotates with the shaft. At normal speeds the heavy part of H is forced outward by the centrifugal force against the springs, and the pin, I, passes underneath the trigger, K, of the reversing mechanism. When the train is moving slowly the pin, I, strikes K, but the latter gives way and a faint tick is heard every revolution. When the train comes to a standstill, the pin, I, is farthest from the shaft, and when the train begins to move in reverse direction the trigger, K, is struck from the opposite side, and since it cannot

give way in this case the whole brush is caused to rotate. M_1 is a small trolley wheel which runs on a segment, and the backward rotation of the brush gear occurs only so long as M_1 runs on this segment. If the trolley wheel M_1 runs beyond this segment the trigger, *K*, gives way again to the pin, *I*, and the clicking sound is heard until pin, *I*, is drawn down on the shaft by the centrifugal force acting on *H*. The spring stops, *P*, *R*, prevent the brush gear from overshooting the mark. Instead of using flexible conductors in connection with the movable brush gear, suitable collectors, *N*, bearing on metal segments, *O*, are used. When supplying about 40 amperes at 26 volts no sparking is discernible at the dynamo brushes for speeds varying from 400 to 1500 r.p.m. A single battery with special Planté positive plates is used.

Telephone Protector.—*L'Industrie Electrique* contains an illustrated description of the protective device for telephone apparatus which has been devised by M. Van Deth, and possesses some advantages over the ordinary heating coil. The device is shown by Fig. 5 herewith and consists of a small solenoid, connected in series with the line. If an excess of current passes along the line the plunger of the solenoid lifts and in so doing strikes a detent and thus releases the spring of a contact which opens the circuit. The plunger of the solenoid then resumes its original position and the device may be reset by pressing on a projecting knob. The advantages claimed for this device over the

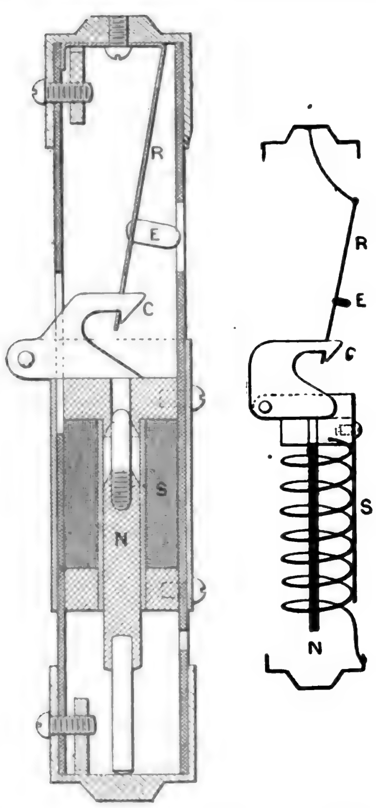

FIG. 5.—VAN DETH TELEPHONE PROTECTOR.

heating coil are the smaller resistance, the quick opening of the circuit, the easy resetting of the device and the inductance of the coil which assists the lightning arrester in its operation.

Street Lighting.—Our English contemporaries contain E. E. Hoadley's paper on street lighting read before the Incorporated Municipal Electric Association. The major portion of the paper is devoted to the lighting of side streets, where arc lamps are out of the question. In this respect the Nernst lamp has been found an efficient substitute. He gives his experience with this type of lamp at Maidstone. The author has some 350 posts at the present time, most of them having a ½-ampere lamp rigidly fixed and suspended from a swan-neck at the top of the existing gas column, the burner being about 11 ft. from the ground, each lamp being housed in by the upper part of a special reflector which is used to get a better distribution of the light. Clear glass globes are used, the general public preferring brilliancy to good distribution, although a good many prism globes were used at first. There are also some 30 posts fitted with the new type lamp, but these have been in use for so short a time that the author cannot speak with any certainty as to their performance. The former type, however, has been in use at Maidstone for about three years, and during this time the life of each individual burner has been kept very accurately, and from the results obtained from a good many hundreds, it is found that the average life is 676 hours, and this has somewhat improved lately. Very few resistances fail, but there has been at various times a good deal of trouble with the cut-out coils in the lamps burning out; this was pointed out to the German makers, and evidently more attention has been given to this point, as lately very little trouble in this direction has been experienced. It is the author's general experience that wet weather exercises a deleterious effect on the burners, which have to be replaced much oftener during a spell of wet weather than during an equal period of fine weather. The average illumination results obtained from a ½-ampere "A" type burner with a well-designed reflector compare very favorably with results taken by the author from a single gas mantle in good average condition throughout the town. Experiments were also made with the "Luna" type of lamp, but owing to the position of the burner the distribution of light is not in the author's opinion at all satisfactory or suitable for street lighting; no arrangement of reflectors that he has, up to the present, been able to devise has got over the fact that the larger proportion of the light is thrown vertically downwards. To sum up the author's experience with Nernst lamps in a few words, the greatest fault he has to find with them is their want of uniformity. This is most apparent in the life of the burners, as, although the average life obtained in Maidstone is 676 hours, yet they have had many burners in use for over 1000 hours, and several between 2000 and 3000, equally they have had many which have failed before they have reached 100 hours burning. This want of uniformity is also noticeable in the way in which the candle-power falls off, some burners do not appreciably drop for quite a long life, while others lose a great deal of their light-giving properties in a very short time, and will then last in this condition for a long while. The author then considers the three problems which confront the station engineer before he can get the street lighting into his own hands. To give a light at least equal to that given by the ordinary gas mantle: A ½-ampere "A" type lamp at 230 volts will give a degree of illumination superior to that given by a gas mantle, both when measured by an illumination photometer in the streets, and, what is far more important, when judged by the eye of the general public. This point having been settled, there remain the two more important ones, namely, that the cost shall not be greatly in excess of the cost of gas lighting, and that the electricity supply works shall get a profit out of the business. As a result of a great many inquiries the author finds that the annual cost per post for a gas lamp having a single mantle varies from $15 to $20 as a general rule, which price is inclusive of trimming and maintenance charges; and he thinks $17.50 an average figure. These gas lamps are generally placed at distances apart varying from 40 yds. to 50 yds., thus the cost of lighting a mile of street will vary from $612.50 to $770 accordingly. An equally illuminated street can be got by means of ½-ampere Nernst lamps placed at a distance of 55 yds., although in Maidstone, as the existing gas columns are used, they average 50 yds., and the author hopes to be able to show that a ½-ampere lamp can be kept alight from dusk till dawn for $17.50 per annum. The lamp having a 220-volt burner and a 20-volt resistance on a 230-volt circuit requires 390 Board of Trade units during the year, and has actually cost $2.25 for renewals of burners, resistances, etc., $2.50 for lighting and extinguishing and cleaning; interest and sinking fund charges, calculated at 6 per cent on $30, absorb $1.80, repairs and maintenance of fuses, etc., have actually cost 70c. per annum, thus leaving $10.25 for the 390 units of electricity consumed.

Current Limiter—*L'Electricien* contains an illustrated description of overload relay, the purpose of which is to control the action of a fuse. The device, which is shown diagrammatically by Fig. 6 herewith, consists of a wire through which the current to be controlled passes, and the expansion of which when heated allows it to be drawn to

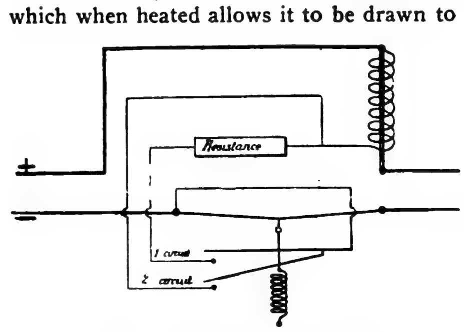

FIG. 6.—CURRENT LIMITER.

one side by a spring. When moved to the side the wire closes two contacts, one after the other. As shown in the diagram, a heating coil is placed around the fuse which carries the whole current in the usual way,

but is capable of withstanding a considerable overload. When a slight overload is thrown upon the system the wire expands and a contact is closed which results in current being sent through the heating coil connected in series with the resistance. By this arrangement the fuse will be melted in about five minutes should the load exceed the normal by a few per cent. With an excessive overload the expansion of the hot wire is so great that the second contact is closed. This cuts out the resistance of the heating circuit and melts the fuse in thirty or forty seconds. When this result obtains the circuit is of course opened and the wire in cooling cuts out the heating circuit. The device may be used on either alternating or direct-current circuits.

Statter Time-Limit Device.— The London *Electrician* describes the novel, yet simple, time-limit device shown by Fig. 7 herewith. It consists of a cylindrical plunger which is drawn up vertically into a solenoid when the current in the latter exceeds a predetermined amount. In order, however, to prevent the plunger from responding at once to the pull, a flat brass

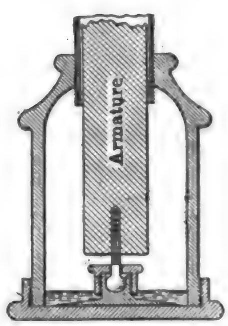

FIG. 7.—TIME LIMIT DEVICE.

disc is fixed at its lower end, the disc lying flat against the bottom of the receptacle which encloses the whole mechanism. The bottom of the receptacle is covered with a layer of oil or glycerine, and the plunger cannot rise immediately when an overload occurs owing to the "suction" effect. It rises ultimately, and the time it takes to overcome the suction effect depends on the pull. The receptacle referred to can be screwed up or down, so that the relative position of the plunger and solenoid may be speedily altered. This, of course, serves to adjust the current strength at which the device will begin to act.

Load Factor..—The London *Electrician* gives an abstract of a paper read at the tenth annual convention of the Incorporated Municipal Electrical Association by A. Sinclair, on the load-factor and its effect upon a central station. The author thinks it plain from his remarks that it is essential to the cheap generation of electricity to increase the load-factor of a station by every possible means. He would advise first, the increasing of the ordinary lighting load by systematic canvassing, thereby bringing before the notice of probable consumers, in an attractive form, by booklet or otherwise, the great advantages of electric lighting over other forms of illumination; lighting is mentioned because, although an increased lighting load does not materially decrease the cost per unit, still the larger the output the better it is for the general welfare of the undertaking. Secondly, public lighting should be extensively used, for by its use the financial position is so improved as to allow energy to be sold at cheaper prices; Edinburgh and Glasgow may be cited as typical examples of the fruitfulness of this supply. He also is of opinion that this point does not always receive its due consideration, and where it is tried, more or less extensively, its progress is often throttled by the charge per unit being too high, thus affording adverse comparison with other forms of street illumination. Thirdly, and on this point he lays particular stress, that great hopes may be held for the future of stations by dispensing power on a large scale to small users at cheap rates. Where powers are held for the hiring out of motors, this class of consumer is making great headway because many view with much apprehension the scrapping of their present plant and substituting electricity with what they think the possibility of failure. When they know that by hiring a motor their liability—should they wish it—ends with the year, they are more prone to enter into a trial in what they consider to be more or less an experiment. The experience in this direction in Swansea has been to add very largely to the business, and to some extent to account for its successful running; in two years they have improved their load-factor from 12 to nearly 18 per cent. With regard to traction he says not many stations are fortunate to have this valuable asset, but the experience of those having such a load is quite sufficient to demonstrate its help in producing excellent results. Another feature touched upon was his belief that electricity cannot be purveyed; a uniform price per unit cannot be fixed, but must depend on the nature of the supply—*i. e.*, quantity and load-factor. The maximum demand system meets the requirements of the case, but, unfortunately, its explanation is so complicated to the ordinary individual that he either cannot or will not try to understand it. The author suggests that if a system simple in itself could be arrived at whereby a customer's load-factor could be readily and easily ascertained, his charge per unit could then be regulated by a discount on its price. By some such means the ordinary customer, usually a man of business, would be appealed to because he would readily accept the situation if he is aware that his account is subject to a discount on the quantity of energy he uses, whereas when confronted with the complex explanations of the maximum demand, he is amazed —always confused—and if his bill be high, never satisfied.

Some Recent Electrical Patents

Multiple-Switch Motor Starter.—Motor starters comprising a series of switches arranged to be thrown in successively and thereby cut out sections of a starting resistance are familiar to every one concerned. One of the later developments along this line is represented diagrammatically by Fig. 1 and has been patented by Mr. Frederick Mackintosh, of Schenectady, N. Y. The apparatus includes an overload circuit-breaker, 4, of the usual type, a no-voltage circuit-breaker, 11, and the multiple-switch starter. When the no-voltage switch is closed it sets a multiple latch in the paths of detents on the starting switch levers, 18, this latch serving to hold the switches in after they have been closed by hand and to release them all when the no-voltage

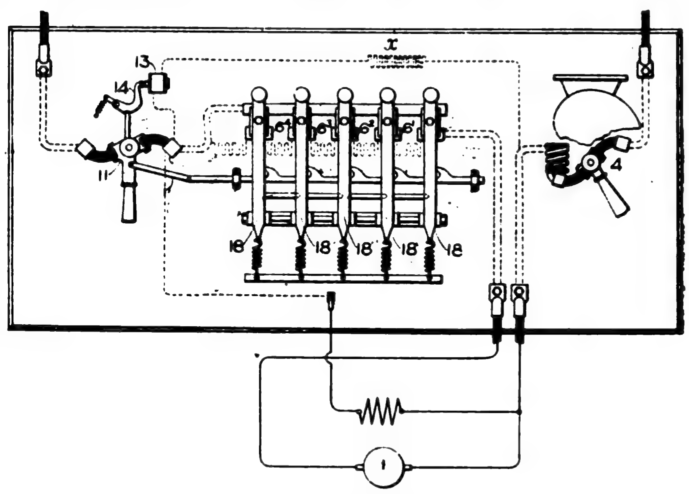

FIG. 1.—MULTIPLE SWITCH MOTOR STARTER.

switch opens. The no-voltage switch is held closed by the dog, 14, which is in turn held by the release magnet, 13, connected across the motor terminals in series with a resistance, *x*. If the current supply should fail or if the overload circuit-breaker, 4, should open, the release magnet will, of course, be de-energized and allow the spring to pull away the dog, 14, releasing the switch, 11; this switch will be opened by a spring (not shown) and release the individual starting switches, 18. The connections of these are of the familiar plan. Patent No. 793,454.

Carbon Resistance Rods.—It is desirable in the application of "stationary" lightning arresters to provide a high resistance in series with the discharge gap in order to limit the flow of generator current after the arc has been established by the lightning discharge. In practice difficulty has been found in obtaining a suitable material of which to make this resistance. According to a patent recently issued to Mr. Willis R. Whitney, of Boston, Mass., he proposes to use a mixture of carbon dust and some binding material, such as ordinary clay,

and to employ novel means for making rods of this mixture which shall have uniform resistance. The inventor states that the lack of uniformity hitherto obtained was due to a surface coating of carbon, and that when this is removed, even to a depth of only a few thousandths of an inch, the conductivity of the rod is greatly decreased, and rods of the same size and shape have almost uniform resistances. The removal of the surface coating, he states, is conveniently effected by exposing the rods to intense heat in the presence of air. Patent No. 792,638.

Motor Controller.—In the construction of speed-controlling rheostats for electric motors it is customary to equip the apparatus with a spring to return the regulating arm to the "off" position when the latter is released, and a detent of some sort adapted to hold the arm in any position at which it may be set, the detent being usually released electromagnetically. A combined speed-regulating rheostat and motor starter of this general type has been devised and patented by Mr. W. C. Yates, of Schenectady, N. Y., the essential features of which are shown by Fig. 2. The detent for the controlling arm consists of a brake band, 13, around a drum, 12, the drum being mounted on the same spindle with the arm and the band being controlled by an electromagnet, 19. The device further embodies the feature of separate starting and regulating contacts, the brake remaining entirely relaxed while the arm is passing over the starting contacts, 4. This is effected by the method of connecting up the brake magnet; so long as the arm is within the range of the contact strip, 7, the field winding, 25, of the motor is connected directly across the circuit, but when the arm passes to the button, 8, the brake magnet is inserted in series with the field winding. The starting resistance, 5, is in the armature circuit, as usual, while the speed-regulating resistance, 9, is in the field circuit. When the starting resistance has been all cut out the magnet and brake come into action and hold the arm in any position beyond; upon the failure of the supply current the magnet releases the brake, of course, and the arm is drawn to the "off" position by a spring in the ordinary manner. Patent No. 793,494.

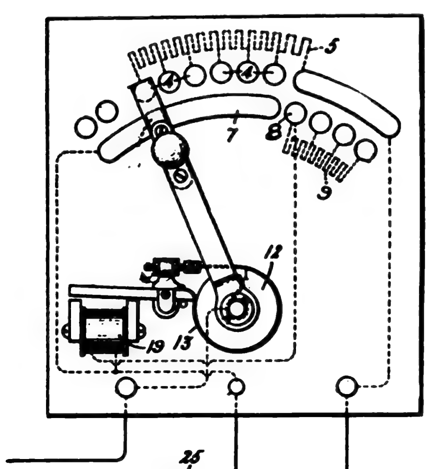

FIG. 2.—MOTOR CONTROLLER.

CENTRAL STATION ENGINEERS.

X.

G. W. Brine.

G. W. Brine was born in Cambridge, Mass., on Sept. 9, 1867. He graduated from the Winchester High School in 1884 and made his entree into the electric light field as assistant bookkeeper in the office of the southern district of the Edison General Electric Company, the headquarters of which were located in Atlanta, Ga. He retained this position until the district was abolished, shortly before the consolidation of the Edison General Electric Company and the Thomson-Houston Electric Company, when he accepted a position in the New York office of the General Electric Company, afterward being transferred to the Boston office. He returned to Atlanta. Ga., in August, 1892, accepting the position of auditor of the southern office of the General Electric Company. He remained with this company until 1894, and on January 15 of that year he accepted a position as cashier of the Georgia Electric Light Company. His steady application to the interests of the company resulted in his being promoted to secretary-treasurer and manager, which position he held until the consolidation of all the railway and lighting companies in the city of Atlanta, in April, 1902. He was then made vice-president and treasurer and manager of the electric department of the Georgia Railway & Electric Company, into which company all the other companies were merged.

G. W. BRINE.

THE LIGHTING SITUATION IN SPRINGFIELD, OHIO.

To the Editor, American Electrician:

We noticed a statement in your June number, in the department of Central Station News, concerning the situation in the electric light business in Springfield, Ohio. This item stated that the People's Light, Heat & Power Company had bought up all of the electric light plants and merged them into one, thereby giving them a monopoly of the business in this city. We wish to correct this statement, as The Home Lighting, Power & Heating Co. has been established in this city for five years and furnishes at the present time 75 per cent of the commercial lighting of the city. It is now putting in a complete steam heating system for heating the public and private buildings of Springfield, and has just purchased 1000 horse-power more in boilers and a 500-kw., three-phase Westinghouse turbine-generator, which in addition to our 110-volt machines, gives us 1000 kilowatts of generators, besides a 300-kw. motor-generator.

As we are in the business to stay in this city, and are furnishing a great amount of the private lighting, we think your statement does us an injustice; The People's Light, Heat & Power Co. certainly has not a monopoly of the business here. A correction in the August issue would be no more than justice to ourselves, and we would appreciate it.

Springfield, Ohio. W. N. ZURFLUH.

[We take much pleasure in giving space to the above correction of the statement to which Mr. Zurfluh refers. It was made in good faith, of course, on what we considered good authority, but it is manifestly impossible for us to verify news items of this character before publication. We use all known precautions against misstatements, but it is impracticable to prevent them absolutely, and when they occur we appreciate corrections of them.—EDITOR.]

NOTES.

New Incandescent Lamp.—A Frenchman named Canello has devised a new incandescent lamp having a filament formed of oxides of alkaline earths covered with a thin layer of metallic osmium.

The Colorado Electric Light, Power and Railway Association announces that its third annual convention will be held at Glenwood Springs, Colo., September 18 to 20 inclusive.

Machinery Wanted.—It is authentically reported that the Standard Electric Light, Heat & Power Company, of Avoca, Pa., is in the market for a direct-connected generating unit and a belted set, the generators to give two-phase alternating currents at 60 cycles.

Condolence in Order.—The city council of Ashland, Ore., recently passed an ordinance to install a municipal electric light and power plant to cost about $50,000.

United Engineering Building.—The committee in charge of the work on the United Engineering Building has awarded the contract for the erection of the structure; the contract price was $795,000 for the edifice alone. It is hoped that the building will be completed and furnished ready for occupancy by October, 1906.

Electricity and Red Noses.—A cable dispatch from Berlin says: "Prof. Lassar, a famous Berlin skin specialist, has found means to restore red noses to their normal color and uses. An instrument, shaped like a large tooth brush, with forty platinum wires instead of bristles, is used, and this is connected with an electrical machine. The treatment consists of hammering the lurid nose till it bleeds, when the treatment is stopped for a day. Two hammerings a week for some months suffice to eliminate the excessive redness." It is not stated how much hammering is required to eliminate the nose entirely.

"Successful" Municipal Plant Operation.—A daily New England paper has someone on its staff who is not devoid of technical intelligence. In a recent issue it was stated that "Marblehead appears to have been the most successful of the towns operating their own (lighting) plants, for its net loss amounts to only $1500, while that of Danvers amounts to $4000, and Peabody's is $9000." If the writer had gone farther afield he might have congratulated Marblehead more enthusiastically, if not violently, upon finding that at Greenfield, Ind., where the city owns and operates the electric light plant and water works, more than $17,000 is required for making repairs and improvements on the light plant, while the city not only has no money available, but is in debt up to the legal limit.

Street Railway Conventions.—The annual convention of the Street Railway Accountants' Association of America will be held in Philadelphia, Pa., September 28, 29 and 30, with headquarters at the Hotel Walton. The Mechanical and Claim Agents' Association will meet on Monday and Tuesday, September 25 and 26. The American Street Railway Association will meet on Wednesday and Thursday, September 27 and 28. The annual convention of the American Street Railway Association will be held in Philadelphia, Pa., September 25 and 30. A pavilion of the Philadelphia Museum and an adjoining building will be used for exhibition purposes. The Pennsylvania Railroad has a switch track entering the building, which has about 500 feet of track under cover. Outside of the buildings there is space for outdoor exhibits and two railroad tracks.

Electrical Contractors' Convention.—The National Association of Electrical Contractors held its annual convention in Boston the week beginning Wednesday, July 19. The convention was accompanied by a large exhibition in Mechanics Building, where also the sessions were held. As the proceedings are conducted with closed doors and the convention is in session at this writing there is nothing of interest to report as to what was done. The intense heat has interfered with a very large attendance, but there were 173 delegates registered and 263 guests—supply men, exhibitors, etc. The New York contingent arrived on a special train under the conduct of Mr. Alex. Henderson, master of transportation, some thirty being on board and a very pleasant trip being made. The dinner of the association was given on Wednesday night, but the attendance was limited to members of the association only. On Thursday the association and registered guests went on a trip to Nantasket Beach by boat and dined at Wade's Nantasket Point Hotel.

Ontario Power Company Begins Operations—On July 1 the Ontario Power Co., of Niagara Falls, for the first time applied potential to its 60,000-volt transmission line. Work was begun upon this development of 200,000 electrical horse-power in March, 1902, over three years ago. On June 15 water was admitted to the intake works, now completed for the full capacity, and on June 22 the first 10,000-h.p. unit, generating three-phase, 25-cycle current at 12,000 volts, was put in motion. The first set of step-up transformers to raise the potential from 12,000 to 60,000 volts, each of 2500 kilowatts capacity, oil-insulated and water-cooled, was put in service on July 1. The permanent transmission line, at present only partially completed, consists of duplicate lines of 49-ft. tripartite steel towers, carrying porcelain insulators of a new type on iron pins, and aluminum cables nearly an inch in diameter. The average length of span is 550 feet. The present expectation is to have three units, with a total capacity of 30,000 horse-power, delivering power by the last of September.

Wages for Beginners.—The General Electric Company, which is looking for apprentices at its West Lynn factory, in response to inquiry, announces the following salaries: To graduates of high schools only—drawing office apprenticeship course, $5.33 per week for first six months, $6.30 per week for second six months, $7.28 per week for third six months, $8.25 per week for fourth six months, $9.22 per week for fifth six months, $10.67 per week for sixth six months. There will also be a bonus of $75 distributed if the three years of service have been satisfactory. Shop apprenticeship course, $4.48 per week for first six months, $5.60 per week for second six months, $5.72 per week for second year, $7.84 per week for third year, $9.24 per week for fourth year; bonus of $100 at expiration of term if services have been satisfactory. For high school students and grammar school graduates—shop apprenticeship course—$3.36 per week for first six months, $4.48 per week for second six months, $5.60 per week for second year, $7.00 per week for third year, $8.40 per week for fourth year; bonus of $100 at expiration of term if services are satisfactory.

Testing Rubber-Insulated Wire.—A conference was recently held at the rooms of the National Board of Fire Underwriters for the purpose of devising ways and means for testing all rubber-insulated wire manufactured under the rules of the National Board of Fire Underwriters and to prevent the introduction into commercial use of any wire which proves inferior to the standard demanded by the National Board. Reliable manufacturers would then be protected against unfair competition and the use of wire with defective rubber insulation would be practically prevented. A committee consisting of six members to form the Wire Inspection Bureau was chosen at this meeting. This bureau will draw specifications for testing rubber-insulated wire manufactured under the rules of the National Board, decide on such tests and when and how they are to be made. The bureau will also appoint the necessary electrical inspectors, three being considered sufficient at present, who shall from time to time visit the testing laboratories of any factories making rubber-insulated wire and supervise, make and verify tests specified by the bureau. The necessary expenses will be raised by issuing stamps and selling these to the different manufacturers at a charge of one cent per 100 ft. of wire tested. These stamps will be attached to the coils of tested wire by the manufacturers themselves and serve as a guarantee that wire so stamped has successfully withstood the tests specified by the bureau. The majority of the rubber-covered wire manufacturers have agreed that on and after October 1, 1905, all National Code wire manufactured by them will be made up under the new specifications and duly tested, and will also bear the identification mark of the Wire Inspection Bureau. It is understood that a reasonable time will be allowed after this date for the disposal of code wire, manufactured before October 1, not bearing the stamp, and with this understanding the October list of electrical fittings will contain the names of all rubber-covered wire manufacturers agreeing to the tests and to the use of identification stamps. The Wire Inspection Bureau will supply identification stamps for 250-ft., 500-ft. and 1000-ft. coils. No wire will be considered as having been tested which does not have an identification stamp. The stamp will be on linen paper and will be fastened to the shipping tag attached to wire coils. They will be provided with serial numbers and on coils of less than the above specified lengths a credit for excess in stamp value may be obtained from the Inspection Bureau. The stamps are to be cancelled by the manufacturer when used, the date of manufacture of wire also being plainly shown. The Wire Inspection Bureau specification giving factory tests, which will be required on all wire having approved stamps, will be issued shortly.

AMERICAN ELECTRICIAN

WITH WHICH IS INCORPORATED

Electrical Industries.

CECIL P. POOLE, Editor.

Issued on the first of each month by the

McGraw Publishing Company

114 Liberty Street, New York.

Address all business communications to AMERICAN ELECTRICIAN, *114 Liberty Street, New York. Matter intended for publication in the reading columns should be addressed to the editor.*

Subscription price, $1 per year, postage prepaid, in the United States, Canada, Mexico and Cuba; $2 in all foreign countries. The date on wrapper shows when subscription expires. Subscribers should give their old as well as their new address when requesting a change in address. This should be received a week in advance of the desired change. No copies are kept on sale beyond fifteen months from date of issue, except in bound volumes.

Advertising rates sent on application. Advertisements received for insertion up to the 25th of the month prior to date of publication. Changes in standing advertisements should be received not later than the 15th of the month to insure their insertion in the next issue.

Remittances should be by check, New York draft, express or postal money order, payable to AMERICAN ELECTRICIAN.

Entered in the Post Office at New York as second class mail matter.

Vol. XVII. AUGUST, 1905 No. 8

The AMERICAN ELECTRICIAN *has the largest circulation of any electrical journal published. Of this issue,* 16,500 *copies are printed. The total number of copies printed so far this year is* 145,500, *or an average of* 18,187 *per issue.*

CONTENTS.

A Progressive Central Station Idea.

An interesting piece of central station advertising is now being carried out in Cambridge, Mass. The Cambridge Electric Light Company recently completed a new plant on Western Avenue, bordering the Charles River Parkway, and visitors are encouraged to visit and inspect the station, as in the case in many other places where interesting plants have been installed. When anyone applies at the company's office for a pass through the station, he is handed a neat pamphlet which is an illustrated guide to the plant and enables the visitor to go through with his eyes open to the purpose and meaning of the equipment. The pamphlet describes in very concise but clear phraseology all of the machinery and apparatus, from the coal-conveying cars to the lightning arresters, explaining the several conversions of energy along the way. The booklet is illustrated with excellent reproductions of photographs, and at the end is an inset showing the view from the top of the chimney, which is 255 ft. high. The Boston Edison Company has also distributed pamphlets descriptive of its system and stations, these being ordinarily found at the company's permanent Head Place exhibit. The idea is an excellent one.

Ventilation in Isolated Plants.

Although the engine and boiler rooms of most isolated plants installed in restricted locations necessarily inflict considerable discomfort on the operating shifts in hot weather, much can be done to relieve the situation by the judicious employment of fan motors. In fact it is difficult to suggest a better way in which the owner of such a plant can spend a little money for the comfort of his employees than to purchase a few small electric fans for use in the hot corners of the premises. For many reasons the tenants of modern office buildings have been growing more and more dependent upon the fan-motor to carry them through the rigors of the hot summer, so that it would be trite to argue the importance of such equipment as a necessity instead of a luxury; the fact is almost universally appreciated. The point is, however, that the use of the fan-motor in the engine and boiler room has not as yet been pushed to anything like the degree that it reasonably might be.

What is needed in practically every case is a complete change of air in continuous and steady progression; for which purpose there must be an appropriate inlet and outlet. Little is gained by simply stirring up the air over and over again by operating a single fan-motor in one corner of a practically shut-in room. The proper design of a modern isolated plant should naturally include the provision of adequate ventilating facilities, but where such work has not been done it is seldom a difficult matter to rig up at least a temporary series of ducts for use while the warmest weather lasts, and if the matter is intelligently handled the results ought to be thoroughly satisfactory. In the boiler room the main point is to bring cool fresh air from out of doors; the fires will generally dispose of the outlet problem, although an exhaust fan in the upper part of the room is sometimes a great help. Both inlet and outlet facilities need careful planning in the engine room, and throughout the entire plant an important point is not to neglect the condition of the pipe covering. The cost of operating even half a dozen fan-motors continuously is so small that it is worth trying in every case where the ventilation problem presses.

Power Plant Design.

Although one of the most interesting things about power plant design is the variety of treatment possible under different conditions, there is no doubt that such work is often carried too far away from the fundamental features of practice which nearly two decades of experience have shown to be desirable. It is not so much a question of special or standard apparatus as it is a matter of arrangement. In almost every power plant which we visit, notable differences in design are immediately apparent in comparison with previous installations, and while this is to a certain extent natural and desirable, it is frequently impossible to escape the conviction that the designers failed to appreciate the lessons of previous work.

For example, in two recent office building plants the power and lighting loads are distributed from the same and only set of bus-bars, and it is not too much to say that the result is a disgrace to modern engineering. Years ago it was shown that where the power load is heavy in proportion to the lighting output, incandescent lamps do not operate smoothly on the same circuit that supplies electric elevators; unless a storage battery is installed to take up the elevator current fluctuations, there is small hope of good regulation at the lamps. Every time the elevators start, the lights are certain to dim badly; in one "modern" plant the potential across the bus-bars was found to vary between 105 and 120 volts whenever

the motors drew current ranging from 50 to 500 amperes.

Quite apart from the question of lamp depreciation stands the more important matter of giving good service to the tenants. Attractive as the modern office building may be in comparison with the older business structures now, so rapidly being abandoned by progressive firms and houses, it cannot expect to hold its own in the close competition of these days unless its electrical and mechanical service is up to the best standards of the art. It is very poor policy to spend many thousands of dollars upon vestibule and corridor decorations and then supply the tenants with inferior elevator service, poor ventilation and unsteady illumination. It is far better to spend enough money on the power plant to provide separate machines for elevator and lighting service; or, if this cannot be done, to install a storage battery or get the manufacturers to advise what other correction is practicable. One way out of the trouble is to supply the lights from the local central station mains, leaving the motors to be supplied from the isolated plant bus-bars. All methods, however, are more or less expensive, and of the nature of makeshifts, except the fundamental plan of entirely separating the lighting and power circuits. If this is provided for in the original design, no trouble can occur, and the excellence of the service and operating economy are certain to justify an additional first cost of the installation.

Electricity in the Hospital.

Few persons whose attention has not been drawn to the matter realize the extent to which the modern hospital depends upon the electrical engineer for its comfort and convenience. As everywhere else, the cleanliness and flexibility of electrical equipment peculiarly adapt it to the exacting demands of organizations for the relief of physical ills. There is the question of ventilation, for instance. In the winter an even temperature is of great importance in hospital wards. An automatic system of electric heat regulation holds the thermometer within two or three degrees of standstill. In the summer the electric fan changes the air with high efficiency, and its noiseless operation is a great boon to the sufferers. From 3000 to 5000 cubic feet of fresh air per patient per hour are required in general hospital service, and the electric motor meets the situation with perfect success. Distributed ventilation is best secured through the flexibility of electrical equipment. Then there is the autopsy table, formerly associated with unpleasant odors. By placing a motor of about ½ horse-power beneath the table direct connected to a 24-in. exhaust fan delivering into a suitable duct, downward ventilation of the table is secured, with the most satisfactory results in the way of freedom from disagreeable air. In the same way the operating room offers excellent opportunity for the extraction of ether fumes and other contamination of the atmosphere.

The advantages enjoyed by the use of electric fans in hotel kitchens and laundries are available in the culinary and washing departments of the hospital. Electrically driven dish washers, extractors, mangles and ironing machines, and electrically heated flatirons, bosom, collar, cuff and neck ironers, all find a sphere of usefulness in hospital and sanatorium service. In the Agnes Memorial Sanatorium at Denver, but twenty minutes are required to dry work in the electrically ventilated laundry drying-room, in comparison with two hours by the older methods. For certain classes of work the electric heaters used in cooking are admirably adapted to hospital requirements. The localization and concentration of heat exactly where it is needed and without the annoyance of dust, dirt, smoke, ashes and cinders, are cardinal points of advantage. The electric heating pad of soft lamb's wool, with its even temperature, is immeasurably superior to the leaky, heavy and gradually cooling rubber hot-water bottle.

Almost every important hospital is now equipped with X-ray apparatus, medical induction coils, small incandescent lamps and mirrors for surgical work; cautery appliances, cataphoresis batteries, etc. In some cases small motors are used to operate tiny circular saws designed for bone cutting in delicate operations. To name all the appliances of surgery and medicine in which electricity plays a part would require the space of a catalogue. The list of electric lamps useful in hospital service covers many different types, ranging from the 8-c.p. or 16-c.p. lamp employed in ward and private room lighting to the smallest exploring lamp available for physical examinations. Some of the public waiting rooms and certain of the offices and corridors require even larger illuminating units, such as the Meridian or Nernst lamps, for the proper solution of the lighting problem. It would be difficult to cite any other case of lighting practice where the atmospheric purity of electric illumination is more important than it is in the hospital. Turning to the smaller applications, the electric annunciator, small buzzer and interior telephones have outlawed the crude and noisy speaking tube, and in the private fire alarm system we have but another evidence of the part which electricity plays in the splendid work of life and property saving.

Finally, the small motor has many other uses in the hospital besides the driving of ventilating fans. Many hospitals are equipped with small carpenter and machine shops, private laboratories, air compressors for cleaning, pumps, ice-making machinery, and refrigerating apparatus of great variety. Here the electric motor applies with the same and high degree of satisfaction that has attended its use in other classes of work. The cost of attendance may be cut down—and in few cases is the cost of labor proportionately higher than in a hospital. A hospital lighting and power load is well worth obtaining by the progressive central station man, and as time goes on the usefulness of electricity in this field will doubtless be more and more recognized.

Our "How-to-Make" Articles.

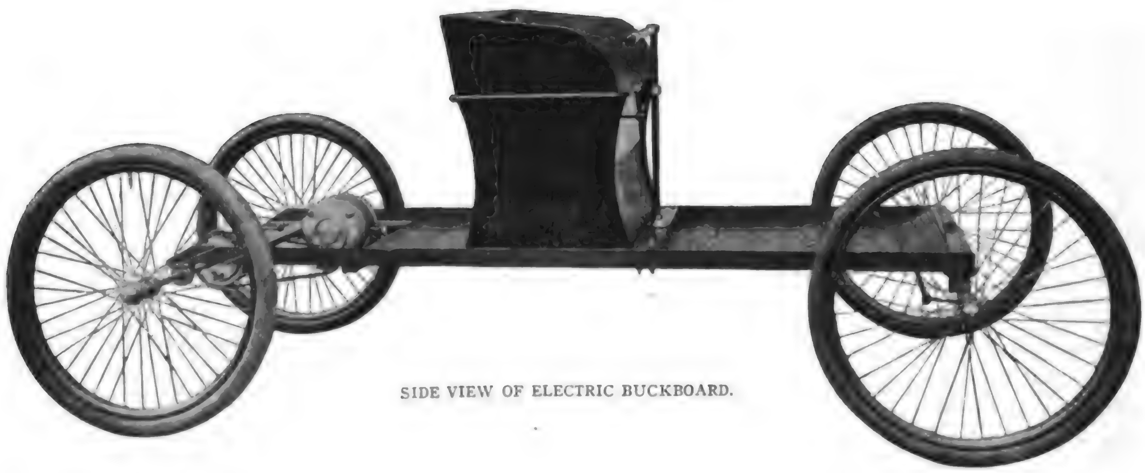
As all regular readers know, one of the chief features of this journal is the article which follows immediately after this page of each number of the paper. This article gives instructions for the design or construction (or both) of some piece of machinery or apparatus, and we receive a gratifying number of letters each month concerning the "how-to-make" article in a previous number. Many of these, however, ask for information as to where the apparatus can be bought outright, ready for service, and we take this opportunity to inform all readers that we do not publish detailed descriptions of apparatus that is already on the market. The object of the articles referred to is to enable readers to build the apparatus or machinery, not to buy it. Upon consideration it should be clear that the publication of instructions for making apparatus or instruments that have been regularly put on the market by manufacturing establishments could scarcely be considered fair to the manufacturers. In many cases, patterns and rough or partly finished parts of the machines or apparatus described in our articles may be obtained from some model-making establishment, and in a few cases, such establishments have taken up the manufacture of the apparatus after it has been described in our columns; but we never under any circumstances publish manufacturing descriptions of commercial instruments, machines or devices.

HOW TO MAKE AN ELECTRIC BUCKBOARD.

BY J. C. BROCKSMITH.

The Battery and Controller.

The builder may have his choice of any of several good makes of storage batteries which can be used in this machine. The battery compartment is of suitable size to contain 16 cells E 18 Edison battery; also an Exide battery of 16 P V 5 cells can be accommodated.



SIDE VIEW OF ELECTRIC BUCKBOARD.

In case the Edison battery is used, the motor would have to be wound for 20 volts, and in the case of the Exide battery the winding would be for 32 volts. Just what the winding will be for any voltage can be easily deduced from the figures already given by remembering that a reduction in the voltage of one-half would mean an increase in the cross-section of both field and armature wire to double the previous value, or an increase in the size of three gauge numbers. In this way any winding may be computed by simple proportion.

For the benefit of those who wish to construct their own battery, one used by the writer with good results will be described. The battery is of the lead type with pasted plates, the paste being applied to grids cast from an alloy of lead and antimony, containing 12 per cent of the latter metal.

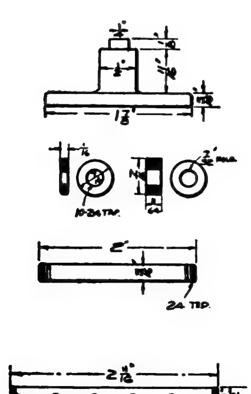


FIG. 22.—SECTION OF GRID AND DETAILS OF RODS, WASHERS, ETC.

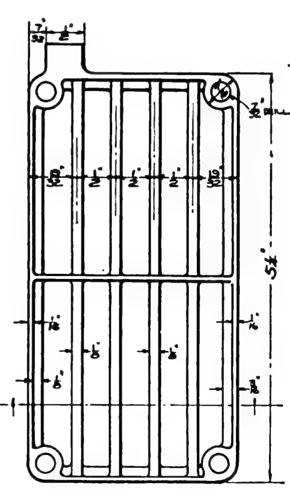

FIG. 21.—DETAILS OF GRID.

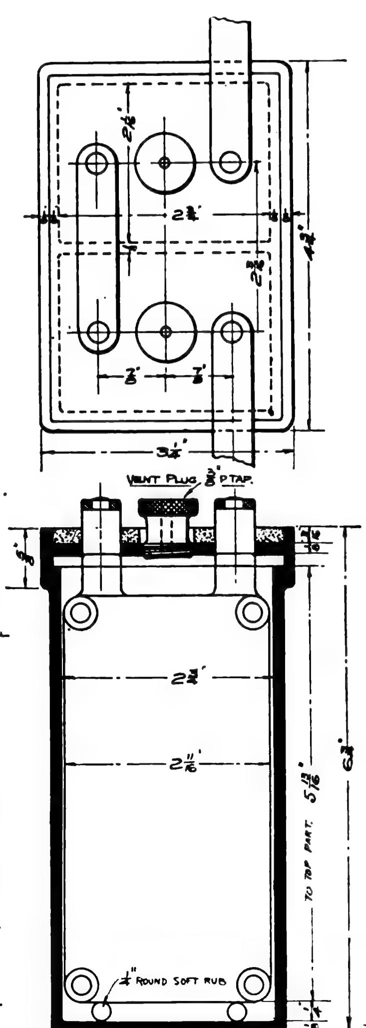

FIG. 20.—SECTION AND TOP VIEW OF COMPLETE DOUBLE CELL.

Fig. 20 illustrates the complete double-cell unit. A rubber jar is used which has a partition in the center; each compartment contains a five plate element consisting of 2 positives and 3 negatives, the end negatives being only one-half the thickness of the other plates. The weight of each element alone is 3¼ pounds, and the weight of the complete double cell with solution is 8½ pounds.

Fig. 21 is a detail of the grid used for both positives and negatives. It consists of a light rectangular frame having sides of T-shaped section and provided at the corners with bosses for the binding rods to pass through. The frame serves to give a definite form and thickness to the mass of active material, and the current is conducted to and from the mass by means of the vertical rods which are imbedded in the active material.

A lug is provided at the top of the grid for making connections with the finished plate.

The material which is applied to the positives consists of minium or red lead with a slight admixture of litharge. This is moistened with a solution of ammonium sulphate, and while in a plastic condition the grid is filled until the material stands a trifle above the edges of the frame. The grid and contents are then subjected to a strong pressure between some layers of blotting paper in a suitable press, which removes the excess moisture and compacts the material so that it now is flush with the edges of the frame.

The negative grids are treated much the same as the positives, except that in this case the material consists of litharge with a slight addition of red lead, and the whole is moistened with dilute sulphuric acid.

After the plates have been prepared in this manner and have been allowed to become dry and hard, they are assembled in the form of elements by means of the hard rubber rods and washers shown in detail in Fig. 22. It is not necessary to use pure hard rubber for this purpose; some of the cheaper compositions will answer just as well. The washers can be most conveniently cut from a tube of suitable diameter. In addition to the rods and washers some perforated and corrugated separators are slipped between the plates as additional precaution against short-circuits.

When the plates are properly assembled the plates of the same polarity are connected together by soldering on the pillar connecting pieces shown in detail in Fig. 22. These are cast of lead-antimony the same as the grids; in order to protect the terminals from being acted on by the electrolyte, they should be dipped in acid-proof paint after being soldered on.

The elements are now placed in their jars and connected in series and formed by passing a current in one direction through them, preferably continuously, until all the material on the positives has been converted into peroxide, by which time

the negatives will also have been reduced to spongy lead. The state of formation is best determined by the appearance and color of the plates, which should be a deep brown, almost black, when wet, for the positives and a dark slate color for the negatives; the color, of course, should be uniform all over the plate.

REAR VIEW OF ELECTRIC BUCKBOARD.

During the process of forming, the electrolyte used should be of much lower strength (about 1100 sp. gr.) than the regular used during working the cell, in order to avoid as far as possible sulphating the material, which would delay the formation. When fully formed the forming solution may be turned out, the plates washed, and replaced in the regular electrolyte of 1250 sp. gr., which must be mixed and allowed to cool before being placed in the jars.

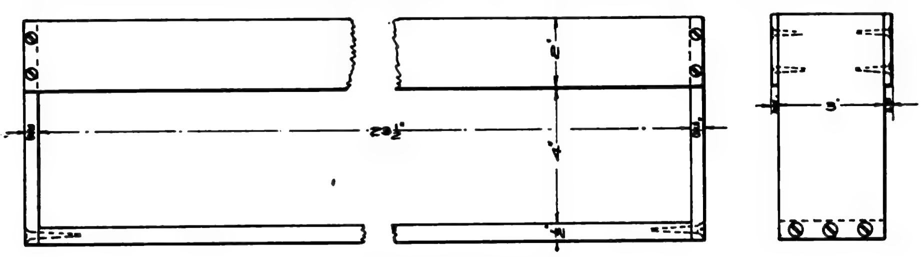

FIG. 23.—BATTERY TRAY.

Each cell may now be sealed by pouring in on top of the cover a layer of sealing compound, which is heated until quite fluid and will then adhere firmly to the sides of the jar, rendering it acid tight.

In order to combine the cells in convenient units for handling and connecting to the controller some wooden trays are necessary, which are shown in Fig. 23. Four such trays are used, each containing five double cells. The trays are best made of cherry and should be well painted with P. & B. or acid-proof paint.

In the operation of the vehicle the cells should not be discharged below 1.75 volts per cell or 70 volts for the entire battery in series. In charging a high rate can be used at first, if the cells were completely discharged; this should be gradually reduced, as the charge comes up, until the battery shows about 102 or 103 volts, with a current of 3 amperes flowing, when they may be considered fully charged.

The battery should be gone over occasionally and the condition of each individual cell determined to see that the electrolyte is of the proper strength and completely covers the plates, and that the voltage is right and there are no weak cells.

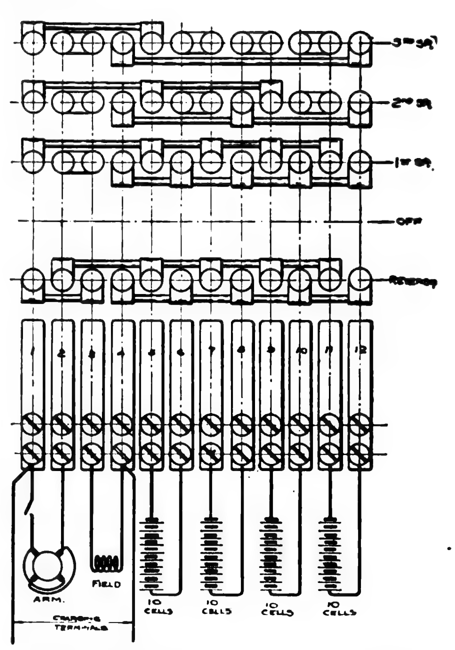

FIG. 25.—DIAGRAM OF CONTROLLER CONNECTIONS.

About once in six weeks is often enough for this inspection if the vehicle is used moderately often.

Fig. 24 shows a sectional plan and elevation of the controller. It is of very simple construction, consisting of a hard wood cylinder 2 inches in diameter, which has four rows of brass screws, each row containing 12 screws. Upon this cylinder 12 flat springs of hard brass or bronze press and make contact with the successive rows of screws as the controller cylinder is moved from one position to another. There are five positions of the cylinder, one of which, however, has no contacts engaged, this being the "off" position.

The frame of the controller is a casting, preferably of alzinc, consisting of a semi-circular top and bottom connected by a ribbed back piece all cast in one. Against the rib at the back of the frame is mounted a strip of fibre ¼ inch thick and 1 inch wide, which is tapped for screws that fasten the brass contact springs in position. Connections are also made to these same screws.

For convenience in making connections between the screw heads on the cylinder it has longitudinal grooves cut at each side of every row of buttons. Small clips of thin sheet copper are fastened under each screw head and soldered to bare copper wires laid in the grooves. The grooves are then filled in with plaster of Paris so that the cylinder presents a smooth surface. Ordinary round head brass machine screws are used for this purpose, and after all connections have been made the cylinder is mounted on its sleeve of steel tubing and placed in the lathe, and all the screw heads turned down to a uniform diameter, pro-

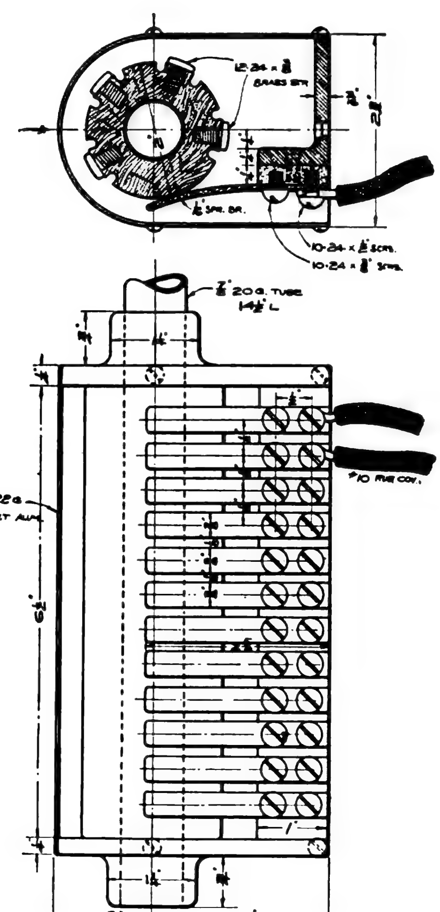

FIG. 24.—SECTIONAL PLAN AND ELEVATION OF CONTROLLER.

jecting about 1/16 inch above the surface of the cylinder.

Fig. 25 is a diagram of connections which is intended to serve as a guide in making the taps on the controller cylinder, and also in connecting the motor and battery leads to the contact springs.

On the first speed all the four battery sections are in multiple, giving 20 volts at the motor. On the second speed the battery is half in series and half in multiple, giving 40 volts at the motor, while on the last notch the cells are all in series, giving 80 volts on the motor and the highest speed. The reverse is just the same as the first forward speed, except that the armature leads are interchanged, thus reversing the direction of rotation.

The Woodwork.

This is of the simplest description; only straight boards are used. The curved surfaces usually seen on automobile bodies would probably be out of question for anyone wishing to construct the woodwork himself. On the other hand, the boards can be shaped on the edges with comparatively little extra labor, so as to make quite an attractive appearance. The shape of the seat panels and the dimensions for them are shown in Figs. 1 and 3. All of the woodwork is intended to be made of ash and looks very well when finished in the natural wood color by putting on two or three coats of orange shellac rubbed down with fine sand paper between each coat. This treatment brings out the natural grain of the wood and while it is simple and inexpensive still gives very good results.

The flooring also is composed of ash boards 6 inches wide and 24¾ inches long and ⅜ inch thick, laid on the lower flange of the angle frame, and fastened thereto by means of 10-24 x ½-inch flat head machine screws, 4 to each board. The flooring is shellacked the same as the other woodwork.

The tool compartment under the seat is provided with a hinged door, which opens from the back and closes with a small drawer lock. In this compartment should also be installed a single-pole, single-throw knife switch, placed in one of the motor armature leads. This is to be open while charging, and also when leaving the machine unattended it can be opened and the door of the compartment locked, when it will be impossible to run the machine without first unlocking the door.

The following is a list of stock required for the woodwork:

Wanted for.	Pieces.	Size.
Seat sides.	2	19x8x⅜
Seat back.	1	32x8x⅜
Seat panels.	2	16½x17½x½
Seat bottom.	1	32x18½x⅝
Front & back tool compt.	2	32x7x⅜
Seat fillets.	2	8x1¼x1¼
Front crosspiece.	1	24¾x2x1⅛
Middle crosspiece.	1	24¾x2½x1¾
Flooring.	12	24¾x6x⅜
Battery trays.	4	23½x3x½
Battery trays.	8	6½x3x⅜

Dressed all over, grain to run in direction of dimension appearing first in above list. Where boards are too wide to be made in one piece they may be "edged up" in two widths.

BOILER ROOM TROUBLE.

BY S. F. HENRY.

In the early part of this year the writer was called in to investigate the boiler-room conditions in a street railway plant in western Ohio. The boiler plant consisted of one 11 ft. x 18 ft., single-ended Scotch boiler with two corrugated Morrison suspension furnaces fitted with Jones under-feed stokers, and four 400-h.p. Cahall horizontal, water-tube boilers, also fitted with the Jones under-feed stoker. The stokers were fed from bins over the boilers, and forced draft was supplied by a large engine-driven fan, the throttle of which was controlled by the steam pressure.

When the writer reached the plant they had had unlimited trouble with tubes burning out on an average of from four to six a day, and it was almost impossible to run a boiler more than one or two days without cutting it out of line to put in some new tubes. As there was not a sufficient number of boilers, it was impossible to keep one out for repairs or cleaning, so when it became necessary to put in tubes the boiler was cut out of line just after the early morning peak, and had to be in line by three or four o'clock in the afternoon. Along with burned-out tubes, it was also found that the retorts of the stokers burned out at a very extravagant rate, owing to the constant shutting down, in which case small leaks in the draft dampers caused the "green" coal in the retorts to burn back and destroy them. When the first boiler was opened to put in new tubes the writer had numerous caps taken off the front headers, which revealed a pretty serious condition of the boilers. In most of the tubes the scale was from ¼ to ⅝ inch thick, and many of the tubes and nearly all the rear headers were completely stopped up, so that circulation through them could not exist. This condition, together with the extreme forcing necessary to keep up steam when the daily boiler was cut out for tubing, to a great extent accounted for the continuous burning out of tubes. The final reason develops one of the objections to the under-feed stoker, which is caused by the fire being localized on such a small area and the intense blast through the tuyeres, especially in a plant in which the engine driving the blower is governed by the steam pressure, for when the pressure gets low the fan speeds up, and the consequent blast on this limited area is almost enough to burn out even a perfectly clean tube. Another difficulty in this particular plant was that the tubes were located too close to the fires, further increasing the bad effect of the blast. How serious this is can be judged from the fact that while forcing for the peak of the load between five and seven o'clock calculation from the amount of coal burned in one furnace showed a fuel consumption of about 175 pounds of coal per square foot per hour.

These conditions, and water with about 90 grains of calcium and magnesium carbonate and sulphate in solution, which was taken from an artesian well, are those which confronted the writer when he took charge of the plant. Of course, it will be evident that the first thing to be done was to clean out all the boilers thoroughly, but the question was how to do it, as it was impossible to keep one boiler out of line because of insufficient boiler capacity when in that condition. The method adopted was as follows: Each time a boiler was cut out, while the boiler-makers were putting in the new tubes a second gang of men was put to work at "turbining" the two or three lower rows of tubes and cleaning off the soot from the outside of the tubes, the back connections and from behind the rear headers and mud drums. In this way, by increasing the heating surface and getting out all the buckled tubes, by the end of two weeks the boilers were in such shape that it was possible to run with only three of them, and the increased efficiency of the boilers and their improved condition greatly reduced the danger of a boiler being disabled within three days, and it was therefore decided to cut one boiler out for drilling.

The drilling was carried out by working a night and a day shift, which, though the tubes were so badly scaled, enabled the work to be done in three and a half days. While the tubes were being drilled a gang was put to work thoroughly cleaning out the front and back headers and the steam and mud drums, while two men were kept busy cleaning off the hand-hole plates. Everything did not go as well as hoped for, and on the second day a tube gave out in one of the other boilers, but a little care in firing carried it through until after the evening peak. It was then shut down and a tube put in, and it was ready for the morning load, though all the other boilers were leaking very severely by the time the clean boiler was cut in again.

After the cleaned boiler was put in line there was no difficulty in keeping up the pressure with two boilers, and from then on the task of cleaning the others was comparatively simple, though considerable difficulty was experienced on account of leaky tubes in the cleaned boiler, since many of the tubes were very thin and started to leak soon after the boiler was cut into line. This was overcome, however, by cutting out the cleaned boiler after the evening load and retubing it at night, carrying the heating load (the only load between 1 a.m. and 5.30 a.m.) with the other two boilers.

A simple expedient which contributed much to the successful completion of the boiler cleaning was the coating of the inside of all the new tubes with graphite and oil, which, although it did not entirely prevent the formation of scale, very materially reduced it; furthermore, the scale which did form did not stick to the tubes and consequently was easily removed. The graphite was almost perfectly intact after removing the scale and was good for another run.

When the writer arrived at the plant the firemen were in the habit of allowing the automatics on the stokers to crowd in a lot of coal, let it burn down and then crowd in another load, and so on, resulting in excessive smoke and loss of economy; it also resulted in burning out tubes and retorts.

for in letting the fires burn down the blast on the tubes was more destructive, and the fires getting low caused them to burn in the retorts. No little difficulty was experienced in making the firemen stoke regularly, making the automatics work constantly, adjusting their speed to correspond to the load, and turning the clinkers over on the side plates before drawing them out. They would also let the fires get too thin after cleaning, and as two stokers were run by one automatic and both stokers would not feed at the same rate, one fire was generally too thick. This was overcome by making the men feed by hand after cleaning and adjust the automatics for the stokers which

BURNT TUBES.

Cause.—Scale, concentrated fire, tube too low, thin fire, soot and water in back connection, action of the "blow" of one tube on the next, irregular expansion and contraction owing to scale and soot which cause the buckling of tubes.

Remedy.—Clean tubes, carry heavier fire, do not let steam pressure become too low, clean the outside of tubes, clean out back connection once a week, keep dirt from behind headers so as not to prevent free expansion.

BURNT RETORTS.

Cause.—Low fires, leaks in draft pipes causing green coal to burn back, removing too much coal and clinker in cleaning fire, shutting down.

Remedy.—Heavy fire, clean clinker from side plates only, use ashes for stopping fires.

SMOKE.

Cause.—Irregular feeding, breaking up fires too often, cleaning fires when green coal is in the fires.

Remedy.—Regular feeding, turning over clinkers on side plates only before drawing out; do not use slice bar too often.

LOSS OF ENERGY.

Cause.—Irregular feeding, drawing out clinkers with green coal clinging to them, pulling out too much fire in cleaning, scale in tubes, leaks causing loss of hot water, excessive forcing.

Remedy.—Constant feeding, turning over clinker before drawing and push off good coal, let all clinker burn out thoroughly before drawing, keep steam pressure up to prevent excessive draft, use a sufficient number of boilers so that forcing is not necessary.

STOKERS.

Faults.—Smoking at hoppers, one feeding faster than others, fire too concentrated, blast on tubes excessive, excessive amount of green coal pulled in cleaning fires, difficulty in cleaning out ashes at back of furnace, burned retorts, cracked retorts, large coal or hard objects breaking stokers.

Remedy.—Burn slack coal only, change stroke of some stokers and work automatics by hand from time to time, build fire-brick arch over retorts or use only with boilers having firebox entirely lined with fire-brick; never use in Morrison suspension furnaces.

fed fastest, and then from time to time work the slow stoker by hand till the fires were about right.

Insisting on these few points and seeing that they were respected resulted in reducing the coal consumption from about 64 or 65 tons per day to about 51 or 52 tons per day, and reduced the smoke at the stack so that most of the time it was difficult to tell by looking at it whether or not the plant was running. Besides the great saving in fuel (this saving was the average before starting to clean the boilers), the saving due to the reduction in tubes burned out amounted easily to $200 per month.

Regarding the stokers, it may be said without hesitation that the under-feed type of mechanical stoker should not be employed in corrugated furnaces, nor with any boilers except those in which the fire is surrounded with a firebrick lining (such as the Cahall vertical), as the blast on the tubes and heating surfaces exposed in the firebox is too intense and is sure to result in constant burning out of these parts. Furthermore, there is great difficulty in keeping the retorts from burning out, and when any coal other than fine slack is employed the smoke coming from the hoppers on the stokers is unbearable and causes loss in economy, because under these conditions it is almost impossible for the firemen to attend to their work properly; in attempting to stop the smoke they will run the automatics by hand and crowd the furnaces so full of coal that it touches the tubes, which was one of the troubles the writer experienced in the present instance. The burning out of the retorts on shutting down was overcome by starting to feed ashes about half an hour before the time to shut down the boiler. This method left the retorts and fireboxes full of ashes when the fire was out, and thus prevented the fire from burning back into the retorts and ruining them.

The foregoing experience is summarized in the accompanying table for the convenience of those who may be interested.

ELECTRICALLY RELEASED BRAKES ON CRANES.

BY ARTHUR B. WEEKS.

The following notes on electrically released brakes and their magnets, for crane service and similar work, are suggested by conditions found in blast furnaces and mills.

All parts of the brake mechanism should be regularly inspected, and repairs attended to as promptly as possible. Usually the one responsible for the motors has the care of brakes and magnets as well. While inspecting and oiling the motors, loose bolts should be looked for, also worn-out cotter pins. Owing to the inaccessibility of some solenoids, this inspection is even more necessary for them. Sometimes wires will be found jarred out of their binding posts, or broken off entirely because of vibrations; sometimes an arc caused by a loose wire destroys a binding-post. Where a wire is found grounded, a piece of Flexduct may be slipped over the wire, which will prove even better than tape.

FIG. 1.—BRAKE SOLENOID.

The application of current to the motor energizes the brake coils, since they are in series with the motor; and the iron core of the brake rigging is drawn up into the magnet coil, which releases the motor brake. Much depends upon the proper adjustment of the brake; if too tight, the motor will heat up very rapidly by taking more current than it should for starting, for there will be a continuous drag on the motor. An ammeter will readily show what the conditions are. If set too tight, the excess current is liable to burn out the motor, as well as the magnet coils.

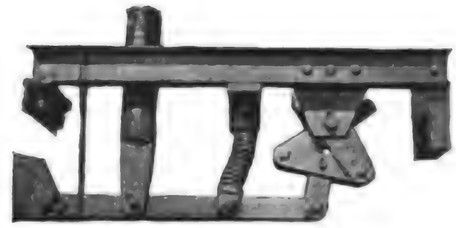

FIG. 2.—BRAKE MECHANISM.

Some mills have neither portable instruments nor ammeters on the switchboard for the several feeders. In the absence of these, inspection must be made, and conclusions drawn from previous experiences. If the circuit is protected by a properly adjusted circuit-breaker or fuse, it is an easy matter to locate the affected circuit. The cause of the excess current must next be determined. This is not always easy; it may be the brake, and it may be due to the careless operating of the motor. The motor itself may be at fault.

The writer has seen heavy pieces of iron hung on brake levers for the purpose of obtaining increased braking effect; at the same time there was an accumulation of oil and grease on the brake band wheel, reducing the braking friction and tending to rot out the leather and cause more trouble. In some mills it is hard to get at things, and a crane can seldom be spared for long; this tends often toward neglect.

When magnet coils are removed for any purpose, they should be tagged with full particulars, and either repaired or reported to the proper parties at once. If not in close touch with the manufacturers, an extra coil should always be kept on hand. Several different sized wire coils should be avoided, one size being kept as a standard. This of course refers to any one motor, each size of wire varying with the size of motor.

Certain conditions in this service require careful study. Conclusions should never be jumped at, but should be carefully thought out step by step. Sometimes these magnets or brake solenoids become excessively hot, burning off the outer insulation, and if wound with cotton covered wire, the entire coil is rendered useless. This is not so if asbestos-covered magnet wire has been used. This wire is coming into more general use since its manufacture has been cheapened. Pure asbestos-covered wire will easily withstand the heat should the wire

become red hot. One make of wire the writer has tested in this way with very good results. It should be specified for all purposes where there is excessive heat, or frequent burnouts. It is valuable for field coils, lifting magnets, arc lamp coils, circuit-breakers, etc., and many armature coils are now being wound with it.

Since the coils for blast furnaces and similar mills are more or less exposed to the weather, it is a very good plan to treat them with a good insulating paint, to exclude moisture; for asbestos is likely to absorb a great deal of water if exposed in moist surroundings. The wire can be obtained from the manufacturers already treated with insulating paint, and is known as "fire-and-wateproof asbestos magnet wire." If this is used, the exterior should be painted with a paraffine black paint.

CORROSION IN BOILERS.

The July *Bulletin* of the Fidelity & Casualty Company contains an interesting note on boiler corrosion. The pipe illustrated by Fig. 1 was removed by one of the company's inspectors from the inside of a boiler. The pipe was connected to the feed pipe supplying the boiler in question. It is, of course, known that corrosion takes place to a greater or less extent in all steam boilers. The feed-water in this particular case was almost free from solids tending to form incrustation or scale, and as far as could be ascertained no great amount of acids was present. The pipe was attacked very much more rapidly than the other internal surfaces. The capricious action of water emphasizes the need of precaution and skill in searching for and determining resultant conditions. In one boiler the action may be along the water line, perhaps heavier at one end than the other. In another the damage may be along

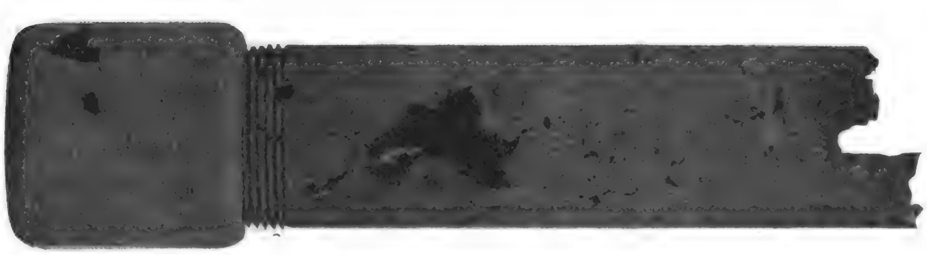

FIG. 1.—EFFECT OF WATER ON BOILER FEED PIPE.

the bottom surfaces or on the tubes, mud-drum or feed pipes. The only way to determine whether a boiler is affected is by careful examination by a competent person. The moderate use of soda appears to be a favorite remedy for corrosion. Kerosene oil is also used with good results. In many instances painting the surface with graphite has proven beneficial. Where the metal is rapidly acted on an analysis of the feed-water should be made to determine what chemicals should be introduced in the feed-water to counteract the conditions causing corrosion.

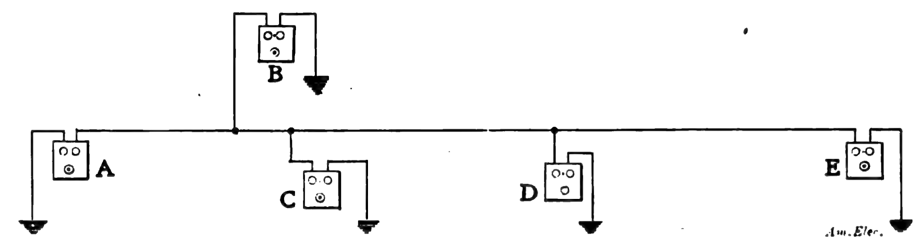
Letters on Practical Subjects

Communications intended for publication in this department must be received at this office not later than the 15th of the month prior to the date of publication.

Heating Greenhouses Electrically.

We should like to obtain information regarding the electrical heating of greenhouses. If any readers of the AMERICAN ELECTRICIAN who have had any experience in this class of work will communicate with us, or if anyone can refer us to parties who have had such experience, we will appreciate the favor. We believe there is an inviting field for electric heating in this branch of business.

FLORISTS' PUBLISHING COMPANY.
Chicago, Ill.



MR. BRAZELL'S PROBLEM IN TELEPHONE CIRCUITS.

Mr. Brazell's Telephone Problem.

Referring to the problem in telephone circuits presented by Mr. J. R. Brazell last month I should think there was too much resistance in the ground connection at Station *C*. At any rate, the output of generator current from that station is not enough to ring all the bells at once. The fault might be in the generator, however; but it is much more likely to be in the ground connection, or in the branch connection from the main line. The bell at Station *A* probably requires more current than any of the others, and being of low resistance probably gets more, but the fact that Station *B* can ring all the bells shows that the branch to Station *A* does not take so very much more current than one of the others. Therefore, as the output from *C* is below normal, the current taken by Station *A*, although perhaps greater than that taken by any of the others, might not be sufficient to ring the series bell at Station *A*.

Reading, Mich. FRANK W. BONE.

The cause of Mr. Brazell's telephone trouble probably is either that the generator at Station *C* is weak, or the resistance of the ground connection there is abnormally high—most likely the latter. It takes so much more current to ring an 80-ohm bell than one of 1,600 ohms that if the resistance in the branch circuit at *C* is very high the generator there cannot supply sufficient current to ring the 80-ohm bell at *A*, although it might furnish enough to ring the others. When Station *C* is called up, its ground circuit needs to pass only 1-20 of the current that it must pass in calling the other stations from there; this accounts for the fact that the other stations can call *C*. A series generator would ring at least ten 1,600-ohm bells on a 20-mile circuit, so that one would expect Station *A* to be able to call up the other stations.

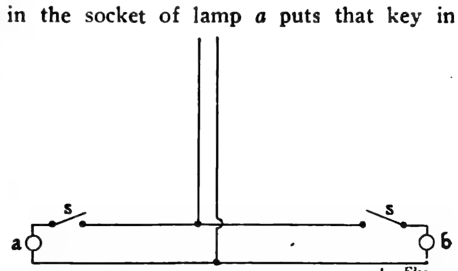
Mesa, Ariz. FRANK W. CERNY.

Mr. Brazell's problem in telephone circuits may be solved by assuming that the generator at Station *C* is too weak to furnish the heavy current necessary to ring the 80-ohm bell at Station A, the 1,600-ohm bells at the other stations requiring much less current. The generators at the other stations, being stronger, are able to ring the 80-ohm bell.

Philadelphia, Pa. W. A. LOVELAND.

Mr. Fuller's Electrolier Trouble.

If the lamp sockets on Mr. Fuller's electrolier are of the Edison type, and if the screw shell is in contact with the main shell of the socket and the turning of the key in the socket of lamp *a* puts that key in



MR. FULLER'S FAULTY ELECTROLIER CIRCUIT.

contact with the socket shell, then a set of conditions exists which will produce the results described in Mr. Fuller's letter last month. I cannot see, however, how such conditions could exist unless the linings were left out of the sockets.

Reading, Mich. FRANK W. BONE.

Referring to the electrolier trouble described last month by Mr. Fuller, I would suggest that the current-carrying parts of the sockets are grounded on the socket shells. I have had the same trouble on old electroliers on which inclined key-sockets were used, and always found the grounds in the sockets.

South Fork, Pa. Alex. M. Cover.

[That the live parts of the sockets were grounded is perfectly obvious; the question is, how and where?—Editor.]

Regarding Mr. Fuller's electrolier trouble I would suggest that the socket switch parts are grounded on the socket structure, so that the two sockets are cross-connected through the electrolier, as indicated by the accompanying sketch, in which the dotted line represents the accidental connection established by the two grounds and the piping. The grounding at the socket *a* occurs only when the key is turned to light the lamp. The sockets are probably unlined and the electrolier may be wired up with lamp cord.

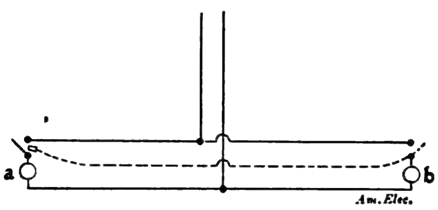


FIG. 1.—MR. HARTMAN'S SOLUTION.

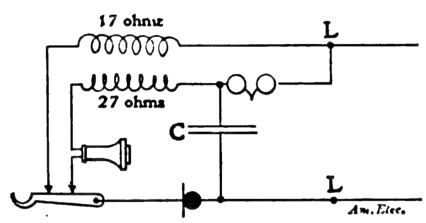
Scranton, Pa. H. F. Hartman.

The Hayes Telephone System.

In Mr. Enoch's letter last month, correcting a statement concerning the Hayes common battery system, there occurs an error which is made by most people who have had experience with the old telephone exchange system using local batteries and have since engaged in work with common battery systems. He states that in the Hayes system the *secondary* of the subscriber's induction coil is shunted by a condenser. The general impression is that the low resistance winding is always the primary and the high resistance section the secondary, but this is not true. In the Hayes system, the winding which, by the action of the transmitter induces impulses in the line, is the high-resistance winding, and its action is obviously primary. Referring to the accompanying diagram of connections, the current from the common battery enters the subscriber's set at the terminals *L L*, and charges the condenser *C;* when the resistance of the transmitter is lowered by the compression of the carbon, during use, the condenser discharges through the local circuit comprising the transmitter, receiver and 27-ohm winding, this impulse inducing a corresponding one in the 17-ohm winding, which delivers it to the line; when the resistance of the transmitter increases, the condenser becomes charged again, and so on. Incoming talking currents, of course, pass through the 17-ohm winding and induce impulses in the 27-ohm winding which act on the receiver.



HAYES TELEPHONE CIRCUIT.

Philadelphia, Pa. W. A. Loveland.

[Mr. Loveland's explanation, while ingenious, is not quite accurate. What actually happens is that a steady current flows through the 17-ohm coil and the transmitter in series when the hook switch is up and no one is talking; talking in the home transmitter produces variations in the line resistance and current which actuate the distant apparatus quite independently of the home induction coil—if the 27-ohm winding were cut out of circuit the operation would not be disturbed. Incoming currents act as Mr. Loveland mentions, so that when the induction coil *is* in active operation the low-resistance winding is the primary.—Editor.]

Mr. Merrill's Bell Connections.

The accompanyng diagram (Fig. 1) is offered as a solution of Mr. Merrill's problem in bell circuits, published in this department last month. Two-way or double-contact push-buttons are used at the middle station and ordinary pushes at the others. One terminal of each bell is permanently connected to the common return wire from the battery. Depressing push-button *1* connects the other terminals of all three bells to the battery through the annunciator drop *a;* depressing the button *4* does the same through the drop *c*. Depressing button *2* connects the terminals of bells *A* and *B* directly to the battery, and depressing the button *3* does the same with the + terminals of the bells *B* and *C*. The annunciator drops must, of course, have very low resistance windings.

Washington, D. C. N. P. Bethel.

[The same solution was supplied by Edw. R. Fisk, West Springfield, Mass.—Editor.]

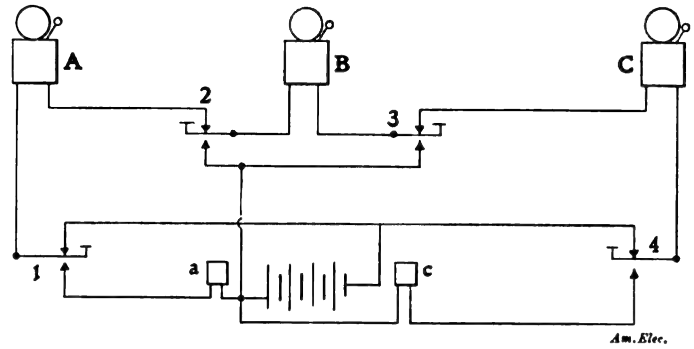


FIG. 2.—MR. BONE'S SOLUTION.

Mr. Merrill's problem can be solved by the arrangement shown in the enclosed diagram (Fig. 2). The push-buttons are all of the two-way type. Depressing No. 1 puts all the bells in series with each other and the drop *a* and the battery; depressing button *4* does the same, except that the drop *b* is included instead of *a*. Button *2* connects bells *B* and *C* in series with each other and the battery, and button *3* makes the same connections for bells *A* and *B*.

Reading, Mich. Frank W. Bone.

[The same solution was furnished by Alex. M. Cover, South Fork, Pa.; Edw. R. Fisk, West Springfield, Mass.; H. F. Hartman, Scranton, Pa., and H. C. Storm, New York.—Editor.]

The enclosed diagram (Fig. 3) is submitted as a solution of Mr. Merrill's problem in bell circuits. All of the push buttons are of the ordinary single-contact variety. Depressing No. 1 completes the series circuit through the three bells and battery

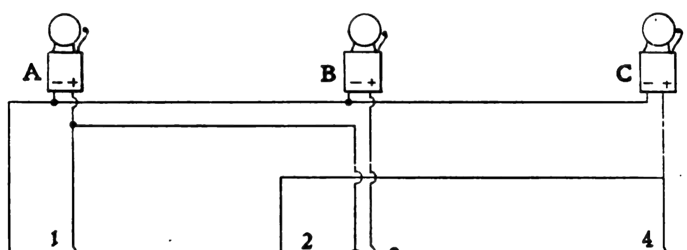

FIG. 1.—MR. BETHEL'S SOLUTION.

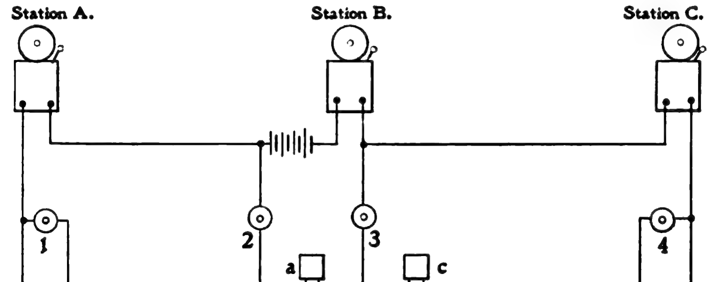

FIG. 3.—MR. HANSON'S SOLUTION.

by way of the drop *a* and the wire *z*; depressing the button *4* does the same through the drop *c* and wire *y*. The button *2* puts the battery and bells *B* and *C* in series through the wire *z* direct, and the button *3* connects the battery and bells *A* and *B* in series through the wire *y*. This arrangement could be used for vibratory signals by making the bell *B* a vibrating bell and the other two single-stroke bells.

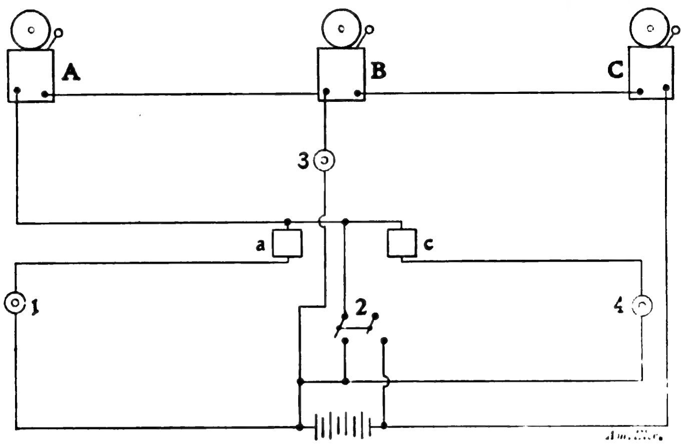

FIG. 4.—MR. WILCOX'S SOLUTION.

State Farm, Mass. W. G. HANSON.

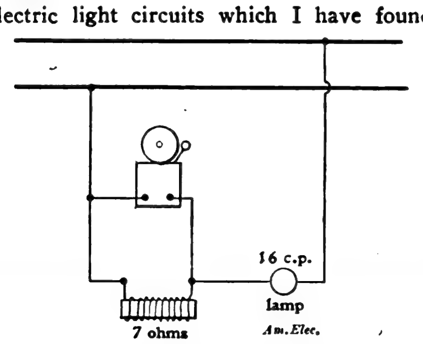
[This solution was also supplied by Edson J. Nash, Ontario Centre, N. Y. It is identical with that of the author, Mr. Merrill.—EDITOR.]

The accompanying diagram (Fig. 4*) shows one way of meeting the requirements of Mr. Merrill's problem. The button *2* is a double-contact (but not a two-way) push; the others are ordinary single-spring buttons. Pressing button *1* connects all the bells and the drop *a* in series with the battery. Pressing button *2* connects bells *A* and *B* in series with the battery; button *3* does the same with bells *B* and *C*, and the button *4* puts all the bells and the drop *c* in series with the battery.

Scottdale, Pa. E. A. WILCOX.

Bell Operation from Lighting Circuits.

The accompanying diagram illustrates a method of operating electric bells from electric light circuits which I have found very satisfactory. The resistance across the terminals of the bell (when the button is closed) consists of about 20 to 25 feet of No. 21 German silver wire; the lamp is an ordinary 16-c.p. incandescent.



BELL OPERATED ON LIGHTING CIRCUIT.

Zanesville, O. ALEX. WEINBERG.

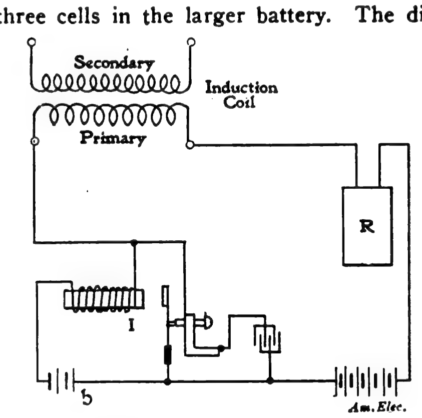
* A line is omitted in the engraving connecting the right-hand terminal of the bell *B* to the right-hand terminal of switch *2*.

Induction Coil Operation.

The method of controlling the excitation of an induction coil that is illustrated by the enclosed diagram is offered as an original and possibly useful "kink" for the benefit of other readers. The interrupter, *i*, is entirely separate from the induction coil and is operated by the small battery *b*. A water resistance, *R*, is in series with the main battery, interrupter contacts and induction coil primary, and serves to regulate the strength of the primary current; a much smoother gradation is obtainable with this than with any multiple-contact rheostat. The current from the interrupter battery and that from the exciting battery flow in parallel through the interrupter contacts when they are closed, the two batteries being opposed. The condenser is in shunt to the contacts, as usual.

Los Angeles, Cal. ROY C. JACKSON.

[The arrangement shown has the disadvantage that when the interrupter contacts open, current from the large battery will continue to flow through the interrupter magnet and the induction coil primary, though this current will, of course, be reduced by having to pass backward through the small battery; if the two batteries have two and five cells, respectively, this reduced current will be that due to the surplus of three cells in the larger battery. The difference between the exciting current when the contacts are closed and that when they are open will, therefore, be considerably less than if a single battery were used and the interrupter magnet connected in series with the primary of the induction coil.—EDITOR.]



INDUCTION COIL OPERATION.

A Problem in Mechanics.

The accompanying sketch represents a plank 10 feet long, weighing 10 pounds (a pound per foot of length) and supported on two knife edges, as shown. At one end, 2 feet of the plank projects beyond the near support, and at the other, the overhang is 3 feet long. The problem is to determine the amount of weight or downward pressure on each of the supports.

Colton, Cal. L. P. BRODE.

Mr. Wolf's Telephone Trouble.

I think the cause of Mr. Wolf's telephone trouble is as follows: While raising the hook switch at *B* does cut out *A* in a way, he still has his receiver between two condensers on one wire. The charging current of these condensers is enough to give indistinct conversation. His trouble at station *B* is probably due to low insulation between the three wires. A telephone receiver is so sensitive that in experimenting with it one finds many things that are quite puzzling. If one terminal of a receiver be connected to the secondary of a small medical coil and the other receiver terminal be held in one's hand, the buzz of the vibrator can be heard, even when everything in circuit is highly insulated. The observer's body takes enough charging current to operate the receiver.

Mesa, Ariz. FRANK W. CERNY.

The July Problems.

In answer to the several questions published in the July number, I wish to suggest to Mr. Miller, in respect to his faulty electrolier, to examine carefully the socket at the lamp *b*; in so doing I believe he will find his trouble.

Mr. Brazell's telephone trouble looks like a weak generator at Station *C*, providing the distances between the different stations are approximately the same. If he has not already made the test I would suggest he change generators with Stations *B*, *D* or *C* to make sure.

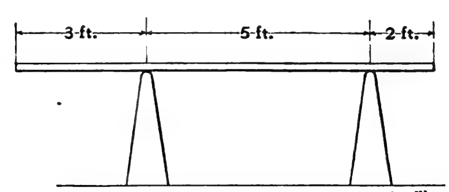
As to Mr. Wolf's telephone trouble, I recommend good insulation for those lines running outside. This, I believe, would clear his trouble, as a very slight leak between wires No. 2 and No. 3 would produce the effects mentioned.

Bad connections are, no doubt, the cause of Mr. Parrish's trouble. The Gamewell fire alarm people, as a rule, turn out splendid apparatus. I believe by throwing battery on the lines and testing with an ordinary telephone receiver a great deal of the trouble would be located.

Washington, D. C. N. P. BETHEL.

Mr. Loveland's Criticism.

In answer to Mr. Loveland's remarks as to my telephone signaling diagram, shown in the June number, I beg to say that in some cases ring-overs will occur and I believe in all cases should the party being rung remove his receiver from the hook others parties would be signaled unless a special relay is inserted in the ringing circuit to operate under certain line resistance. However, I think Mr. Bone's solution



PROBLEM IN MECHANICS.

would be satisfactory. As to the push-button and bell arrangement, I leave that to other readers; I've never tried such an arrangement. I realize it would hardly stand the underwriters' test; I merely suggested it as a possibility. I enjoy these criticisms. They compel one to gain knowledge that otherwise would never be thought of, and I also find such knowledge very beneficial.

Washington, D. C. N. P. Bethel.

Alternating-Current Power Measurement.

It is desired to measure the power output in a three-phase, 2,300-volt, delta connected system. Three recording wattmeters are to be used in conjunction with current and potential transformers. The wattmeters have a rating of 5 amperes, 220-volt; current transformers have a ratio of 160:1 with 5 ampere secondary and potential transformers have a ratio of 10 or 20:1. Give and explain diagram of connections and develop the constant for the meters. In case the meter constant proves to be an awkward number to handle, what can be done to make same an even number without altering the ratio of the current or potential transformers? I will appreciate any suggestions that other readers may offer.

Oakland, Cal. S. J. Lisberger.

Mr. Parrish's Difficulty.

Regarding the inquiry of Mr. Parrish in the July issue as to the trouble on his fire alarm system at Great Barrington, Mass., I beg to say that he answered his own inquiry at the outset of his letter when he said: "The wires were not soldered at any of the connections and the work was performed in a very slipshod fashion." Poor joints in the line will account for everything that has happened. A 20-ohm magnet, such as is used in most fire alarm indicating devices, will retain its armature with less than half the normal current of 10 milli-amperes; but when once released it cannot "pick up" with such a small flow of current. A bad joint in the line will do no harm if undisturbed, and very often it will permit the normal current to flow; but when once the circuit is opened, upon again closing it the resistance of this joint will usually be found to have increased enormously. The action is somewhat similar to that of the anti-coherers used in wireless telegraphy.

It can easily be seen that with the starting of the gear train in a fire alarm box and the opening and closing of the circuit through the fingers and break wheel, or similar devices in the box, the bad joint will permit the first blow and perhaps others; but its resistance is constantly varying and some signals will be transmitted correctly while others will be lost, thus causing entirely different spacing and consequently wrong box numbers.

Your correspondent will continue to have this trouble as long as he has a single bad joint in his line. The only remedy is to solder or sleeve them all. Fire alarm apparatus is usually well made, and with ordinary care can be relied upon, but slipshod installation of it is, to my mind, little short of criminal. Not only property but lives often depend upon its proper action, and to spend money upon anything but the best for everything connected with the system is a public outrage.

I would venture to suggest that if the Great Barrington fire alarm system is not provided with a first-class voltmeter and millammeter, but relies upon a galvanometer to ascertain the condition of its battery and line, as too often is the case, it should at once discard the latter instrument and purchase the two former. Periodical readings of both voltage and current will tell the story of the poor joints in an unmistakable manner. I would also suggest that if the superintendent of the system in question will join the International Association of Municipal Electricians he will be enabled to keep in touch with men who have devoted much time and thought to improvements in this branch of work and whose experience will be valuable to him.

Rutherford, N. J. Walter M. Petty.

Difficulty in Paralleling Two Three-Phase Generators and the Cause.

The following incident reveals some reasons why it is hard to get two generators together on the same bus line; the fault of this case being purely mechanical.

We had two 800-kw. three-phase railway units installed, and the writer was urged to get them into operation as soon as possible. These generators were each coupled to a 1,200-h.p. cross-compound engine of a well-known make. On starting these units it was found that the regulating weights on the governors would have to be taken off in order to get the speed called for, 94 r.p.m. This permitted the units to be thrown together and operated in parallel; but after a time, however, it became difficult to hold them together, the high-tension switches opening because the machines were not in synchronism.

The offending unit was detected in the following manner: There would be a large variation in the receiver pressure and when throwing the generators together the receiver pressures had to be as near the same as possible. The offending unit became more sensitive and began to lag on heavy loads, producing cross feed on the generators. All joints and pipes were examined for leaks, but were found tight. The low-pressure piston heads were also examined and found in good shape. An indicator was ordered, but before it arrived the seat of the trouble was revealed; the high-pressure piston rod carried out with it a yellow substance combined with cylinder oil. The unit was shut down as soon as possible and the cylinder head was taken off. The follower plate was next removed and we discovered a broken ring and broken studs. The system of packing used was entirely new. There were two large phosphor-bronze rings with a steel spring ring within these to set them out and jack screws to hold them in position. Three bearing shoes were provided on the bottom side to carry the weight of the piston head. The shoes bore against steel ring and were adjusted by jack screws, the other ends of which were in a plate set in recesses at the boss on the spider. The follower plate did not bind these rings tight, but allowed for adjustment. The jack screws were of phosphor-bronze. In this case the bottom jack screw had broken, allowing the spider or piston head to drop, breaking the large packing rings in two places. This was the cause of the behavior of the engine and receiver trouble. A bull ring with cast-iron spring rings was ordered to be put in place of the broken rings and the units placed in operation as soon as possible, these units being in constant demand.

A short while after, the other engine began to show the same symptoms as the first, and in the meantime another bull ring had been ordered and we were awaiting its delivery. The day before it arrived a thump was heard in the high-pressure cylinder of this unit, which sounded as if everything had been smashed to pieces. The unit was disconnected, the cylinder head taken off, and an impression was seen on the cylinder head as if a substance had been compressed. When the piston head was brought to the back end of the cylinder there was a hole in the follower plate and a piece of bronze was also found mashed flat. Further examination of the exhaust valve and seat showed that this bronze bolt had passed to the exhaust port and the valve had cut a part of it off, twisting the stem. On removing the follower plate the same conditions were seen to exist as in the first engine with the exception of the hole in the follower plate. When one of the jack screws broke it fell down and as the piston head travelled back and forth this bolt hammered a groove in the iron about five inches long, half way through the plate; then, for some cause or other, it shifted its position to a point where the iron was probably softer and cut a hole diagonally through the iron about an inch and a half in diameter and got out with the above results. The hole appeared to be as if rolled; it was smooth—a case of soft metal cutting through a harder one. The bottom studs were broken in two pieces and ground into balls. The large rings were broken in three places. The new bull ring and follower were put in and this was the end of that method of packing.

As constructed, the slight clearance between the shoe carrying the weight of piston head and follower caused it to vibrate back and forth with the result that this continued action broke the jack screws. After the repairs to the engine were made the matter of regulating weights was taken up and pulleys of smaller diameter were put on the governor shaft, which caused the engine to run at 96 r.p.m. without the weights. After the weights were put in position and adjusted the engines were brought down to a speed of 94 r.p.m. Since the change the generators can be thrown in parallel without any trouble.

Osborn, O. H. C. Reagan.

Questions and Answers

Inquiries not accompanied by the name and address of the inquirer, will not receive attention.

Please give data for an induction coil to give a 3-in. spark when supplied with alternating current at 110 volts and 133 cycles. H. E. B.

We regret that we have no data for such a coil.

How can a three-wire circuit supplied from a single 250-volt dynamo be balanced when some lamps are turned off on one side of the middle wire? J. R. W.

Either by installing a motor-balancer or by using a three-wire generator, which is equipped with autotransformers for balancing the circuit.

What is meant by a 7 x 6 x 8 single acting pump? (2) What is the relation between the power factor and the efficiency of an alternating-current motor. G. R. M.

A pump having a steam cylinder 7 in. in diameter, a water cylinder 6 in. in diameter and a stroke of 8 in. (2) There is no direct relation; a low power factor, however, reduces the efficiency by increasing the copper loss for a given output.

Is a special rheostat necessary for an alternating-current motor, or can the same rheostat be used as with a direct-current motor? H. C. McI.

The rheostats are entirely different in construction and application; they are somewhat similar in general principle only, being employed to keep down the initial rush of current. A direct-current rheostat, therefore, would be useless for starting an alternating-current motor.

How many square inches of tinfoil will be required for a condenser to be used with an induction coil having a core 1¼ in. in diameter and 10½ in. long, a primary winding of two layers of No. 15 wire and a secondary winding of forty layers of No. 30 wire? M. M. H.

Use sixty sheets 6 in. by 10 in. Your coil, however, is not well proportioned; eight pounds of No. 36 silk-covered wire will give much better results; the core should be 2 in. longer and the primary wire should be No. 12 or No. 13.

What is the inductive effect upon two parallel wires carrying alternating current? (2) What is the effect when the wires are in separate conduit pipes? (3) How can induction troubles be overcome? H. B. R.

It is a counter e.m.f. produced by the magnetic field set up around each wire by the alternating current in the wire. The farther apart the wires are, the greater the inductive effect. (2) If the conduit is iron, the effect is greatly enhanced and may easily render operation impracticable. (3) By putting both wires in a single conduit pipe.

How can I test a T.-H. wattmeter for accuracy, having only a bank of lamps, a voltmeter and an ammeter? (2) Can two or more transformers of different capacities be operated in parallel at both the primary and secondary terminals? E. A. T.

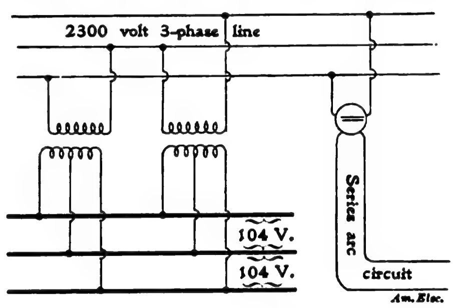
Connect the wattmeter, the voltmeter and the ammeter in circuit with the lamps in the usual manner and supply the lamps with current at the proper voltage for one hour. Watch the voltmeter and ammeter to make sure that no variation in the voltage and current occurs. Multiply the voltmeter reading by the ammeter reading and the result will be watt-hours; take the reading of the wattmeter and compare it. (2) Yes; provided the two are of the same type.

Does an old incandescent lamp take more current than a new one? (2) Why does the current taken by a lamp vary with service? (3) Why do electric lighting companies make a practice of changing their customers' lamps after they have burned a certain number of hours? W. W.

No; it takes less current, but takes more current per unit of light emitted because the illuminating power decreases more rapidly than the current "consumption." (2) Because the resistance of the filament increases during the period of service, due to the gradual wasting away of the carbon. (3) Because the candle-power has become so reduced at that point that the illumination is unsatisfactory, and it pays better to smash the lamps than to have the service poor.

Can incandescent and arc lights be operated from a single three-phase primary circuit, the incandescents being supplied on the three-wire plan from two phases and the arcs from one of the phases of the primary line, as shown by the accompanying diagram? W. T. K.

Not in the way your diagram shows. The plan would be all right, however, if the three-wire secondary mains were cut between the leads from the two trans-



formers so that each transformer supplied its lamps separately. With the connections you show, each constant-potential transformer will short-circuit the other during two-thirds of each cycle, the two phases to which they are connected being one-third of a cycle out of step with each other.

Why can a higher current density per unit of cross-section be employed in an armature winding than in a field winding? (2) What is a safe density for armatures running at ordinary speeds (belted) and in open field magnet frames? (3) Which is preferable for gas engine ignition, a self-exciting dynamo or a magneto, and why? W. T. K.

Because the ventilation is so much better in the armature. There are only a few layers and these move at a high speed, whereas in a field winding there are many layers and the winding is stationary. The radiating surface of an armature per ohm-foot of conductor is much higher than that of a magnet coil. (2) From 2000 to 3000 amperes per square inch of cross-section, according to speed and radial depth of winding. (3) A magneto, because it has a constant field strength regardless of its speed.

What voltage do the Underwriters favor in the lighting of large buildings? (2) Is it considered safe to supply a building with current at 220 volts, or would it be necessary to put in a balancer and supply the current on the three-wire, 110-volt plan? J. T. J.

Any voltage up to 300. (2) The two-wire, 220-volt system is as safe as a three-wire system with 110 volts between the neutral and each outer wire. The latter is a 220-volt system merely divided into two branches, and the division does not make it any safer. As a rule it is preferable to distribute on the three-wire plan, however, because of the higher efficiency of the 110-volt lamp as compared with the 220-volt lamp.

What is the cost of building the electric runabout described in the January, 1903, number? (2) Where can the castings be procured? (3) What is the material and the thickness of the armature core discs? (4) Are the armature coils closed up after winding and both sides put in the same slot? (5) The drawing shows four terminals to the field coil; should there be four or two? H. E. J.

We do not know. (2) We know of no source whence castings can be obtained; it was the intention that the builder should have the castings made. (3) Low carbon annealed sheet metal, not thicker than 25 mils and not thinner than 15 mils. (4) No; each coil should embrace six armature teeth. (5) Two; a drawing of a four terminal coil of the same dimensions was used by mistake.

Please give data for winding the motor described in the July number to operate at 230 volts. (2) What will be the best method of obtaining five speeds from this motor, say 500, 875, 1250, 1625 and 2000 r.p.m.? (3) What will be the power of the motor at each of the speeds mentioned? E. B. B.

It is impracticable to wind the motor for 230 volts without re-designing the armature and commutator, and we are unable to spare the time necessary to do this. (2) The most economical method would be to change the battery connections to give voltages in the proportions required for the different speeds. In practice, however, it would be better to combine fewer changes in battery connections with rheostat control. (3) The power would be roughly proportional to the speed.

How can the torque of a direct-current motor be increased? (2) In rewinding a 220-volt armature for 110 volts what changes are necessary besides increasing the size of the wire? (3) At what point of the piston stroke of a gas engine should the ignition occur? (4) What is the advantage in making the point of ignition adjustable? J. L. V.

If the machine is not too near its sparking limit an armature of slightly larger diameter can be used, thereby reducing the air-gap and increasing the magnetic flux. It will be necessary, in order to obtain the same speed as before, to reduce the number of armature coils, which means, of course, the entire re-designing of the armature and commutator. More explicit instructions cannot be given without complete knowledge of the design. (2) Reduce the number of turns per coil to one-half the present number, using the same number of coils. (3) This depends upon the speed of the engine. In most cases ignition occurs just as the crank reaches the inner center. (4) In order that the most favorable point of ignition may be obtained with different speeds or different mixtures. The higher the speed, the earlier should be the ignition in order to allow time for the mixture to become fully ignited before the crank passes the center.

MAGNETIC COUPLING AND SPEED ACCELERATOR.

The Cutler-Hammer Manufacturing Company, of Milwaukee, Wis., has been carrying on experiments for several years in the development of magnetic couplings and accelerators. The Cutler-Hammer Clutch Company has now been organized for the manufacture and sale of this apparatus, and it announces that it has designs and equipment for the manufacture of a complete line of these couplings and accelerators. The magnetic couplings consist of two cast-steel rings mounted concentric with the shafts to be coupled. One of these rings has an annular groove, in which the magnetizing coil is securely fastened, the other ring acting as the armature or keeper. A cross-section of the two members shows the well-known form of a horseshoe magnet and its keeper. This device is applicable wherever the shafts to be coupled are at rest

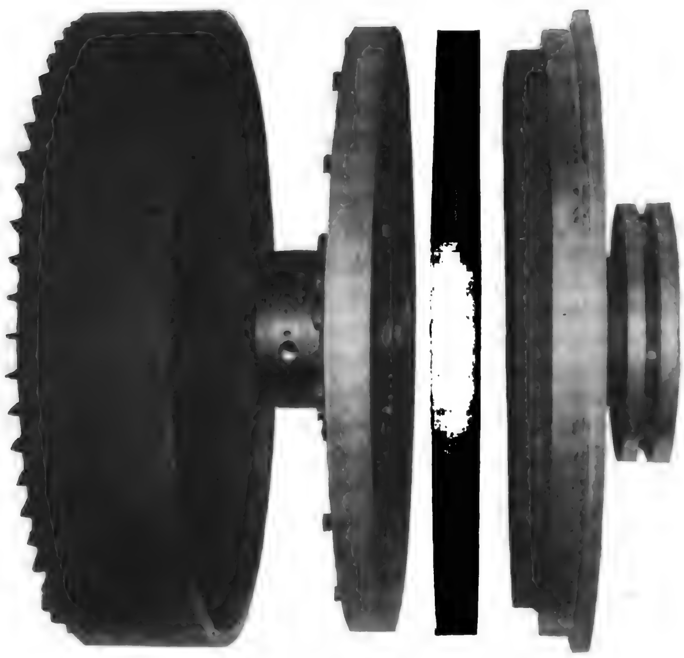


FIG. 1.—PARTS BEFORE BEING ASSEMBLED.

or both running at the same speed when the coupling takes place. They can also be used to cut out a machine or section of shaft when in rotation, giving, it is claimed, a prompt and absolute release regardless of load. The magnetic speed accelerators are used for the same purpose as the ordinary friction clutch, except that they have a much wider range of application. The torque in these clutches is the sum of two components, one due to friction and one due to eddy currents induced to the armature plates, by the magnetism of the field, which is specially constructed to secure this result. At the moment of starting the induction component or torque is a maximum, dropping off as the driven member attains speed. In starting up a load with the ordinary friction clutch it is a noticeable fact that the pressure on the operating lever is eased the moment the load begins to move, in order to obtain a smooth start. In the accelerator this is accomplished automatically by the dropping off of one component of the torque, the result being a remarkably smooth acceleration, which can be controlled, if desired, by means of a rheostat. In practice these accelerators find their readiest appli-

FIG. 2.—FIELD IN THE ROUGH.

cation to that class of service where it is desired to control moderate or large-sized units by some form of automatic device, such as a float switch, relay or electrical

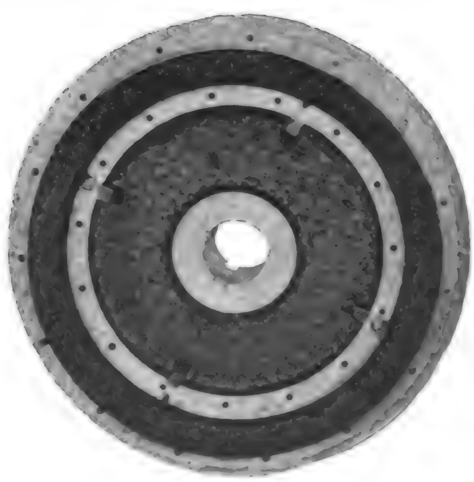

FIG. 5.—BACK PLATE WITH COIL.

contact of any kind. For most work they can be thrown directly across the line without danger from shock or jar, as it is practically impossible to produce a sudden jerk with them. The simplicity of their construction renders them easily balanced for speeds much higher than that for which the

FIG. 3.—FIELD BABBITTED.

ordinary clutch is available. The small currents used in the magnetizing coil results in a simple and cheap controlling apparatus, two amperes being sufficient to control a 100-h.p. unit at the ordinary speed. They are designed and built for heavy service, and ample wearing surface is provided, so that no adjustment for wear is necessary.

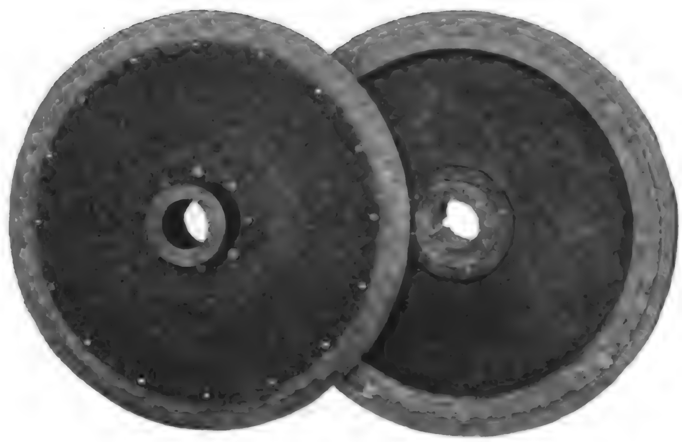

FIG. 4.—PARTS OF MAGNETIC COUPLING.

In connection with gear trains this device is also used to operate a machine at differ-

FIG. 6.—BACK OF FIELD.

ent speeds, and this arrangement has been proven very satisfactory in practice. The principles of design and construction, as well as many applications of these accelerators, are protected by patents.

New Apparatus and Appliances

HASSEL LIMIT SWITCH.

Fig. 1 herewith shows the general features of the Hassel limit switch for electric cranes brought out by the Rex Filter Manufacturing Company, of Pittsburg, Pa. The purpose of the switch is to prevent such conditions on electric cranes known as running block to block. Modern electric cranes equipped with two and sometimes three hoisting motors are operated by one crane

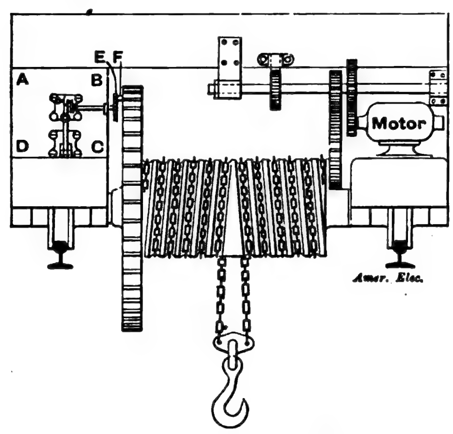

FIG. 1.—HASSEL LIMIT SWITCH.

man from his cage. It frequently happens that two of these motors are set in operation at the same time, one possibly with load and the other more usually without load. Through carelessness one is allowed to operate, attention possibly being diverted by the other, until it runs too high and blocks and hook are drawn together. Before it is noticed the accident occurs which results in a bent shaft, gears broken and other parts injured. The part the Hassel limit switch plays when installed, is to break the current at the critical moment. Fig. 2 illustrates the manner of attaching the switch, *ABCD*, to the crane. Each time the hoisting drum on the crane makes

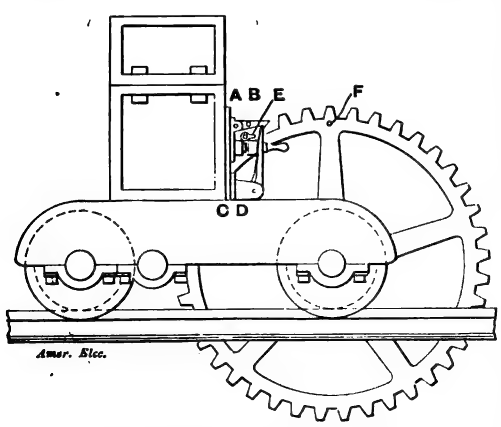

FIG. 2.—HASSEL LIMIT SWITCH.

a revolution, a pin, *F*, engages the star wheel, *E*, and moves it one tooth forward. The star wheel is attached to a shaft, at the other end of which is a tripper. When the drum has made a prearranged number of revolutions and consequently moved forward the star wheel a like number of cogs, the tripper on the shaft opens a lock and the circuit is broken. If, however, the danger point is not reached and the drum is reversed, the star wheel and tripper shaft likewise reverse and the contact is not broken. To accommodate the number of drum revolutions necessary to bring the hook from the floor to the block a star wheel with a corresponding number of teeth is used. Gears to double the revolution of the shaft are introduced when over fifteen turns of the drum are necessary to wind up the chain.

NEW ENGLAND DYNAMOTOR.

The dynamotor illustrated herewith represents a peculiarly handy machine for use in charging motor batteries, or for such other purposes as may require the transformation of direct current from one voltage to another. As will be noticed, it is of the cradle type, the armature being mounted in a yoke or cradle, entirely independent of the field frame, and removable therefrom without disturbing the bearings. Owing to this peculiarity of construction the machine can, of course, be assembled for support either on the floor, or from a wall or ceiling, and has this ad-

FIG. 3.—NEW ENGLAND DYNAMOTOR.

vantage over the bracket type, in that it is impossible for the bearings to get out of alignment when changing from one form of support to the other. The machine illustrated was designed for the operation of a large X-ray outfit, and is intended to deliver 30 amperes at 110 volts on the low pressure or secondary side, using 220-volt current at the primary. The New England Motor Company, of Lowell, Mass. ,the builder of the machine, makes a complete line of these dynamotors.

NEW POLYPHASE INDUCTION MOTOR.

The Westinghouse Electric & Manufacturing Company has placed on the market a new type of polyphase induction motor known as type CCL. These motors are manufactured in sizes ranging from ½ to 75 horse-power, and are wound for operation on two or three-phase circuits at voltages of 200 and 400 for all sizes except the ½ horse-power size. The sizes from ½ to 5 horse-power, inclusive, are also wound for 100 volts. The frame of the motor consists of a solid, cylindrical, cast-iron yoke to the ends of which are bolted brackets which carry the bearings. These brackets are open so as to provide good ventilation, and may be fastened to the frame in any of four different positions, making the motor suitable for floor, wall or ceiling mounting. Motors up to and including 5 horse-power have solid brackets and bearings, with slotted holes in the feet for adjusting the tension of the belt. Larger machines have the brackets and the bearings split horizontally, greatly facilitating the removal of the bearings, should this become

FIG. 4.—THREE-PHASE TYPE CCL MOTOR.

necessary. Belt adjustment on these motors is made by tension screws, which shift the motor on a cast-iron bedplate. There are no wearing parts on the machine except the bearings, and as these are of ample dimensions with a light rotor and flooded lubrication maintained at all times by means of oil rings, the wear is exceedingly slight. The magnetic circuit consists of circular laminations of sheet steel, securely keyed into the cast-iron frame. Terminal leads are brought out at the base of the frame, held in a cast-iron cleat. Hand connectors or knuckle joints, such as are supplied with railway motors, are used to connect the motor to the supply circuit. The rotors of all CCL motors are of the squirrel-cage type. The winding consists of square copper bars lying in partially closed slots and bolted at the ends to metallic rings of ample cross-section to dissipate the heat generated in them. For the ½-h.p. motor round bars are used and are riveted to brass or copper rings at

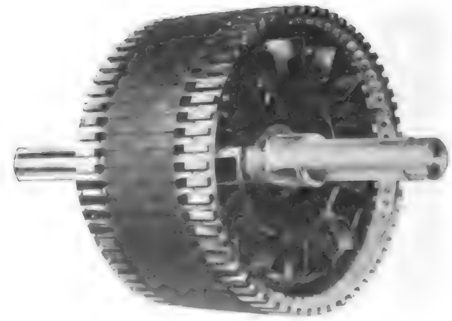

FIG. 5.—ROTOR OF TYPE CCL MOTOR.

each end. The design and principles governing the construction of these motors are particularly favorable to maintaining good efficiencies at low loads, which insure a high all-day efficiency, as in general service

motors may operate at light loads much of the time. The motors are provided with liberal bearings and shafts, and adjustment of the bearings is said to be unnecessary.

ENGINE INDICATOR AND OVERLOAD ALARM.

Fig. 6 herewith illustrates a device recently designed by J. F. Shreffler, of Chicago, Ill., the purpose of which is to give a constant reading of the load on the engine in plain figures. It is also arranged to sound an alarm should the load exceed any predetermined maximum. The indicator is permanently attached to the engine and is operated by affixing an indicating finger to that part of the valve or governing mechan-

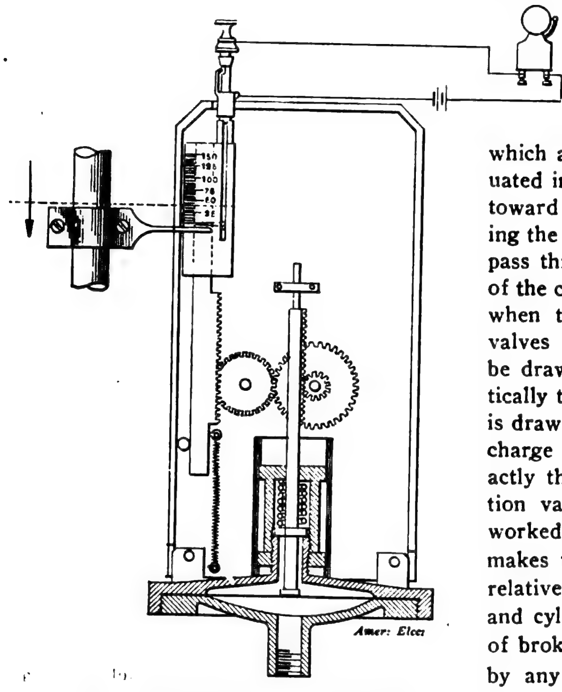

FIG. 6.—SHREFFLER ENGINE INDICATOR.

ism, such as the knock-off rod of a Corliss engine, which has a movement varying uniformly with the load on the engine. The indicating finger travels over a graduated scale, which is caused to move longitudinally as the steam pressure varies, by means of the gears shown which are acted upon by the rod in contact with the diaphragm plate at the bottom. This diaphragm is connected to the source of pressure and a connection is made at the opposite side of diaphragm to an exhaust pipe for condensing engine and those working against the back pressure. The scale plate is made movable to compensate for any variation in steam pressure and the overload attachment is fastened to it. In operation the index finger is placed at any desired figure on the scale plate. If the indicating finger moves over the scale to a point beyond the point at which the overload finger is placed, a rod is displaced, closing an electric circuit and resulting in the ringing of a bell. The scale plate may be calibrated by means of the old style card-tracing steam indicator, and when once calibrated, it is claimed, a simple test can be applied to verify or correct its accuracy due to the wear on the engine's parts.

MOTOR-DRIVEN REFRIGERATING MACHINE.

One of the new types of refrigerating machines built by the De La Vergue Machine Company, of New York, is illustrated in the accompanying engraving. These machines have been produced to satisfy a call for small and medium-sized units employed in plants which draw their power from lighting mains, and for use elsewhere where steam or other power is not available or convenient. They are driven by Morse noiseless chain belting, which allows the motor to be set quite close to the machine, so that the whole unit becomes well adapted to use where floor space is limited. The water jackets, which are of the closed type, perform the function of cooling not only the cylinder walls, but also the oil for lubricating the piston rod. One of the characteristic features of this machine is the arrangement of the valves. Both the suction and discharge valves, which are of the usual poppet type, are situated in a common chamber with their seats toward the center so that the cold gas entering the cylinder and the hot gas leaving both pass through a common port in the bottom of the cylinder. From this it is obvious that when the valve bonnets are removed the valves and springs in their housings can be drawn out of their chambers with practically the same facility that a Corliss valve is drawn out of its valve chamber. The discharge valve housings and seats are of exactly the same length and size as the suction valve housings and seats and all are worked to a system of standards which makes them interchangeable. The peculiar relative arrangement of the valve chambers and cylinder makes it impossible for pieces of broken valves to get into the cylinder if by any chance a valve should break. A further precaution is taken by making the suction valve housing split, which enables the suction valves to be made of one solid piece of metal, and without diminishing their cross-section at any point. Both suction and discharge valves are made hollow, so that their inertia is reduced to a minimum and quick opening and closing necessary for high efficiency is obtained. By utilizing the same port for suction and discharge the clearance is not only halved, but the extremes of cylinder temperature due to entering cold and discharging hot gas are tempered and the usual difficulties due to expansion and contraction are eliminated. The location of the discharge as well as the suction valves allows this type of compressor to discharge large quantities of liquid which may accidentally enter the cylinder, without the dangers incident to similar occurrences in other machines. The valve design of these small and medium-sized units is practically the same as that employed by the company on its large type of horizontal machines.

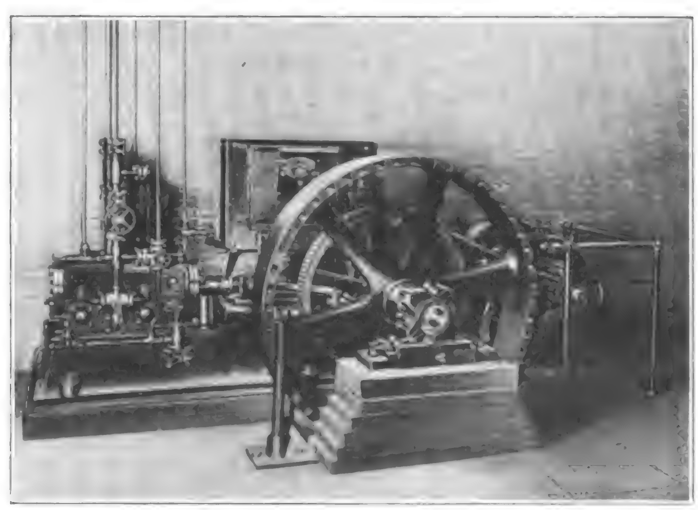

FIG. 7.—5-TON MOTOR-DRIVEN REFRIGERATING MACHINE.

IMPROVED REGRINDING VALVES.

The Lunkenheimer Company, of Cincinnati, Ohio, has made a number of improvements on its regrinding valves. The changes, however, are not at all radical. The weight has been increased, the shape altered and longer screw threads provided. All sizes of the valves now have lock-nuts on the hand wheels, which facilitates the

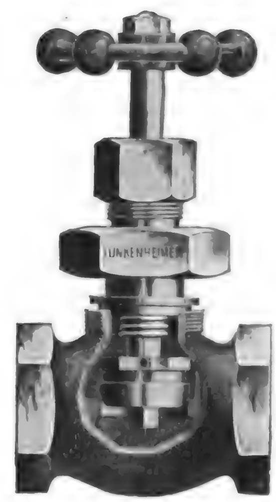

FIG. 8.—LUNKENHEIMER VALVE.

taking apart and assembling of the valve for repairs, etc. Referring to the sectional illustration, it will be noticed that the hub is secured to the body by a union connection which screws over the shell of the valve body. By means of this construction it is impossible for the hub and the body to become corroded together, as the thread which holds the union ring to the body is protected at all times from the action of the steam, the joint being made between the flange on the hub and the neck of the body. This connection also acts as a tie or binder in screwing over the body and tends to make the valve rigid and strong. The disc is held loosely to the stem by

means of a lock-nut, and therefore will adjust itself to the seat readily. The stem is fitted with a strong thread, and the manufacturers state that the valve is very easy to operate. The reason for this is that the hand wheels are so proportioned in respect to the seat opening that no additional leverage need be applied to the hand wheel to facilitate the operation of the valve. To regrind the valve the bonnet ring is unscrewed and the trimmings are removed from the body. A wire or nail is placed through the lock-nut and stem, a little powdered sand or glass and soap or oil are placed on the disc, and the trimmings are again placed in the valve and reground. The bonnet has a small rim or projection on the bottom thereof, which acts as a guide on the inside of the valve neck while regrinding. The seats on the valve-bodies are small when the valves are sent out, which permits of considerable regrinding and is considered an important feature. The valve can be packed under pressure when open or closed, and to pack while the steam is flowing through the valve the valve is opened as wide as possible, when the shoulder at the top of the stem thread forms a seat beneath the stuffing box.

A COMPACT ELECTRICAL GENERATING SET.

A new series of designs of generating sets with direct-connected compound engines has recently been placed upon the market by the B. F. Sturtevant Co., Hyde Park, Mass., of which the 100-kw. size is illustrated herewith. The new series embraces five sizes, ranging from 17½ to 100 kilowatts, which are particularly adapted for marine use or for use under conditions requiring a compact equipment. The designs were made to conform strictly to the requirements of the U. S. Navy, for which a number of sets has been built. The engine has an enclosed frame, with oil-tight doors, easily detachable for access to the moving parts within, so as to provide for splash lubrication; this is assisted by a centrifugal oil thrower at each end of the engine shaft which floods the crank pins, etc. Force feed lubrication is also provided at the other bearing parts and the rod stuffing boxes are rendered accessible from without the enclosed frame. The other features of the design indicate careful study—the high-pressure cylinder has a double-ported piston valve and the low-pressure cylinder a double-ported balanced slide valve, arranged to lift from its seat in case excessive condensation should be present. The cylinders are also protected from water by special relief valves at each end. Rites governors are used which maintain a speed regulation within 1½ per cent. from no load to full load. The 100-kw. size operates at 350 r.p.m. under the steam pressure of 150 lbs. The generator is of the multipolar engine type with compound winding and has a two-circuit armature of the ventilated drum type.

FIG. 9.—COMPACT ELECTRICAL GENERATING SET.

A special feature is to be noted in that a vertical adjustment is provided for the field frame for equalizing the air gap. The pole pieces embody a new construction of wrought iron with cast iron shoes permitting of easy removal for access to the field coils. The armature core is of a new design, which is effective in eliminating hysteresis losses and is still mechanically strong; particular attention was given to the securing of ample core ventilation. Insulation is another factor that has received careful attention, it being guaranteed damp proof and unaffected by temperatures up to 100° C. The brushes are designed for a maximum current density of 50 amperes per sq. in. of bearing surface and are staggered to equalize the wear upon the commutator. The set is subjected to rigid tests after erection, the engine being operated at overload without lagging to detect possible imperfections in the castings. The generators are designed to operate with 50 per cent. overload for short intervals and continuously at 25 per cent. overload, without sparking or undue heating. The electrical regulation secured is such that the voltage does not vary greatly when full load is thrown suddenly on or off.

SMALL VERTICAL HIGH-SPEED ENGINE.

The illustration herewith shows a small vertical engine recently placed upon the market by the American Blower Company, of Detroit, Mich., which possesses unique features of great merit. The engine is fully enclosed, preventing foreign matter getting into the working parts, yet the latter are easily accessible upon the removal of the enclosing plates, by simply turning a milled hand nut. The most remarkable feature of the engine is its oiling system. This is something entirely different from any of the usual methods. The oiling is done by the engine itself, and instead of a drop or two a minute, it is claimed that each bearing has a stream of oil. By referring to Fig. 10 the operation can be easily traced. An eccentric, *K*, on the shaft actuates the plunger, *L*, of the oil pump, *A*, forcing the

FIG. 10.—A. B. C. HIGH-SPEED ENGINE.

oil up through the tube, *B*, into the small strainer, *C*. From *C* it drops into an oil-box through the bottom of which four tubes project. In one side of each of these tubes there is a slot, so that when the oil-

box contains only a small amount of oil, each tube can take its proper proportion. In case the box is full all the tubes get more oil in proportion to the increased height. One of these tubes, *F*, and one on the opposite side, not lettered, apply oil to the guides, the oil dropping into a small oil trough, *G*, from which it runs into the bearing through an oil hole. The cross-head pin is supplied by the tube marked *E*, the oil drops into the cup, *H*, and fills the cavity between the bolt and inside of cross-head pin and the oil grooves. The oil dropping from the cross-head is caught in two pans attached to the inside of the covers. From these oil pans it runs down the inside of the cover, dropping into a cup in the top of the main-bearing cap. Instead of oil grooves at the top and bottom of the main bearing, as ordinarily made, in this system the oil is supplied at the sides where the bearing is cut away at the joint. When the strain from the connecting rod is up, the oil is carried to the bottom of the bearing, but when the load is reversed, there are no oil grooves to carry away this oil. The crank pin is oiled through the tube marked *D*. This tube discharges into a crank oil ring inside the eccentric, *K*, which in turn discharges into the crank-pin oil tube, and flows across the crank-pin bearing. The crank-pin oil ring, in addition to its independent supply, catches the drip from one end of the main bearing. The eccentric is oiled by the drip which it catches from the other end. Not the least difficulty has been experienced in catching the oil thrown off the eccentric strap and the splash from the cross-head has been equally easy to take care of, the outside of the engine being free from oil. A portion of the oil as it drops back into the bottom of the frame drops upon an oil filter and is cleaned and purified. The large base gives the oil an excellent opportunity to cool and settle. The manufacturers have been experimenting with this engine for some two years past, and in connection with their experiments relate an experience which is little short of marvelous. An engine was adjusted and filled with oil on March 10th; up to July 15th no adjustments of any character had been made, and no oil added except to fill the sight-feed cylinder lubricator. It had been operating from fourteen to sixteen hours per day driving a blower, and after the lapse of over four months really needed no adjustment or fresh lubricant, running almost as noiselessly as at first. The builders claim that they expect every engine turned out to operate in an equally satisfactory manner.

TEST OF A DE LAVAL STEAM TURBINE.

Much has been written of late regarding the probable deterioration of steam turbines after they have been in service a number of years and of the probable effect of this deterioration on the steam economy of the machine. Recent tests made by Profs. Edward F. Miller and R. R. Lawrence, of the Massachusetts Institute of Technology, on a 150-h.p. steam turbine dynamo set, which had been in use for the past two years in the plant of the New England

FIG. 1.—DE LAVAL TURBINE WHEEL.

Construction Company, will therefore, doubtless, be of interest.

The turbine was taken apart and thoroughly examined as regards to wear before the test was made, and photographs were taken of the turbine wheel, buckets and pinion, which are reproduced herewith. It will be noted that the wear on all of these parts is practically nil. This machine was installed with the following steam guarantees: 18.7 pounds of steam per b.h.p. per hour at full load, and 19.7 pounds of steam at half load, with a steam pressure of 150 pounds at the governor value and a vacuum of 26 inches at the turbine. The results of the tests show that the turbine is still within the original guarantee, thus proving that whatever deterioration may have taken place has not, to all appearances, affected the steam consumption.

The test was made June 11, continuing from 9 a. m. until 6 p. m., after which the electrical heat losses were obtained in order to determine the absolute brake horsepower. The steam supplied to the turbine for the test came from one boiler; the steam for the auxiliaries and the feed pump supplying this boiler coming from a second boiler. A steam loop was utilized to turn all condensation from the steam main leading to the turbine to the boiler. The amount of steam used was determined by measuring the feed-water. The blow-off pipe and the auxiliary feed pipe were disconnected and blanked. The steam and feed piping were both kept tight, so that there were no leakages to make allowance for, all of the water put into the boiler being used in the turbine and in the calorimeter. The feed-water was weighed in a barrel on a pair of scales sensitive to less than ¼ of a pound under maximum load. The water weighed was run into a small barrel beneath the scales and the feed was taken from this barrel. The quality of the steam was figured from readings taken on a throttling calorimeter placed near the throttle of the turbine. The time

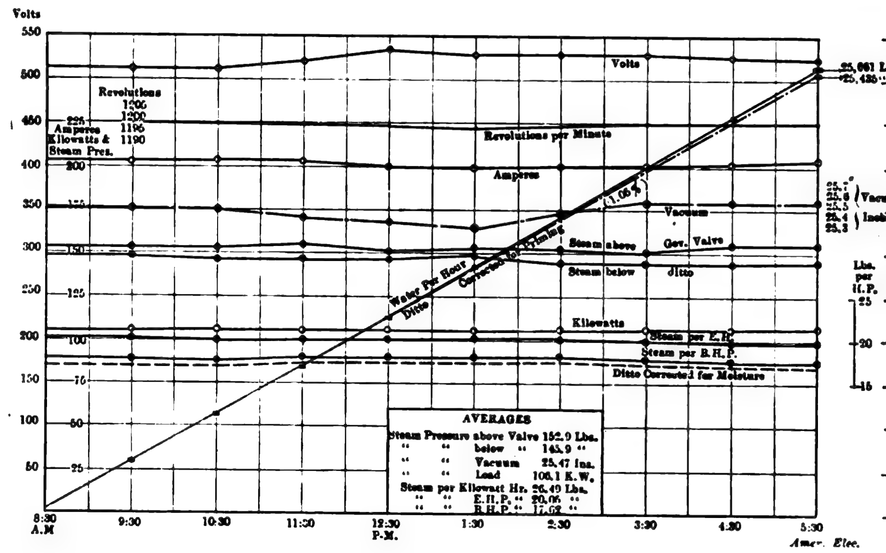

FIG. 3.—TEST OF A DE LAVAL STEAM TURBINE.

this instrument was in use was noted and the amount of steam used by it was calculated by Napier's formula. The orifice used to do the throttling was ¼ inch in diameter. Pressures were taken at the throttle and in the case supplying the nozzles. This latter pressure is beyond the governor and fluctuates with any change of load. Temperatures of the steam at these two places were taken also. It was thought that the throttling by the governor might dry out any slight amount of moisture in the steam

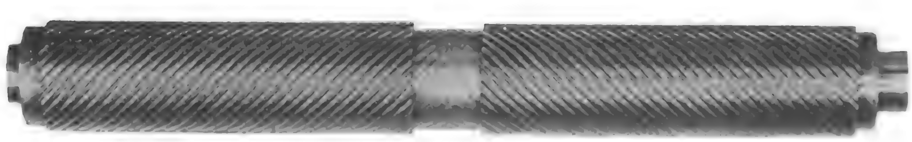

FIG. 2.—DE LAVAL TURBINE PINION.

and that the steam entering the nozzles might be slightly superheated. During this test the throttling was slight and there was but little change in the quality of the steam in passing through the governor valve. The vacuum was measured by a U-tube filled with mercury. The poorer vacuum obtained near the middle of the test was due to low water in the river.

The electrical output was absorbed in a water-cooled rheostat. The load was kept very steady throughout the test and the necessary electrical instruments were inserted for measuring the power. Previous to the test the turbine had been running 45 minutes. The results of the test are tabulated below:

Duration of test, hours	9
Boiler pressure gauge, lbs.	152.9
Boilure pressure below governor valve, lbs.	145.9
Number of nozzles in use	6
Quality of steam, priming per cent	1.05
Barometer, inches	29.90
Vacuum, inches	25.47
Average volts, dynamo No. 1	262.7
Average volts, dynamo No. 2	262.1
Total amperes	202.0
Average total kw. output	106.1
Average total E. H. P. output	142.2
Average total B. H. P. input	160.4
Average number of revolutions per min.	1,200.0
Total steam used for nine hours, lbs.	25,661
Average steam per hour, lbs.	2,851.0
Average steam per hour, corrected for moisture, lbs.	2,826.0
Steam per kw.-hour, lbs.	26.49
Steam per E. H. P. hour, lbs.	20.05
Steam per B. H. P., hour, lbs.	17.77
Steam per B. H. P. hour, corrected for moisture, lbs.	17.62

THE ELECTRICAL COMPRESSOR PLANT IN THE CHICAGO & NORTHWESTERN RAILROAD TERMINAL.

The air power plant at the Chicago terminal station of the Chicago & Northwestern Railroad is a typical example of the best modern practice in the application of electric power to the compression of air for the many purposes of railroad yard work.

The plant is located in a small brick building to the rear of the station, close to the river and adjacent to the extensive passenger yards of the company. This building comprises two rooms, in one of which is located the electrical and pneumatic apparatus.

Alternating current is taken from the main of the Chicago Edison Company and passed through transformers, reducing it to the working voltage. Part of it is used directly on low-voltage alternating circuits, and the remainder is passed through rotary converters or motor generators and delivered as direct current for power purposes.

The air compresser plant is made up of two Ingersoll-Sergeant standard power-driven compressors, of the type designated by the makers as Class "JC." They are duplex two-stage machines, with air cylinders, frames, and bearings, mounted on a solid cast-iron bed-plate, which encloses the horizontal inter-cooler between the cylinders. Both high and low-pressure cylinders are fitted with the standard Ingersoll-Sergeant piston inlet valve, and regulation is secured by a standard choking controller on the low-pressure intake. This device, acting to throttle the air intake passage, is controlled by receiver pressure and automatically regulates the volume of air compressed and consequently the amount of power consumed—to the demand for air from the power system. The compressors run at constant speed, the controller simply varying the effective piston displacement with varying load. The machines have a stroke of 12 inches, with air cylinders 12¼ and 18¼ inches in diameter. At a speed of 130 r.p.m. the free air capacity of each unit is 455 cubic feet per minute. The pressure used in this plant is 70 to 80 lb. gauge.

The sub-base is extended in each compressor to support the driving motors, which are General Electric direct-current machines, rated at 80 horse-power on 220 volts and having a speed of 510 r.p.m. A pinion on the motor-shaft gears directly with the teeth on the compressor fly-wheel, which is of standard weight for machines of this capacity. The gears are protected by proper guards.

Independent concrete foundations are used. Each unit has its own automatic oiling system, fed from a central tank. The drip is recovered and filtered. Sight-feed oilers care for cylinder lubrication. Fig. 1 shows one of the units, of which there are two in operation. An intake duct, supplying both compressors, leads under the floor to the open air and rises beside the power-house, terminating in a screen cover for the exclusion of dust and cinders from the yards.

The discharge pipes from the two units feed an air main leading to the primary receiver outside the plant. Provision is made for draining this receiver. From this point, the line leads to a system of cooling tubes to the west of the power-house, made up of a large upper and lower horizontal header, connected by a number of small vertical pipes. This arrangement, freely exposed to the air, precipitates whatever moisture may remain in the air after leaving the primary receiver; and this water is withdrawn from the lower header. From this cooler, air lines radiate throughout the yard, supplying power to the pneumatic switch and signal system controlling the movement of trains in the terminal track system. Secondary air receivers are also located at suitable places. The air is used almost entirely in this system for switches and signals; but a small portion is diverted to the boiler room, where it is applied in a small air-lift pumping outfit which supplies water to the terminal.

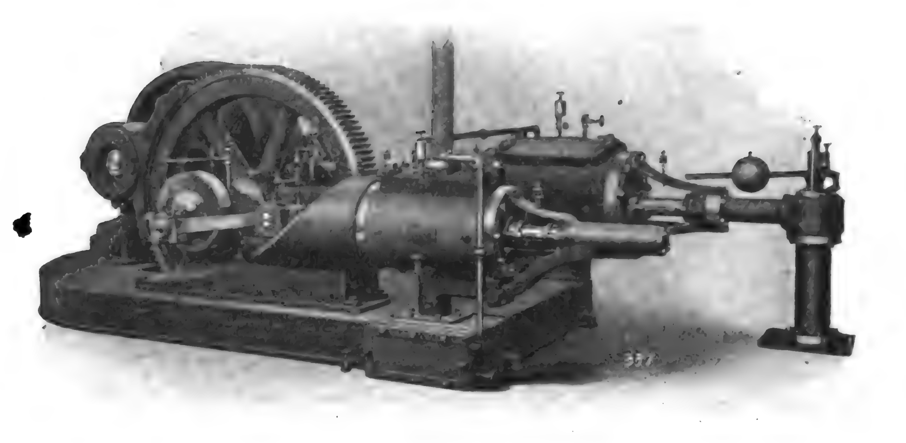

FIG. 1.—MOTOR-DRIVEN AIR COMPRESSOR.

TESTS ON A 2000-KW. CURTIS STEAM TURBINE.

Tabulated below are the results of tests made by Louis Ferguson of the Commonwealth Electric Company, of Chicago, and F. Sargent, of Sargent & Lundy, on a 2,000-kw. Curtis steam turbine at Schenectady, N. Y., on May 3, 1905. The turbine is a four-stage machine designed in 1903 and recently changed in a few particulars as a result of experiments conducted during the past year. The machine conforms as nearly as possible to the standard four-stage machines now being produced, but the builder claims that it is less efficient since the changes made were confined to the buckets, while several other changes, which were desirable, could not be made without entirely rebuilding the machine. All of the instruments used during the test were carefully tested and standardized in New York. The surface condenser used showed practically no leakage, and every precaution was said to be taken to make the test reliable and accurate. The results obtained were as follows:

Full-Load Test:

Duration of test	1.25	hour.
Steam pressure (gauge)	166.3	lbs.
Back pressure (absolute)	1.49	in. of mercury.
Superheat	207.	deg. F.
Load in kilowatts	2023.7	
Steam consump. per kw.-hr.	15.02	lbs.

Half-Load Test:

Duration of test	0.916	hour.
Steam pressure (gauge)	170.2	lbs.
Back pressure (absolute)	1.40	in. of mercury.
Superheat	120.	degrees F.
Load in kilowatts	1066.7	
Steam consump. per kw.-hr.	16.31	lbs.

Quarter-Load Test:

Duration of test	1.	hour.
Steam pressure (gauge)	155.5	lbs.
Back pressure (absolute)	1.45	in. of mercury.
Superheat	204.	degrees F.
Load in kilowatts	555.	
Steam consump. per kw.-hr.	18.09	

Zero Load:

Duration of test	1.33	hours.
Steam pressure (gauge)	154.5	lbs.
Back pressure (absolute)	1.85	in. of mercury.
Superheat	156.	degrees F.
Steam consump. per kw.-hr.	1510.5	lbs.

CROCKER-WHEELER ELECTION AND DIVIDEND.

The officers of Crocker-Wheeler Co., Ampere, N. J., have been re-elected for the ensuing year. The officers are Dr. Schuyler Skaats Wheeler, president; Gano S. Dunn, vice-president and chief engineer; W. L. Brownell, treasurer; G. W. Bower, assistant treasurer. The directors are Prof. Francis B. Crocker, Dr. Wheeler, Messrs. Dunn, Doremus, A. Foster Higgins, Herbert Noble, Thomas Ewing, Jr., F. L. Eldridge and C. A. Spofford. The regular quarterly dividend of 1½ per cent. has been declared and the affairs of the company are reported as being in a flourishing condition.

ELECTRIC LIGHTING AND POWER UNITS FOR EXPORT.

The B. F. Sturtevant Co. has for years made a specialty of high-grade generating sets, with the engine and generator designed each for he other, and combining high efficiency with small space and weight—elements which are particularly essential in machinery built for export. This company now catalogues thirty-six different sizes and types of units ranging from 3 to 100 kw. Each is absolutely complete, and is carried upon a bedplate common to both members of the set. The size and weight of all but the larger sizes are such as to permit of export shipment without the separation of parts, so that the machine stands ready for operation as soon as it is unpacked.

The Sturtevant Company recently made an interesting and somewhat unusual application of induced draft in the plant of the Cleveland Paper Manufacturing Company, Cleveland, Ohio. A special engine-driven fan was installed to produce draft for two horizontal return tubular boilers of 200 horse-power, and force the products of combustion under two other boilers which serve as feed-water heaters or economizers.

A LARGE AUTOMATIC TELEPHONE EXCHANGE.

The Automatic Electric Company recently closed a contract of considerable interest to telephone men. It is for a 15,000 line automatic telephone system for Havana, Cuba. This is to displace the old "Red Telefonica System" of Havana, formerly owned by a Spanish company but now a part of the properties of the Cuban Telephone & Telegraph Company. The latter company has also contracted with the Automatic Electric for a 600 line automatic system for the town of Marianao, Cuba, a suburb of Havana. The initial installation at Havana will be for 5000 lines.

The cosmopolitan character of Havana's population makes the automatic system peculiarly well adapted for use there; it would be necessary for telephone operators to be fairly good linguists in a city of so many nationalities.

Two other contracts recently granted the Automatic Electric Company were for a 250-line exchange at Miamisburg, Ohio, for the Montgomery County Telephone Company, and a 1200-line exchange for the Dakota Central Telephone Company at Aberdeen, South Dakota. These two exchanges will be the first to have the new automatic four-party lines with selective ringing and lockout recently worked out by the company's engineers. This new development of the automatic system attracted much attention at the recent Independent Telephone Convention in Chicago, where it was exhibited for the first time.

THE HAVANA CENTRAL RAILWAY SYSTEM.

The Havana Central Railway Company, Havana, Cuba, has placed orders with the Foreign Department of the General Electric Company, of Schenectady, N. Y., for complete electrical equipment of a net work of interurban electric railway lines radiating from Havana and covering an extensive territory inland. The system will include a central power house in Havana and eight outside sub-stations, together with line material for about 125 miles of trackage and rolling stock for passenger and freight service over the entire system.

The power house in Havana will furnish 5000 kilowatts at 19,000 volts and 25 cycles; three-phase alternating current generators and Curtis steam turbines will be used. The generator e.m.f. of 2200 volts will be stepped up by air-blast transformers to the line voltage. The transmission lines will parallel the various lines of the railway to the sub-stations where step-down transformers will supply rotary converters furnishing 600-volt direct current to the trolley lines and feeders.

From Havana one branch will run southeast through Cuatro Caminos, Lomas de Candela, Guines and Providencia to Rosario, a distance of about 40 miles. Sub-stations will be located at Cuatro Caminos, Lomas de Candela and Providencia. A second line will run from Havana 17 miles south to Bejucal with a sub-station on the line at Santiago de las Vegas. A third line running southwest from Havana to Mariel will have a length of 37 miles and branch lines running north and south to El Carmelo, Santiago de las Vegas and Tuira de Malena amounting to about 30 miles in addition. Sub-stations on the line to Mariel will be located at Marianao, Hoyo Colorado, Guanajay and San Antonio Melena.

The rolling stock for passenger service will consist of twenty-four 30-ton cars, each seating 50 passengers and equipped with four GE-74 motors geared for a maximum speed of 40 miles an hour. The freight service will be handled by ten 40-ton General Electric locomotives equipped with four GE-55 motors geared for a speed of 17 miles an hour when hauling a 300-ton train.

The entire system will have double overhead trolley both in Havana and on the interurban lines. The high potential transmission lines will be designed for a future potential of 30,000 volts to provide for extensions. The transformers in the Havana power house and in the sub-stations are also to be suitable for use at the increased potential.

CRANE COMPANY'S 50th ANNIVERSARY.

The Crane Company, Chicago, celebrated its fiftieth anniversary on July 4th; all of the company's branch house managers took part in the celebration. The branch house managers went all through the factories and were given a dinner and taken to the "White City," where an evening was spent visiting places of entertainment. A trip was also made to Lake Geneva, Wis., where they were entertained by Mr. R. T. Crane at his summer residence, and on July 6th the company gave to all its employees and their families a picnic at North Western Park. About 10,000 people attended this picnic.

A brief history of the Crane Company will doubtless be of interest. In the spring of 1855 Mr. R. T. Crane came to Chicago and established a brass foundry in a corner of his uncle's lumber yard. The first "heat" was taken off on the Fourth of July. The sand used was found on the premises, and the first castings were couplings for connecting lightning rods. Business prospects looking good, Mr. Crane sent for his brother, Charles S. Crane, and shortly after his arrival the firm decided to go into the making and finishing of brass goods. A foot lathe was purchased, and the manufacture of brass engine trimmings begun. A few months later a room with power was rented, and the following spring a small three-story frame building was erected and equipped for power with a 6-h.p. portable engine. The next year jobbing in wrought-iron pipe and fittings and steam warming work was taken up.

After the breaking out of the civil war the enormous demand of the government for all sorts of material created a boom; soon the brass plant had to be enlarged, and the manufacture of brass globe valves, check valves, steam and gas cocks was begun. An iron foundry was started, and the building, in a small way, of machinery and the making of a few articles in the steam fitting line was undertaken. About the same time a small butt-weld pipe mill, the first mill west of Pittsburg, was built on ground where the Crane Company still has a pipe mill. In the same year ((1864) the property where the present brass department is located, No. 10 North Jefferson Street, was purchased and the first malleable iron foundry outside of the Eastern States started. This foundry was on the second floor and is said to be the first instance of a foundry being located above the ground floor. The manufacture of both malleable and cast-iron fittings was commenced, and in connection with the fitting business the company early took up the manufacture of dies and die plates.

In 1865 the business was incorporated by Richard T. Crane, Charles S. Crane, Martin Ryerson, Eliphalet W. Blatchford, Charles N. Holden, and the name changed from R. T. Crane & Bro. to the Northwestern Manufacturing Company. This name was retained until 1872, when the title Crane

Bros. Manufacturing Company was adopted, which was changed in 1890 to Crane Company. By 1870 the business had grown so that further extensions were necessary. The land west of the property at No. 10 North Jefferson Street was purchased and a building erected thereon. Fortunately the company escaped the big fire of 1871, and the large increase that had recently been made in facilities enabled the company to take advantage of the heavy demand for goods created in the rebuilding of the city. In 1881 another pipe mill was erected on property purchased on West Twelfth Place where there were excellent railroad facilities. One lap-weld and two butt-weld furnaces were erected.

Although the Crane Company was concentrating upon the manufacture of valves and fittings, the continued growth of the business demanded extensive additions in 1891, 1899, 1900, 1902, 1903, and this year a five-story modern office building has been erected. Not only has there been an immense increase in the floor space used for manufacturing purposes, but all departments have been equipped with the latest improved machinery, much of which has been designed and built by the company.

The company has constantly added to its lines of manufacture. Some of the important classes of goods put on the market in more recent years have been stationary, marine and locomotive pop safety valves, drainage fittings, extra heavy brass and iron valves and fittings, hydraulic valves and fittings, ferro-steel flanged fittings and valves, ammonia fittings, steam traps, steam and oil separators, malleable and ferro steel companion flanges, electrically and hydraulically operated and steam actuated valves, and a complete line of flat band fittings. In addition the company is prepared to turn out complete piping equipments for power plants, and has facilities for bending and threading all sizes of pipe, and screwing, welding and rolling flanges on it. All told, the Crane Company manufactures more than 10,000 articles for use in connection with steam, water, gas or air.

NEW BOOKS.

MODERN ELECTRICAL CONSTRUCTION. By H. C. Horstmann and V. H. Tousley. Chicago: Frederick J. Drake & Co. Flexible leather; 242 pages, 4 ins. x 6½ ins.; 138 illustrations. Price, $1.50.

This is a rather skillful combination of an explanation of the Fire Underwriters' rules and an exposition of the elementary features of electrical engineering. The authors describe batteries, bells, dynamos, lightning arresters, etc., etc., and explain the application of the Underwriters' Rules to the installation of such apparatus. The book is liberally illustrated and should be extremely useful to practical workers in the electric lighting and power field.

ELECTRICAL INSTRUMENTS AND TESTING. By Norman H. Schneider. New York: Spon & Chamberlain. Cloth, 199 + xvi pages, 5 ins. x 7½ ins.; 105 illustrations. Price, $1.00.

This little book embodies a commendable effort to present in simple language the elementary features of electrical testing, and the author has succeeded so well as to disarm any unhardened critic who might find occasion to comment unkindly on the diction and methods of exposition. The statements, so far as the reviewer has analyzed them, are accurate, and the arrangement of the contents logical. After describing the usual instruments employed in testing circuits, the author explains all the ordinary tests that are needed in the general run of work. The book is excellent.

AMERICAN TELEPHONE PRACTICE. (Fourth Edition.) By Kempster B. Miller. New York: McGraw Publishing Company. Cloth, 888 + xvi pages, 6½ ins. x 10 ins.; 643 illustrations. Price, $4.00.

This edition of Mr. Miller's excellent book shows evidence of exhaustive revision and leaves very little to be desired. The old chapters have been practically rewritten, and much new material has been added, notably discussions of common battery systems, the divided multiple system, private branch exchanges, party lines, meter service, and power plants for common battery systems. The book has an enormous scope, so that criticism of any failure to cover features of minor importance might seem captious; it is to be regretted, however, that the different systems of exchange and subscribers' instruments and connections could not have been shown in complete elemental form in each case; except for this, one would need to exert oneself abnormally to find an excuse for adverse comment. The book must prove invaluable to telephone engineers and others actually interested in telephone exchange work.

GAS ENGINE DESIGN. By Dr. Charles E. Lucke. New York: D. Van Nostrand Company. Cloth; 254 + viii pages, 6 ins. x 9 ins.; 145 illustrations. Price, $3.00.

Dr. Lucke is one of the few college professors whose practical engineering abilities have developed along with their technical academic education, and as a consequence the present work is a superb one. The book is restricted to the quantitative side of gas engine design and construction, and contains an immense amount of valuable data collected from practice as it has developed during the past several years. Beginning with a discussion of power, efficiency and economy, the author briefly develops the formulas giving the relations between indicated horse-power, mean effective pressure, cylinder dimnesions, piston speed, explosions per minute and piston displacement, for two-stroke and four-stroke cycle engines; gives a standard reference (indicator) diagram based on adiabatic compression and expansion, explains fuel characteristics and the ratio of actual to ideal pressures during a cycle, and gives a great deal of practical data and many useful formulas. The next section is devoted to the forces in a gas-engine cylinder due to gas pressure and inertia. Some actual indicator cards are presented and discussed, and the relation between the reciprocating parts and kinetic forces is taken up in refreshing detail. The final section contains an elaborate discussion of engine parts (weights and dimensions). A detailed review of the work is impracticable, owing to the thoroughness with which it has been carried out; such a review could easily grow into a small volume, most of the contents of which would be commendatory. The only serious fault noticed by the reviewer is slovenly diction; the rather reckless use of the letter *C* as a symbol is greatly inconvenient to the reader, but it scarcely attains the magnitude of a defect.

PERSONAL.

MR. FRED STADELMAN has been appointed assistant manager of the New York office of The Wellman-Seaver-Morgan Company.

MR. B. H. WARREN, president of the Allis-Chalmers Company, has just returned from an extended European trip, arriving on the *Baltic*, July 20.

MR. FRANCIS RAYMOND has severed his connection with the Stanley-G. I. Electric Manufacturing Company to re-enter the field as manufacturer's agent.

MR. ROBERT C. REED has been appointed superintendent of the electrical department of the Duquesne Steel Works of the Carnegie Steel Company.

MR. W. A. STADELMAN, heretofore eastern agent of The Wellman-Seaver-Morgan Company, with headquarters in New York, has been appointed general sales agent of the company, with headquarters at Cleveland, O.

MR. M. B. BEATTIE, formerly connected with the power and mining department of the General Electric Company, has recently resigned his position there to accept one with the Chicago office of the Crocker-Wheeler Company.

MR. ARTHUR WILLIAMS, of the New York Edison Company, recently sailed for Europe for a rest of a few months. While abroad Mr. Williams will look very thoroughly into the municipal ownership situation on the other side.

MR. HARRY V. CROLL, for the past eight years with the E. P. Allis Company and its successor, the Allis-Chalmers Company, of Chicago, has resigned to accept a position with The Wellman-Seaver-Morgan Company, of Cleveland, O.

MR. A. H. WHITESIDE, who has for a considerable time been manager of the Allis-Chalmers Company's district office at Atlanta, Ga., was transferred, on July 15th, to the Philadelphia district office, where he succeeds Manager W. A. Wood, resigned.

MR. W. J. BUCKLEY, who has earned an enviable reputation as a salesman of electrical machinery in the Southwest, has been appointed manager of the Allis-Chalmers Company's district office at St. Louis. Mr. H. P. Hill, whom he succeeds, goes to the Salt Lake City district office, where he will devote his energies to the electrical branch of the company's business.

MR. M. W. THOMAS has been appointed manager of the Allis-Chalmers Company's district office at Atlanta, Ga. Mr. Thomas is widely known in the South, where he has been identified for years with electrical and machinery interests. He was until recently manager of the Westinghouse Electric & Manufacturing Company's office in New Orleans and brings to the Allis-Chalmers Company the advantage of a very large and valuable acquaintance.

MR. HAROLD U. WALLACE, son of Mr. John F. Wallace, who recently resigned the chief engineership of the Panama Canal Commission, has accepted the third vice-presidency of J. G. White & Co., New York. Mr. Wallace resigns as chief engineer of the Illinois Central Railroad to accept this position. He has been connected with that road since 1894, and since 1902 has been its chief engineer. Among important work carried

out for the Illinois Central Railroad by Mr. Wallace was the lake front improvement work at Chicago. This work included the depression and reconstruction of twenty miles of main lines and yard tracks. In securing the services of so distinguished an engineer as Mr. Wallace, the White Company is simply following out its uniform policy. It has of late secured the services of several eminent engineers and it has made its recent selections largely from the steam railroad field.

MR. W. M. PROBASCO has resigned as assistant to the president of the McGraw Publishing Company to accept the office of vice-president of the Search Light Publishing Company. The latter company owns a file of about 2,500,000 clippings, articles and pictures on all subjects, compiled from newspapers, magazines, engineering journals, books and reports of scientific societies, and has a carefully organized force by which this information is classified and kept up to date for the use of publishers and others who require prompt and up-to-date information on any subject. In addition, the company publishes a weekly paper, called *The Search Light,* which is a record of the most important events of the previous week and which covers some sixty separate departments. As a nucleus for this paper the company purchased *The Great Round World* and *The Week's Progress,* publications somewhat on the line of its own, but has improved on their plans and especially in the completeness with which the information is compiled and indexed. Mr. Probasco is well known in electrical circles and his many friends will wish him success in this new departure.

TRADE PUBLICATIONS.

SUNBEAM REFLECTOR LAMPS. Sunbeam Incandescent Lamp Company, Chicago, Ill.—This is Bulletin No. 11, containing an illustrated description of the Sunbeam reflector lamp, which is made in sizes ranging from 6-c.p. to 36-c.p.

A TALK ON ARC LAMPS. The C. J. Toerring Company, Philadelphia, Pa.—Bulletin No. 6, containing an interesting discussion on the well-known Toerring enclosed arc lamp. The bulletin is well illustrated and the argument convincing.

PREPAYMENT WATTMETERS. Fort Wayne Electric Works, Fort Wayne, Ind.—Publication No. 5008 and Bulletin No. 1066 devoted to the prepayment form of alternating current wattmeters which was described in the June number of this journal.

SMALL DIRECT-CONNECTED DYNAMOS. Crocker-Wheeler Company, Ampere, N. J.—Bulletin No. 55, containing a brief description of a line of dynamos ranging from 1½ to 28 kilowatts and designed for direct connection and consequently slow speed.

DOSSERT SOLDERLESS CONNECTORS. Dossert & Company, New York.—This is catalogue No. 1, containing a description of the a brief explanation of the prinicple on which Dossert wire and cable connectors and taps, with these devices are based.

RENOLD ROLLER CHAIN. The Link-Belt Engineering Company, Philadelphia, Pa.—This is booklet No. 54, containing an illustrated description of a roller chain provided with special bushings and anti-friction rollers and intended for operation on ordinary sprockets.

EVERBEST MAGAZINE. Ewing-Merkle Electric Company, St. Louis, Mo.—This is the July number of this clever little publication and contains, in addition to interesting non-partisan reading matter, advertisements of the principal specialties handled by the publishers.

SMALL SPRINGS. The Wallace Barnes Company, Bristol, Conn.—This is catalogue No. 4, devoted to the line of small steel springs manufactured by this company. The line includes springs of every conceivable type and shape. The catalogue is superbly executed and profusely illustrated.

TRANSFORMERS. Stanley-G. I. Electric Manufacturing Company, Pittsfield, Mass.—Bulletin No. 249, devoted to "Type Z" transformers, which are of the shell type and built in sizes ranging from ½ to 30 kilowatts. The bulletin is profusely illustrated and the transformer is thoroughly described.

ELECTRICAL SPECIALTIES. The Yost Electric Manufacturing Company, Toledo, O.—A handsomely executed catalogue, slightly smaller than standard size and containing well-illustrated descriptions of Yost specialties, which include the well-known lamp sockets, receptacles, rosettes, lamp cord adjusters, shades, etc.

"A B C" FANS AND BLOWERS. American Blower Company, Detroit, Mich.—Catalogue No. 180 and folder No. 66. The former is devoted to exhaust fans of the paddle wheel type and the latter to disc or propeller-type ventilating fans driven by electric motors. Both publications are executed in the artistic style customarily employed by the company.

ELECTRIC SIGNS. A. C. & M. L. Felkin Company, Boston, Mass.—This is a catalogue of electric signs containing an illustrative description of the Imperial electric signs made by this company. These signs are of the general class in which transparent letters are employed, this being illuminated by incandescent lamps on the inside of the sign structure.

DE LAVAL WORKS AND PRODUCTS. De Laval Steam Turbine Company, New York and Trenton, N. J.—Bulletin No. 10, containing a profusely illustrated description of the De Laval factory, in which the well-known turbines and pumps are built, together with illustrations and descriptions of some of the turbine parts, processes of manufacture, etc.

KOERTING GAS ENGINES. De LaVergne Machine Company, New York.—This is the 1905 catalogue devoted to the Koerting two-stroke cycle gas engine and also containing illustrations of the Koerting four-stroke cycle engine and the Hornsby-Akroyd oil engine built by the De La-Vergne Company. The catalogue is liberally illustrated and handsomely executed.

DIRECT-CURRENT MOTORS AND DYNAMOS. Stanley-G. I. Electric Manufacturing Company, Pittsfield, Mass.—Bulletin No. 145, containing a detailed description of the "Type L" direct-current motors and dynamos built by this company. This line of machines ranges from ¼ to 15 horse-power in motor ratings and corresponding generator ratings. The description is illustrated and the bulletin is well executed.

BUSINESS NEWS.

WESTINGHOUSE ELECTRIC & MANUFACTURING COMPANY has removed its Los Angeles office from the Trust Building to No. 527 South Main Street.

AMERICAN ELECTRICAL HEATER COMPANY, Detroit, Mich., has established an eastern branch at 35 Dey Street, New York, in charge of Mr. B. H. Scranton. A warehouse will be maintained here, in which a full stock of standard goods will be carried.

CROCKER-WHEELER COMPANY, Ampere, N. J., has just received an order through its New York office for two engine-type generators of 105 volts and 10,000 amperes for use in the electrolytic treatment of ores. These machines will have 22 field magnet poles and will run at 100 r.p.m.

CHARLES R. UNDERHILL, New York, announces that he is now in a position to supply the trade with all kinds of small electro-magnets, induction coils, spark coils, and coil windings of every description, and in any quantity, in addition to the large electro-magnets and solenoids which have heretofore been his specialty.

CHANDLER & TAYLOR COMPANY, Indianapolis, Ind., reports that it was the successful bidder for a high-speed, self-oiling, direct-connected engine to be installed in the new power plant of Mandel Brothers, Chicago. The contract was secured in keen competition with other representative manufacturers, and the Chandler & Taylor Company naturally feels much gratification upon receiving the award.

A. L. IDE & SONS, Springfield, Ill., report among recent sales of Ideal engines the following: Wilkes-Barre Gas & Electricity Company, two direct-connected units: Hackensack Water Company, one direct-connected unit; Compania Exportadoes Coahuilente, one belted engine; City of New York, for Williamsburg Bridge, three direct-connected, cross-compound units; Anglo-Chilean Nitrate & Railway Company, one belted engine; Edison Electric Illuminating Company, three special engines to operate blowers.

THE NEW JERSEY ASBESTOS COMPANY, of Camden, N. J., reports increased activity in all departments, and is particularly gratified at the reception accorded the new high pressure packing. In the South the company's business has increased to such an extent as to render it necessary to open a branch office at Birmingham, Ala. Mr. James J. O'Rourke, who was for a long time connected with the Southern Railway Company, and who is well and favorably known to both railway and supply men, as well as to the trade in general, has been appointed manager of the Birmingham office.

JAMES McCREA & CO., Chicago, manufacturers of the "Climax" steam joint clamp for repairing leaks where pipes are screwed into fittings, and the "Emergency" pipe clamp for repairing splits and rust-holes on pipes, have just applied for a patent for a novel device in the way of a clamp for stopping leaks between pipe flanges. Every engineer has experienced difficulty with leaks of this kind occurring when it was impossible to shut down to renew packings, or when the flanges were in some inaccessible place where they could not be repacked without great expense and trouble.

THE ABNER DOBLE COMPANY, San Francisco, has secured the contract for the machinery to be installed in an addition to the hydro-electric plant of the Cramer Electric Company, at Hailey, Idaho. This contract covers the entire outfit of hydraulic and electrical machinery and apparatus and includes a 400-kw. alternator direct-driven by an 800 horse-power set of water-wheels, with exciter and governor; a three-panel marble switchboard; two 25-light arc transformers and 50 arc lamps, with regulators and other accessories; 14 transformers and supplies for the distribution system.

G. M. GEST, of New York and Cincinnati, has been awarded a contract for the construction of a complete underground conduit system at Washington, D. C., for the Western Union Telegraph Company. The conduits will be constructed of specially made steel pipe, instead of clay, and will connect all of the Western Union Telegraph Company's offices as well as the department buildings in and around Washington. Mr. Gest has also been awarded a large contract in New Orleans for the extension of the subway system of the Cumberland Telephone & Telegraph Company. This is an extension to the original system which he installed several years ago.

THE STROMBERG-CARLSON TELEPHONE MANUFACTURING COMPANY., Rochester, N. Y., reports having closed a contract with the Kinlock Telephone Company, St. Louis, Mo., for a new central energy lamp line multiple switchboard of 17,000 lines capacity for the main exchange. The contract calls for an "A" board of thirty-seven sections, a "B" board of ten sections, three monitor sections of two operators' positions each, one observation desk of four positions, one combination manager's and assistant manager's desk, one combination chief and assistant chief operator's desk and one two-position wire chief's desk. The company also reports having closed a contract with the North State Telephone Company, High Point, N. C., for a 1200 line capacity, generator-call, visual signal switchboard, and one with the Anderson Telephone Company, Anderson, S. C., for an 1800-capacity lamp line signal multiple switchboard.

ALLIS CHALMERS COMPANY has begun the great extensions to its already large works at West Allis, Milwaukee. The company has awarded contracts for the structural steel, erected in place, for three of the new buildings, requiring approximately 6800 tons of steel; and for the structural steel, erected in place, for the foundry and pattern storage buildings and erecting shops, comprising approximately 4000 tons of steel. The company expects to occupy its new works on or before next March. Some idea of the size of the works when extended will be afforded by the fact that the company's present floor space at West Allis, Milwaukee, has a total area of 652,000 square feet, and the new extensions upon which work is now in progress will add 861,000 square feet, more than doubling the present floor space and making the total at the West Allis Works 1,513,000 square feet of floor space. The plant will be capable of affording employment for 11,000 persons.

Exhibits at the Electrical Contractors' Convention.

THE TIPLESS LAMP COMPANY, New York, sent Mr. R. S. Carrick to represent them.

THE HART & HEGEMAN MANUFACTURING CO., Hartford, Conn., was represented by President A. H. Pease, who was a visitor at the convention and exhibition.

THE GOULD STORAGE BATTERY COMPANY, New York, was represented at the convention by Mr. Wm. S. Gould.

MEITZ & WEISS COMPANY, New York, had a large display of their oil engines in charge of F. E. Davis, New England agent.

JOHNSON & MORTON, Utica, N. Y.—W. H. Morton, secretary of the N. E. C. A., represented his company at the convention.

THE TRAY PLATE BATTERY COMPANY, Binghamton, N. Y., had Mr. H. B. Oakman as their representative at the convention.

ECONOMICAL ELECTRIC LAMP COMPANY, New York, had n exhibit of their turn-down lamp. Mr. W. K. Abely was in charge of the exhibit, assisted by C. F. Murphy.

COUCH & SEELEY COMPANY, Boston, had a most attractive exhibit of their line of telephones. Mr. E. B. Seeley, manager, and F. C. Redfield were in charge.

THE RENIM SPECIALTY COMPANY, Boston, showed a full line of samples of its switch and outlet boxes, cut-out cabinets and trims. Miner Robinson was in charge.

MANHATTAN ELECTRICAL SUPPLY COMPANY, New York, had a very tasteful booth in which to entertain its friends. Mr. J. W. McDowell was in charge.

in carbon that is used for electrical purposes. The exhibit was in charge of J. C. Irvine and A. C. Henry.

THE WORCESTER ELECTRIC MANUFACTURING COMPANY, Worcester, Mass., had an attractive booth showing samples of its line of switches. Mr. James McGrady was busy explaining the good points.

COOLEY GENERAL DEVELOPMENT COMPANY, Jamaica Plain, Mass., had on exhibition a number of the Cooley engines of different sizes. J. F. Cooley, D. Wood and Andrew Rhoades represented the company.

THE SIMPLEX ELECTRICAL HEATING COMPANY, Cambridgeport, Mass., made a fine display of their electrical cooking and heating apparatus. C. W. Richards and A. W. Doe were in charge of the exhibit.

THE AMERICAN ELECTRIC SIGN COMPANY, Boston, had on exhibition samples of its time switches, advertising mirrograph, flashers and signs of every description. J. L. Russell, C. M. Borden and C. I. Wetmore were present.

GENERAL VIEW OF THE MAIN EXHIBITION HALL, NATIONAL ASSOCIATION OF ELECTRICAL CONTRACTORS.

THE JOHNS-PRATT COMPANY, Hartford, Conn.—Mr. E. B. Hatch and Joseph Sachs represented their company at the convention.

MUNDER ELECTRIC COMPANY, Springfield, Mass.—Mr. Charles Munder attended the convention in the interest of his company.

DOSSERT & CO., New York, made an attraction of their solderless joints. M. R. Jarvis and R. A. Bristol represented the company.

HART MANUFACTURING COMPANY, Hartford, Conn., was represented by Mr. H. A. Hart and F. B. Smith, New England representatives.

DIEHL MANUFACTURING COMPANY, Elizabethport, N. J.—Mr. B. C. Kenyon, president, represented his company at the convention.

HOLTZLER-CABOT COMPANY, Boston, made a large and very attractive display of their several lines. Mr. E. W. Schildknecht had charge of the exhibit.

H. T. PAISTE COMPANY, Philadelphia, had an attractive display of their line of specialties in charge of E. A. Jenkins, C. K. Hills and Geo. MacElwee.

THE ALPHADUCT MANUFACTURING COMPANY, New York, had an attractive space filled with samples of alphaduct flexible conduit, in charge of Russell Dart, Jr.

HARVEY-HUBBELL, INC., Bridgeport, Conn.—H. W. Bliven, sales manager, was in charge of their exhibit. The newest device shown was their porcelain wireless cluster.

D. & W. FUSE COMPANY, Providence, R. I., had an attractive show board filled with samples of its line of fuses. W. S. Sisson was a very busy representative of this company.

ELECTRO-DYNAMIC COMPANY, Bayonne, N. J., had an attractive booth with samples of their interpole motors. F. G. Bell, F. S. Mitchell and Geo. B. Warren represented the company.

THE DALE COMPANY, New York, occupied a very large space, filled with samples of the Dale line of fixtures. John Dale, O. J. Bryan and H. S. Rainford were present during the week.

NATIONAL CARBON COMPANY, Cleveland, O., had a display showing samples of everything

THE BENJAMIN ELECTRIC MFG. COMPANY, New York and Chicago, had show boards displaying the Benjamin wireless clusters, arc burst, daylight clusters and car clusters. Basil G. Kodjbanoff was in charge of the exhibit.

PASS & SEYMOUR, Syracuse, N. Y., were represented by J. W. Brooks, A. M. Little and W. B. Hall. A full line of P. & S. specialties was on exhibition, as well as the new brass shell sockets and receptacles made by the firm.

SPRAGUE ELECTRIC COMPANY, New York, was ably represented at the convention by Alec Henderson, master of transportation of the N. E. C. A., who arrived Tuesday evening in charge of a large party of delegates from New York.

G. M. GEST, New York and Cincinnati, was represented at the convention by W. T. Jackson, Western representative, who showed a large variety of photographs of the different kinds of conduit work done by Mr. Gest all over the world.

THE OSBURN FLEXIBLE CONDUIT COMPANY, New York, had an attractive display of

flexiduct in connection with the exhi'it of the Pettingell & Andrews Co., their New England agents. Mr. C. E. Corrigan represented his company.

J. L. GLEASON, Jamaica Plain, Mass., had a very handsome exhibit of his line of moulding boxes. He recently brought out a number of new specialties, samples of which were shown and explained. J. L. Gleason and R. Eberhardt were in attendance.

THE CHASE-SHAWMUT COMPANY, Newburyport, Mass., displayed samples of the standard fuses, Shawmut conduit outlet bushings, Shawmut rapid conduit and moulding hangers. Harry P. Moore, J. F. S. Nichols, Jr., J. J. Miley and Frank D. Masterson were in attendance.

CHARLES A. COTTON, Boston, New England agent for the Triumph Electric Company, Century Electric Manufacturing Company and the Warren Electric Company, had a large exhibit of the motors built by these companies. Charles A. Cotton and A. J. Ruel were in charge of the exhibit.

S. H. COUCH & CO., Boston, Mass., had an exhibit of their line of telephones, shown on revolving pedestals. One of their newest was the Couch automatic vestibule 'phone for apartment houses. Wm. Couch and C. E. Monroe explained the merits of their line and distributed souvenir match safes.

THE HOLOPHANE COMPANY, New York, had some very interesting samples of the Holophane products. The newest shade shown was the new Pagoda ball, wide-angle reflector, together with some handsome cut-glass effects. The exhibit was in charge of I. W. Farquharson and H. C. Jones, Boston representative.

JOHN A. ROEBLING'S SONS COMPANY, Trenton, N. J., occupied a very handsome booth, which was considered by some the coolest spot in the show. Mr. H. L. Shippey, treasurer and manager of the New York office; Albert Mann, New England agent; Frank W. Harrington and S. B. Van Norturck were in attendance.

EXHIBITS OF THE AMERICAN CIRCULAR LOOM COMPANY AND PERKINS ELECTRIC SWITCH MANUFACTURING COMPANY.

H. W. JOHNS-MANVILLE COMPANY, New York, had an attractive display of Sacks noark fuses, standard fuses; in fact, fuses, fuse boxes and fuse blocks for every possible service. J. W. Perry, manager of the electrical department, New York; A. D. Newton, manager electrical department, Boston; E. L. Cameron and W. R. Walsh were in attendance.

THE O. C. WHITE COMPANY, Worcester, Mass., had a handsome exhibit of shop wall fixtures, etc. The company showed fixtures designed for every practical requirement of applied illumination. Two specialties which it has brought out this season were a portable lamp fixture and a new strap clamp desk fixture. O. C. White, Jr., was in charge of the exhibit.

MARSHALL ELECTRIC MFG. COMPANY, Boston, Mass., had a very attractive booth decorated in red and white. Samples were shown of the company's complete line of sockets, cutouts and switches. Norman Marshall was attending the convention. E. G. Eastman had charge of the exhibit. A combination key ring and screwdriver was given out as souvenirs.

PASS & SEYMOUR AND GENERAL ELECTRIC COMPANY EXHIBITS.

R. M. CORNWELL COMPANY, Syracuse, N. Y.—The booth occupied by this company was most attractively decorated. The company had on exhibition samples of the Cornwell universal switch boxes, wonder dynamos and motors for experimental purposes, and the wonder gasoline engine in several sizes. Mr. R. M. Cornwell and F. S. Baldwin had charge of the exhibit.

C. S. KNOWLES COMPANY, Boston, Mass., had a display of their enamel duct conduit, high-tension porcelain glass insulators and B. & D. specialties. They also had on exhibition a 300,000-volt transformer for testing insulators. The following gentlemen were in attendance: George A. Ober, Duncan Kennedy, A. D. Richmond, H. M. Saben, A. J. Sanford, Jr., and W. O. Turner.

BOSSERT ELECTRIC COMPANY, Utica, N. Y.—The space occupied by this company was most attractively furnished and samples of outlet boxes, outlet bushings, knife switches, and a line of novel and up-to-date panel boards were displayed. F. B. Smith, New England sales agent, and F. T. Foxenberger were busy explaining the merits of the Bossert line to visiting delegates.

THE AMERICAN ELECTRIC NOVELTY & MANUFACTURING COMPANY, New York.—This exhibit was in charge of Mr. F. J. Alvin, general manager. Wm. G. Mills and S. S. Shephard were also in attendance. Theirs was a very elaborate booth, filled with samples of the famous ever-ready battery, minature and decorative lamps, Noscru push buttons, keyless clocks, portable lamps, etc.

W. S. HILL ELECTRIC COMPANY, New Bedford, Mass., had on exhibition sample boards of its line of switches together with a board showing I. T. E. circuit breakers manufactured by the Cutter Electrical Manufacturing Company, for whom the Hill Company is New England agents. W. C. Jessup, sales engineer, and F. A. Knowles, manager of the Boston office, represented the company.

SAFETY-AMORITE CONDUIT COMPANY and the CONDIT ELECTRICAL MANUFACTURING COMPANY had a very attractive booth. S. B. Condit, Jr., R. G. Garland and F. Hodkinson represented the Safety Company, while Mr. S. B. Condit, Jr., P. Fisher and F. W. Mason looked after the interests of the Condit Electrical Manufacturing Company. Very handsome and useful desk clocks were distributed as souvenirs.

PETTINGELL-ANDREWS COMPANY, Boston, occupied one of the largest booths in the building, and had on exhibition samples of practically everything in the electrical supply line. The following gentlemen were in attendance, representing the company: C. B. Price, general manager and treasurer; F. S. Price, secretary; W. J. Keenan, sales manager. Wm. A. Peterson, R. W. Vose, H. H. Van Staagen and F. W. Cramphorn.

THE TRUMBULL ELECTRIC MANUFACTURING COMPANY, Plainville, Conn., had what was perhaps the most attractive show board in the entire exhibition. It was a quartered oak cabinet finish board, 15 feet long by 7 feet high, upon which were displayed samples of the entire line

of switches, cut-outs, panel boards, etc., manufactured by this company. Mr. J. H. Trumbull, president; F. Trumbull and Geo. W. Edge were in constant attendance.

EASTERN CARBON COMPANY, Jersey City, N. J., had its booth tastefully decorated with red and yellow bunting; the prevailing colors in the label of their dry cell. Samples of gas ignition cells, telephone cells, new battery connectors, carbon specialties, eastern flash lights in all sizes and shapes, and a new combination carbon brush composed of wire gauge and carbon were on exhibition. The following gentlemen were in attendance: George W. Mills, William Mills, O. L. Turgeon.

EXHIBITS OF THE MARSHALL ELECTRIC MANUFACTURING COMPANY AND R. M. CORNWELL COMPANY.

THE AMERICAN CIRCULAR LOOM COMPANY, Chelsea, Mass., following its usual liberal policy, had one of the largest exhibits in the building. Across each end of the space were two large circular loom trucks loaded with circular loom. The centre of the space was filled with weathered oak furniture, palms, flowers, etc., very artistically arranged. The following gentlemen were in attendance: A. J. Clark, H. P. Kirkland, Oscar Hoppe, R. B. Corey, T. H. Bibber, H. C. Adams, Jr., and M. W. King.

THE ELECTRIC GAS LIGHTING COMPANY, Boston, had a remarkably fine showing of interior telephones and switches. The company was represented by H. C. Thomson, general manager; W. F. Abely, Mr. Boardman, Mr. Youny, Mr. Sherman, Mr. Howes, Mr. Norris, Mr. Lee, besides Mr. Haines, manager of the Chicago branch, and Mr. Bongard from the Toronto branch. Much favorable comment was made on its new metallic circuit, automatic intercommunicating telephone. The company claims this is the most important departure in the history of interior telephone manufacture, inasmuch as it gives a complete and separate metallic circuit to every talking pair; not only does the operator at will select the metallic circuit of the desired correspondent, but when a conversation is in progress interruption by outsiders is entirely impossible. The "Rotokoll" switchboard was also shown.

BRYANT ELECTRIC COMPANY, and PERKINS ELECTRIC SWITCH MFG. COMPANY. —This is the first time these companies have ever made an exhibit of their line. Much credit is due to Mr. E. R. Grier, sales manager, for the very effective display made. This company manufacture over 2,000 different articles and are the largest manufacturers of what they term "electrical hardware" in the world. Their main exhibit was a tent shape arrangement of show boards. On one side was shown the Perkins Electric Switch Mfg. Company's lines of switches, from 15 amperes to 400 amperes. They build more than 400 sizes between. On the other side of the board the Bryant Electrical Company's sockets and receptacles were shown. At one end there was a very artistic display of cartridge fuses and fuse blocks. This is an entirely new line for the Bryant Electric Company. On separate boards were shown different finishes for sockets and switches. The following gentlemen were present: W. C. Bryant, manager and treasurer; E. R. Grier, sales manager; E. K. Patton, Western manager; G. W. Goodrich, general superintendent; B. C. Gilpin and Frank B. Burton.

THE WESTINGHOUSE EXHIBIT.

THE GENERAL ELECTRIC COMPANY had one of the largest spaces in the center of the main floor, covering about 1,300 square feet. The principal feature of this exhibit, and probably the newest thing in the entire Exhibition, was the new G. E. 2½ watt incandescent lamp. The company's exhibit was brilliantly illuminated with these units. This is the first exhibition to the general public where this carbon filament has been shown. The new metallized carbon filament lamp is made in three sizes, Nos. 3, 4 and 5, the watt consumption being 125, 187½ and 250 watts per lamp, respectively. These lamps are used with a special line of Holophane Pagoda reflectors which are made in two forms, one known as the "Form D," which distributes the light in a downward direction, and the other known as the "Form C," which concentrates the candle-power in a downward direction. The company also exhibited a mercury arc rectifier operated on 220 volt, single-phase, which was converted to 110 volts, direct current, the load being a circuit of the new incandescent lamps. This rectifier had a capacity of 30 amperes and was in constant operation. A collection of small motors of various types was shown. This included alternating and direct-current motors. One of the company's new automobile motors was also exhibited, as well as a miscellaneous collection of the company's standard electric motor fans. A new G. E. electric flat-iron also made its appearance here for the first time and naturally attracted a great deal of attention from the public. The company's moving picture machines were constantly surrounded during the exhibition. In attendance at the exhibit were Mr. C. B. Davis, Boston manager; Mr. J. P. Felton, supply manager Boston office; Mr. O. F. Brastow, L. E. Smith and J. A. Wilson, Boston; Mr. E. M. Kinney, Schenectady, N. Y.; Mr. W M. Wright, New York, and Mr. F. H. Gale, advertising manager. Other callers during the week were Mr. T. Beran, New York supply manager, and Mr. D. R. Bullen, Schenectady.

THE WESTINGHOUSE ELECTRIC & MANUFACTURING COMPANY occupied an entire platform at the west end of the main hall. Over the center of the exhibit was a large, high-potential electric sign bearing the word "Westinghouse" in porcelain letters on a dark background. The letters were backed with tin foil and alternating discharges at 30,000 volts between the backs produced striking effects. Various types of Sawyer-Man lamps were displayed in a glass case on the platform. Along the front of the platform were vertical standards bearing a nice display of Nernst lamps. A 42-in. Stafford fine yarn cotton loom was shown in full operation, being gear driven by a ½ h.p. three-phase, 200-volt, 25-cycle induction motor with automatic stopping devices actuated by the breaking of the thread in the weaving process or other mishaps in the loom proper. The purpose of showing this outfit was to demonstrate the feasability of driving such a loom without intermediate clutch or other starting device. The cotton was woven by an expert weaver and portions of it distributed as souvenirs. Souvenir postal cards illustrating historic points of Boston were also distributed. A line of central-station and portable testing instruments was on exhiibtion, as well as Cooper Hewitt mercury vapor lamps, fuses, arc lamps, etc. A biograph exhibition comprising a trip to the Westinghouse shops at East Pittsburg was given nightly. The company was represented by the following attaches of the main and district offices of the company: R. L. Warner, New England manager; C. B. Humphrey, manager detail sales; G. B. Griffin, assistant manager detail sales; D. E. Manson, manager Boston office; H. B. Whipple, general lamp agent; J. William Smith, cashier Sawyer-Man Company; Messrs. Watts, Merrill, Bates, Osborn, Gibbs, Bond, Chase, Wahn, Abbott, Walton and Ewing of the Boston office of the Westinghouse Electric & Manufacturing Company; D. E. Clark, manager The Westinghouse Machine Company; Mr. Holbrook, manager Boston office Nernst Lamp Company, and J. C. McQuistion, superintendent of the Westinghouse Companies Publishing Department, who had charge of the Westinghouse exhibit.

CENTRAL STATION NEWS

Readers are cordially invited to contribute to this department items of news relating to plants in their vicinity.

ALABAMA.

DOTHAN.—It is reported that it is proposed to improve the water works and electric light plant, at a cost of $20,000.

ENSLEY.—The Street and Light Committee of Council is reported to have agreed to recommend to the Mayor and Board of Aldermen the construction of an electric light plant.

MONTGOMERY.—The Montgomery Light & Water Power Company has just placed an order for additional machinery for its large plant at Tallassee, which will involve an expenditure of nearly $30,000.

JACKSON.—The lighting plant at this place, which was only completed December 15, 1904, already requires extension. It is proposed to add an overshot water-wheel. Geo. P. Brockman is electrical engineer and superintendent.

TROY.—Messrs. Chas. Henderson, H. D. Boyd and others, together with the owners of the Elba Electric Power Company, have organized the Pea River Power Company, paid up capital $50,000, authorized $200,000. They are arranging for the erection of a power house, etc. Their plans include an electric plant and railway service from Troy to Elba and perhaps on the Gulf.

ALASKA.

FAIRBANK.—The Tanana Electric Co. is reported to have been incorporated at Olympia, Wash., by Abe Spring, of Fairbank, and J. A. Haney, of Seattle, Wash., with a capital of $250,000, to establish a lighting and steam plant at Cleary City, Alaska, which is about 25 miles from Fairbank.

ARKANSAS.

IMBODEN.—A $25,000 electric lighting plant and water works is being put in at this city.

LITTLE ROCK.—The Columbia Light & Power Company filed a notice of dissolution of that corporation and surrendered its charter.

TEXARKANA.—The Texarkana Gas & Electric Light Co. has changed its name to the Texarkana Gas & Electric Co. and reduced its capital stock from $200,000 to $100,000.

CALIFORNIA.

SAN FRANCISCO.—The Sierra Nevada Water & Power Company has been incorporated, with a capital of $5,000,000, by G. B. Crittenden, W. L. Stowell, R. M. Kreiser, and others.

LOS ANGELES.—The City Council has been asked by the Municipal League to consider the matter of a municipal lighting plant. The present cost of lighting is about $133,000 annually.

VENTURA.—The proposed electric light plant for Ventura will cost $25,000, and the water works $100,000. It is uncertain when the contracts will be let, as the matter is delayed by ligitation.

LOYALTON.—The Loyalton Electric Light Company is extending its service to Beckwith, 17 miles from here, across the Sierra Valley. The town of Beckwith will be lighted by electricity in the near future.

SAN FRANCISCO.—The Board of Supervisors has passed a resolution awarding to the San Francisco Gas & Electric Company the contract for supplying the city with gas, electric light and power during the year, for $320,000.

OAKLAND.—The bid of the Oakland Gas, Light and Heat Company for lighting the city for the next fiscal year, has been accepted and the contract awarded it on a schedule that will furnish light all night every night in the year.

LOS ANGELES.—A new city ordinance has gone into effect, providing that electric energy supplied by the lighting company shall not vary more than 3 per cent. from the standard; also for tests of electric meters to be made by the city electrician.

LOS ANGELES.—The City Council has passed a new ordinance under which corporations will be obliged to submit a complete financial statement annually to the city after Jan. 1, 1906. The Council is empowered to fix a price for the service provided.

SAN FRANCISCO.—It is understood that the Merchants' Mutual Light & Power Company, of Santa Barbara, has placed provisional orders for a McEwen engine with Henshaw, Bulkley & Co., and for 250-kw., 3-phase belted generators with the Bullock Electric Company.

LOS ANGELES.—Various interested companies have been holding meetings for the purpose of devising plans whereby telegraph, telephone, electric lighting and trolley poles shall be removed throughout the city and consolidated systems erected in their place down alleys and back streets.

SAN FRANCISCO.—The Shasta Power Company will have a stockholders' meeting, Aug. 26th, to act upon a proposition to create a bonded indebtedness of $100,000 for the purpose of raising money to complete the construction and equipment of its hydro-electric transmission plant on Bear Creek, Shasta County. Work is now in progress.

ANAHEIM.—The City Trustees of Anaheim are considering the advisability of leasing the city electric light plant to the Edison Electric Company. This company claims that it can operate the plant cheaper than the city. It offers to pay the city 12 per cent. of the gross receipts of the lighting service, with an agreement to give the city the right to terminate the contract, in a year.

SAN FRANCISCO.—The Reno Power, Light & Water Co.'s plant at Reno, Nev., was shut down for ten days while the armature of the main generator was being rewound. The company's circuits were temporarily supplied from the Truckee River General Electric Company's plant at Floriston. The burn-out was caused by a cat, which climbed a pole on the high-tension line in Reno and produced a short circuit.

LOS ANGELES.—Broadway, in this city, which is over a mile long, is one of the best lighted thoroughfares in the world. Electroliers stand on either side of the street, having been created at an expense of about $15,000 by abutting property owners. These poles display 1600 ornamental incandescent lights, effectively softened by milk-white globes. This system, recently installed, is lighted by the municipality at a cost approximating $900.

CONNECTICUT.

FARMINGTON.—The Farmington River Power Company has elected directors as follows: Austin C. Dunham, James L. Howard, Atwood Collins, Henry Roberts, E. C. Terry, John S. Hunter, W. T. Bacon and H. C. Judd.

SOUTH NORWALK.—The Board of Electrical Commissioners has awarded contracts for an enlargement of the city electrical station. The proposal of the Diesel Engine Company for an engine was accepted. The contract for electrical equipment was awarded to the Fort Wayne Electric Works.

YALESVILLE.—At a borough meeting in Wallingford, $4,500 was appropriated to buy the Hotchkiss Bros.' property and rights. This purchase takes in one of the finest water privileges in the county, and will grant to the electric plant at Wallingford all the power necessary to extend it to Yalesville.

FLORIDA.

JACKSONVILLE.—Bids will be received until Aug. 4 by the Board of Trustees of the Water Works and Improvement Bonds, for furnishing f. o. b. cars Jacksonville, a motor generator set of about 300-kw. capacity, the generator to be a 550-volt, direct-current, compound-wound machine, driven by a direct-connected, three-phase, 60-cycle, 2,300-volt, synchronous motor, large enough to drive the direct-current generator to its rated capacity, machine to be arranged so as to be reversed; and an alternate bid for the same generator driven by a three-phase, 60-cycle, 2,300-volt induction motor, direct connected, of sufficient size to drive the generator to its rated capacity, the speed of the machine not to exceed 750 revolutions per minute, the machine to be mounted on a substantial cast iron base and to have large self-oiling bearings. Field rheostat for the generator and starting device for the alternator to be furnished, a full specification, giving dimensions, together with blue print or photograph to accompany the bid, and state time in which delivery can be made. R. N. Ellis, Supt.

GEORGIA.

CALHOUN.—Geo. C. Chambers, of Calhoun, will construct an electric light plant to cost from $3,500 to $4,000, and operate it with water power.

FT. GAINES.—The City Council is reported to have granted the Interstate Water Works & Construction Co., of Washington, D. C., a 50-year franchise for the construction of water works and an electric light plant.

COVINGTON.—The town of Covington has awarded a contract to W. R. Jennison, of Atlanta, for installing the new machinery for the electric lighting plant which is to be rebuilt, having been demolished by a boiler explosion.

IDAHO.

HAILEY.—The Abner Doble Company has recently secured the contract for the machinery to be installed in an addition to the hydro-electric plant of the Cramer Electric Company, successor to the Idaho Electric Supply Company, at Hailey, Idaho. This contract covers the entire water power and electrical apparatus and includes a 400-kw. alternator directly driven by an 800-h.p. set of water-wheels, exciter and governor; three-panel marble switchboard, two 25-light arc transformers and 50 arc lamps with regulators, switchboards and other accessories; 14 transformers and other supplies for the distribution system.

ILLINOIS.

OTTAWA.—The Ottawa Power Company has been formed with a capital of $5,000. James A. Seddon, Robert Gaylord and others are the incorporators.

BLOOMINGTON.—The Consumers' Light & Heat Company has been incorporated with a capital stock of $100,000. The incorporators are George M. Mattis, S. A. Power and Charles Zilly.

CHICAGO.—Plans have been filed by the Commonwealth Electric Co. for a 2-story power house to be constructed at 22d and Fisk Sts., to cost $50,000; also for a 1 and 2-story brick power house, to cost $35,000.

GRANITE CITY.—This city is in need of a good up-to-date electrical plant for street and commercial lighting. The place has a population of about 8,000, and is growing rapidly. Mr. Alvin Morefield can give information to any one interested.

QUINCY.—The Quincy Gas & Electric Company has changed its name to Quincy Gas, Electric & Heating Company. The number of directors has been increased from five to seven, and the capital stock increased from $600,000 to $2,000,000.

CHICAGO.—The Chicago & Suburban Water & Light Co. has accepted the offer suggested by Mayor Dunne that the city purchase its plant in Austin for $250,000, and an ordinance for the purchase of the system at this price has been introduced in the council.

LA GRANGE.—The LaGrange Service Company is building a large power house at Maywood. The La Grange light and water plant will also be improved, and Sargent & Lundy, of Chi-

cago, will prepare plans for a model power house. The pumps will be operated by electric power. An extra 150 horse-power boiler and engine will be installed to be used in case of accident to the Maywood plant.

INDIANA.

POSEYVILLE.—The Poseyville Electric Light & Water Company is reported incorporated, with a capital of $10,000.

EVANSVILLE.—The Evansville Gas & Electric Light Company, Evansville, Ind., is planning to erect a plant to supply power to various traction lines.

TELL CITY.—It is reported that bids will be received by Frank Hinkle, City Clerk, for new machinery to be installed at the electric light plant.

LOGANSPORT.—The City Council has passed an ordinance governing the stringing of wires in the city, providing for inspection and the licensing of all electrical workers.

KOKOMO.—The Kokomo Gas & Light Company has incorporated with a capital stock of $100,000. Alexander Linderman, K. L. Ames, L. S. Owsley and B. S. Wales are directors.

PERU.—Wm. O'Hara, City Clerk, writes this city has in contemplation the reconstruction of its electric light plant, and would like to have some one complete the project, both financially and mechanically.

CRAWFORDSVILLE. — The Crawfordsville Water & Light Company is stated to have secured a new franchise, and will at once make extensive improvements and purchase new machinery.

WATERLOO.—The Waterloo Electric Light Company has experienced considerable annoyance from the burning out of transformers by lightning. The repairs have to be made in Fort Wayne, often causing considerable delay. The company will solicit bids for putting up lightning arresters.

IOWA.

NEW SHARON.—The New Sharon Electric Company has just been incorporated.

ACKLEY.—The Ackley electric light and heating plant has been sold by Smith Bros. to John Rath.

SPIRIT LAKE.—This city has decided to expend about $6,000 in improving the electric light plant.

WASHINGTON.—The Iowa Gas & Electric Company is reported incorporated with a capital of $100,000.

NEWTON.—The Council will purchase a storage battery equipment for the electric light plant, at a cost of $8,000.

FORT DODGE.—The City Council has appointed a committee to investigate the construction of a gas and electric light plant, to be owned and operated by the city.

DAYTON.—The Dayton Heating & Lighting Company has been organized with C. D. Waterbury, president, and H. E. Nelson, secretary, and a capital of $10,000.

KANSAS.

BURLINGTON.—The electric light plant of this city has been purchased by G. H. Webb and G. Webb.

PITTSBURG.—The Pittsburg Railway & Light Company, of this city, has been organized with a capital of $600,000.

COTTONWOOD FALLS.—The Smith Light & Power Company, of Bolivar, Mo., has received a franchise from this town and is installing a plant here.

CHETOPA.—Burns & McDonnell, Kansas City, Mo., are preparing plans and specifications for water works and an electric light plant, to cost about $30,000.

ALMA.—The Mayor and Councilmen granted an electric franchise to the Alma Light & Power Company, which is composed of W. B. Wilson, G. A. Mueller and others.

KENTUCKY.

RUSSELL.—E. F. Fullerton and H. Willis, of Greenup, are reported interested in the construction of an electric light plant in Russell.

CAMPBELLSVILLE.—Articles of incorporation have been filed with the County Clerk at Campbellsville, Ky., to build and operate an electric light plant there, to be known as the Campbellsville Electric Light Company. The officers are: J. L. Adkinson, president; C. R. Davis, secretary and treasurer; B. S. Kincart, manager.

MAINE.

NORTH FAIRFIELD.—The Crosby Mercantile Company is to install an electric light plant which will provide light and power for its large interests here.

HOULTON.—There is a proposition to make a contract with the Maine & New Brunswick Electrical Company to furnish electricity for lighting, heating and power purposes to the town.

MARYLAND.

ELKTON.—The County Commissioners are stated to have granted permission to Wm. T. Harburton, president Elkton Electrical Light Co., to erect a pole line from Gilpin Falls, at Bay View, to Elkton, via Pleasant Hill.

BALTIMORE.—At the annual meeting of the stockholders of the Mount Washington Electric Light & Power Company, the following officials were elected for the ensuing year: President and general manager, Thomas W. Offut; vice-president, Alten S. Miller; secretary and treasurer, Harry J. McIntyre; directors, Thomas W. Offut, Alten S. Miller, S. Davies Warfield, Walter R. Townsend and Richard A. Bevan. The company is expending about $100,000 for the power house and new machinery, and will have the new plant in operation by Sept. 1.

MASSACHUSETTS.

CLINTON.—The Clinton Gas & Electric Company has decided to borrow $250,000, a part of which will be expended for improvements.

TEMPLETON.—A corporation will soon be formed under the laws of Massachusetts to furnish electric light and power in the town of Templeton.

LEOMINSTER.—The Leominster Electric Light & Power Company has secured the contract for lighting the city for the coming year at the following bids: 92 arc lights at $72 per year, each to burn until 1 a. m.; 20 arc lights to burn all night, at $110 per year, and 72 incandescents at $10 each; total cost, $9,976 per year.

MICHIGAN.

PLAINVILLE.—The Esele Light & Power Company has bought the franchise and the plant of the Brownell Lighting Company.

WEST BRANCH.—W. D. Eddy has been granted a 10-year franchise to operate an electric lighting plant at West Branch. He has bought the interests of W. W. Vaughn and will at once make improvements in the plant.

TAWAS CITY.—The Tawas Manufacturing Company will operate an electric light plant within a month. The plant is being installed by the city and the company will get its revenue out of commercial lighting.

HOUGHTON.—The Houghton County Electric Light Company will install an electrically driven, vertical, triplex pump at the Franklin pumping station, capable of supplying 65,000 gallons of water every 24 hours.

PORTLAND.—The municipal lighting plant will be increased in capacity by widening and deepening the race which conveys the water for power. W. D. Fargo, of Kalamazoo, will have charge of the work, which will be completed at a cost of $3,760. The plant will be shut down for at least four weeks.

LANSING.—The annual report of the municipal lighting plant shows a material gain. The cost of operating the plant in 1905 was $34,037.02, in 1904 it was $32,991.40. The increase in receipts from private consumers was $6,941.69, the total for 1905 being $41,858.12. The total earned receipts exceeded the operating expenses by $22,821.10.

ANN ARBOR.—The stock of the Washtenaw Light & Power Company is reported to have been purchased by Alex. Dow, of Detroit; R. W. Hemphill, Jr., of Ypsilanti, and others. The directors are reported to have decided to develop the Huron River power, manufacture gas and extend the power service in Ann Arbor and Ypsilanti.

MINNESOTA.

AUSTIN.—It is reported that the Electric Light, Power and Water Commission will expend about $20,000 for improvements at the electric light plant.

WARREN.—J. G. Robertson, of St. Paul, has secured the contract for a 125-h.p. boiler and engine for the electric light plant, and the Fort Wayne Electric Works, Fort Wayne, Ind., for a 75-kw. dynamo; total cost, $6,225.

INTERNATIONAL FALLS.—The International Light & Water Company has been incorporated with a capital stock of $50,000. The incorporators are E. W. Backus, W. F. Brooks, R. L. Horr and C. J. Rockwood, Minneapolis; H. V. Winchell, Butte, Mont.

MELROSE.—Contracts for constructing an electric light plant and water works have been awarded as follows: To the Dwyer Plumbing & Heating Company, of St. Paul, for plant complete, except electric portion, and to the American Electric Company, of St. Paul, for the electrical portion. Engineer, Oscar Claussen, St. Paul.

MISSOURI.

WEBB CITY.—J. C. Harrison and Robt. Holt, of Carthage, have petitioned for a franchise and contract to light Webb City.

CAMDEN.—The Camden Water, Light & Power Company, of Missouri, has filed a certificate designating Daniel Davies, of Camden, as agent for Arkansas, and that $30,000 of its $50,000 capital is in use in Arkansas.

KIRKSVILLE.—The Missouri Heat, Light & Power Company, of Kirksville, has been incorporated with a capital of $50,000, three-fifths paid. The incorporators are O. H. Davidson, of Des Moines, Ia.; W. B. Kinnish, of Adel, Ia.; J. H. Shively, of Perry, Ia.; C. H. Shively, W. T. Baird and M. D. Campbell.

ST. LOUIS.—The West Cabanne Improvement Company has filed an application for articles of incorporation for the purpose of furnishing light, heat and power in the city of St. Louis and St. Louis County. The capital is to be $25,000, half of which is paid. Thomas C. Henning owns a majority of the stock. Among the other stockholders are W. W. Colver, Arthur E. Ewing, Montague Punch, William Yule, Jesse P. Baker, George Kingsland, W. F. Funston and Charles E. Ware.

MONTANA.

LIVINGSTON.—An electric power plant, to cost about $60,000, will be established here shortly by Lewiston capitalists. John L. Bright is at the head of the project.

MISSOULA.—The Missoula Light & Water Company has ordered from the Westinghouse Machine Company a 500-kw., three-phase, 60-cycle, 2,200-volt Westinghouse-Parsons steam turbine. Other contracts for motor-driven exciter sets, switchboard material and surface condensing outfit have also been placed, the whole aggregating about $30,000.

HELENA.—The Helena Power Transmission Company, a subsidiary company of the Missouri River Power Company, is about to undertake the construction of a new dam and power plant on the Missouri River, about 15 miles below its present plant. The plant will have a head of about 60 feet and a capacity of about 20,000 horse-power, which will be transmitted to Helena, Butte and Anaconda. The Missouri River Power Company's transmission lines will be extended from Butte to Anaconda, making a total distance of transmission from the new plant to Anaconda of about 100 miles. The transmission will be operated at 70,000 volts. Mr. M. H. Gerry, Jr., is, as is well known, general manager of the Helena company.

NEBRASKA.

TECUMSEH.—An election will probably soon be held to vote on issuing $9,500 bonds for a new electric light plant. P. H. Hopkins, Mayor.

OMAHA.—An ordinance is before the Council providing for laying of electric wires underground within the district bounded by P street, 23d street on east, Q street on south, and 26th street on west.

NEVADA.

BISHOP.—Mr. W. Wayne Belvin, president of the British-American Finance Company, who returned to New York from a business trip to the new gold fields of Nevada, announced the organization of the Bishop-Nevada Electric Power & Lighting Company, with a capital of $1,000,000. Associated with him in the enterprise is James Butler, the original discoverer of the Mizpah mine at Tonopah; Clay Peters, a capitalist of California; Warner Miller, of New York, and a number of San Francisco capitalists. It is the purpose of the company to build an immense electric plant on the Owens River, near the town of Bishop in Nye County, across the line from Nevada in California and generate the electricity by means of water power to Tonopah, Goldfield and Bullfrog; and also to build and operate electric railways in the State of Nevada. The bonds of the company have been underwritten and the work of construction will begin at once.

NEW HAMPSHIRE.

PORTSMOUTH.—The Rockingham Light & Power Company is putting in a large new fan to be used for induced draft in the boilers and chimney at the power plant at Portsmouth, N. H. The company has also contracted with the Hodge Boiler Works, of East Boston, for the erection of a large tank to hold 135,000 gallons of feed water for the boilers. This will be taken directly from Beverly Springs.

NEW JERSEY.

SOUTH ORANGE.—The Village Board of Trustees has appointed a committee, with President Sinclair as chairman, to inquire into the municipal ownership of an electric light plant.

JERSEY CITY.—The Southern Power Company has been incorporated with a capital stock of $7,500,000. The incorporators are R. B. Harrington, E. B. Sperry and W. R. Journeay, Jr.

NEWARK.—The Board of Works has approved the resolution directing Morris R. Sherrerd, Chief Engineer and City Surveyor, to ascertain the cost of equipping either the Belleville or the Clifton Avenue pumping station as an experimental municipal lighting plant.

TRENTON.—The Northumberland County Ry. & Light Company has been incorporated at Trenton, N. J., with a capital of $1,000,000, to supply gas and electric light for cities and to construct outside of New Jersey railroads for the transportation of passengers and freight. Incorporators: Wilbur F. Sadler, Jr., Trenton, N. J., and Wm. W. Hepburn and Geo. Parkman, both of Philadelphia, Pa.

NEW YORK.

SPRING VALLEY.—The question of constructing an electric light plant at a cost of $25,000 is reported under consideration.

LITTLE FALLS.—Jas. G. Hazlett, City Clerk, writes that the Hudson River Power Company has petitioned for a franchise for lighting and power purposes.

NIAGARA FALLS.—The Niagara Falls Hydraulic Power & Manufacturing Company is reported to have decided to erect a new power house and improve the canal.

LOCKPORT.—The American District Steam Company is reported to have petitioned Council for a franchise to use the city streets and supply light, heat and power in Lockport.

ANDOVER.—The Andover Electric Power & Light Company, of Andover, has been incorporated with a capital of $10,000, by R. A. Stout, A. B. Richardson and J. H. Backus, all of Andover.

PARISH.—The Parish Lighting Company is reported incorporated, with a capital of $2,000, to manufacture gas for lighting. Incorporators: R. C. Robertson and Geo. Weaver, of Parish.

PAUL SMITH'S.—The Paul Smith's Electric Light & Power Company has been incorporated with a capital stock of $100,000. The directors are Paul Smith, Phelps Smith and Paul Smith, Jr.

CAIRO.—The Cairo Electric Light & Power Company has been incorporated with a capital stock of $80,000. The directors are C. E. Hewitt, M. G. Hubbard, Chatham, N. J.; F. G. Walters, Cairo.

TROY.—The Board of Contract and Supply is reported to be considering the question of establishing a municipal electric light plant to be used for lighting Monument Square and city buildings in that locality.

NEWBURG.—It is reported that the Cornwall Electric Light & Power Company will sell out to the Newburg Electric Light, Heat & Power Company. Capt. Thomas Taft is at the head of the Cornwall company.

OGDENSBURG.—It is reported that electric power, generated at Hannawa Falls, 30 miles from Ogdensburg, by the Hannawa Falls Water Power Co., is to be transmitted to this city for use of the Ogdensburg Power & Light Co.

LOCKPORT.—The Niagara, Lockport & Ontario Power Company has filed with the Clerks of the counties of Erie, Monroe, Orleans, Seneca, Wayne, Ontario, Cayuga and Onondaga certificates of extension of business in these counties.

TONAWANDA.—The Council is reported to have granted franchises to the Niagara Falls Electrical Transmission Company and the Niagara, Lockport & Ontario Power Company. Both companies must maintain their stations within Tonawanda.

NORTH CAROLINA.

SANFORD.—The town of Sanford is considering purchasing the electric light plant of the late A. F. Spooner. The plant is valued at $19,000, but can be purchased at about $6,500.

ASHEVILLE.—A meeting of the water and light commission will be held to consider the issuing of water bonds, and also $40,000 electric light bonds for constructing a plant on Swannanoa River.

GREENSBORO.—J. M. Bandy and W. H. Terrell, of Greensboro, are the engineers in charge of the development of water power on South Yadkin River for the Southern Yadkin Development Company. The work contemplated will cost about $1,000,000.

ALBEMARLE.—The Albemarle Light & Water Company has been incorporated with a capital of $25,000 by A. L. Patterson, J. M. Morrow and others, all of Albemarle. R. Smith, secretary, writes that the company is in the market for an outfit for a small electric light plant.

CHARLOTTE.—It is reported that the Catawba Power Company, of Charlotte, is seeking additional water power for electric development on account of their rapidly growing business and the increasing demand for power, which has about taken up all the available power in sight.

CHARLOTTE.—The Southern Power Company has been organized in New York City with a capital stock of $7,500,000, to develop large water powers on the Catawba River in North Carolina and upper South Carolina. The new company is organized under the laws of New Jersey, and Dr. W. Gil Wylie, of New York, is president; B. N. Duke, of Durham, N. C., first vice-president; W. S. Lee, of Charlotte, second vice-president and chief engineer. The offices of the company will be in Charlotte, N. C. The first power to be developed will be at the Great Falls of the Catawba, where a plant will be erected costing about $1,500,000.

OHIO.

GALION.—The Crawford Gas & Electric Company, recently organized here, is reported to be preparing to construct a power house here, at a cost of $75,000.

YOUNGSTOWN.—The Electric Supply & Construction Company, of Youngstown, has secured the contract for installing an electric light system at the new filter plant for $4,133.

BELLEFONTAINE.—C. W. Buchanan, Superintendent City Electric Light Plant, writes that bids will be received by the Board of Public Service, Aug. 10, for constructing a new electric light plant; probable cost, $50,000.

CANTON.—The Citizens' Light, Heat & Power Company has sold out to the Merchants' Heat, Light & Power Company. The new company is composed of Canton business men who have selected Thomas F. Turner as their president.

BELLEVUE.—The Mutual Light & Water Company has secured a franchise to light the streets by electricity. The company is about to be incorporated, with a capital of $50,000. The incorporators are E. C. Crocker, B. F. Bell, Peter Brady, and others.

NEWARK.—The Citizens' Electric Light & Power Company's plant and business, of Newark, has been sold to Congressman B. G. Dawes, Col. M. M. Gillette, and several other local capitalists, who have formed a corporation for the purpose of conducting the business.

COLUMBUS.—Recently the Council passed an ordinance fixing the rate for lighting purposes at 5 cent per kilowatt hour. The Columbus Railway & Light Company has enjoined the enforcement of the ordinance. Efforts of the City Solicitor to secure expert testimony to support the 5-cent rate have proven disappointing.

KENTON.—The Westinghouse Electric & Manufacturing Company, Pittsburg, Pa., is reported to be preparing plans and estimates for improvements and extensions to the plant of the Kenton Gas & Electric Company, recently purchased by Kerlin Bros., of Columbus. It is stated that about $50,000 will be expended.

NEWARK.—The Licking Light & Power Company, of Newark, has been incorporated. The concern has been reorganized by Melville Gillett, of Newark, and Congressman Beman J. Dawes, of Marietta. The capital is $300,000, one-third of which is preferred stock. In addition to Gillett, the incorporators are Henry G. Bohl, John P. Maynard, W. G. Bathalow and J. W. Danford.

COLUMBUS.—The municipal light plant has commenced to furnish electric current for the lighting of nearly the whole city. Under the new plan, there will be only one stretch in the city not lighted by the municipal plant, this being the distance between the court house and the Union Station in High Street, where the arches are still lighted by the merger company. It is the intention to permit the company to continue the lighting of the arches under yearly contract. A number of additional lights will be added to the municipal service, the plan contemplating eventually the use of 1,950 lamps.

OREGON.

SEASIDE.—The Seaside Electric Company has been incorporated by Dan. J. Moore, A. S. Froeled, and others.

ASHLAND.—Milton Berry, City Recorder, writes that the citizens voted to issue $50,000 bonds for constructing a municipal electric light plant.

OREGON CITY.—The Clackamas Power Company has been incorporated by J. T. Apperson, H. E. Cross, C. H. Dye, E. G. Canfield and I. B. Sanborn; capital, $25,000, with the object of erecting dams and developing power.

PENNSYLVANIA.

SHIPPENSBURG.—The Council has appointed a committee to solicit correspondence and secure information relating to cost and expense of constructing and operating a municipal electric light plant. The present contract does not expire until October, 1906.

GIRARDVILLE.—Bids will be received until Aug. 7 by M. J. Walsh, Chairman Light Committee, for lighting the streets with about 25 lights of the highest power for a period of 5 or 10 years, commencing Jan. 1, 1906, the annual cost not to exceed $1,500. Robt. Pryce, Clerk Town Council.

WAMPUM.—An election will be held in Aug. to vote on issuing $12,000 bonds to be used to build a gravity water system, and to equip the borough with electric light, power to be procured from the Ellwood Power Company, of Ellwood, 5 miles distant. G. B. Zahniser, Clendennin Blk., New Castle, is engineer for the water works.

LANSDALE.—Contracts for rebuilding the electric light plant have been awarded as fol-

lows: To the Erie City Iron Works, Erie, Pa., for the steam equipment, including one boiler and two engines and all connections; and the Fort Wayne Electric Works, Fort Wayne, Ind., for two dynamos of 125-kw. capacity and switchboard with all equipment and 60 enclosed arc lamps.

SOUTH CAROLINA.

ANDERSON.—At the annual meeting of the stockholders of the Anderson Water, Light & Power Company, Dr. S. M. Orr was re-elected president.

COLUMBIA.—A merger has been completed of the Columbia Electric Railway, Light & Power Company and the Columbia Water Power Company, and Edwin W. Robertson has been elected president of the new company. A new mortgage will be executed to cover a bond issue for the purchase of the water power company, leaving a considerable sum for contemplated improvements.

TENNESSEE.

CLARKSVILLE.—The Consumers' Electric Light, Power, Heating & Refrigerating Company is reported formed here to construct an electric plant.

TIPTONVILLE.—Papers are prepared for a 15-year franchise for an electric light plant to be in operation by September 1, 1905. It is understood that Memphis capital is behind the promoters of the new company.

CLARKSVILLE.—A movement has been inaugurated here to organize a new electric light and power company. The company will be known as the Consumers' Electric Light, Power, Heating & Refrigerating Company.

BOLIVAR.—Bids will probably be received early in August for the construction of water works and an electric light plant, for which bonds to the amount of $20,000 have been sold. Engineer, Granberry Jackson, Nashville.

KNOXVILLE.—In regard to the proposed power plant of the Knoxville Power Company on Tennessee River, Engineer Jas. B. Cahoon, of New York, states that it will probably not be financed before fall and nothing will be done until then.

CHATTANOOGA.—Local press reports state that plans are about completed for the proposed dam and power plant for the Chattanooga-Tennessee River Power Company, to be constructed under the supervision of Major Henry C. Newcomer, and work will begin about Sept. 1.

CHATTANOOGA.—The preliminary surveys for the proposed big water-power electric plant on Little River, near Blanche, Ala., are now being made. H. T. Henderson and Samuel Henderson, of Durango, Colo., are the principal promoters of the enterprise. It is expected that the work will cost between $1,000,000 and $1,500,000. The company proposes to develop sufficient power to furnish the industrial plants of Gadsden, Alabama City and Attalla, Ala.; Rome, Ga., and probably Anniston, Ala. The proposed plant will be located 34 miles from Gadsden, 27 miles from Rome, and 72 miles from Anniston.

CHATTANOOGA.—W. B. Spencer, 16 Exchange Place, New York, N. Y., Assistant Engineer of the Chattanooga-Tennessee Power Company, of which J. C. Guild and C. E. James are the promoters, writes that bids for construction of the plant, which will cost about $1,500,000, will be received in about 4 weeks. This water power electric plant, which will be constructed on Tennessee River, about 12 miles from Chattanooga, will develop about 50,000 horse-power. The lock will be about 60 feet wide, dam 40 feet high and 1,200 feet long; power house to be adequate for 14 units of 3,000 kw. each. Transformer house and other buildings will be erected. John Bogart, Consulting Engineer, 16 Exchange Place, New York, N. Y.

TEXAS.

CENTER.—The electric light plant owned by Fleshman & Harkrider has been destroyed by fire.

BONHAM.—The Bonham Electric Light & Power Company's plant was sold to a Dallas firm, of which J. F. Strickland is president.

CLARENDON.—The Clarendon Water, Light & Power Company has been organized with a capital stock of $50,000. L. W. Chase is one of the incorporators.

COLUMBUS.—The Columbus Light Company has been organized at Columbus for the purpose of operating an electric light and power plant. The company has a capital stock of $10,000.

SAN ANTONIO.—C. A. Zilker, vice-president of the Southern Ice & Cold Storage Company, of San Antonio, is promoting the organization of a company to install an independent electric light and power plant for San Antonio.

AUSTIN.—Mayor W. E. Shelley, of Austin, is negotiating with the representatives of a syndicate of Boston capitalists for the sale of the ruins of the old dam across the Colorado River here, and the sale or lease of the municipal water and lighting plant. This dam was built about ten years ago at a cost of $1,000,000, but was destroyed by a flood in the river in 1900. It supplied power for operating the water works and electric light plants of the city.

UTAH.

COALVILLE.—The citizens have voted to issue $10,730 bonds for an electric light plant.

PROVIDENCE.—It is proposed to construct an electric light plant, at a cost of $12,000. A. M. Hammond is town clerk.

EPHRAIM.—Bonds to the amount of $15,000 are reported sold, to be used for the construction of an electric light plant.

VERMONT.

BRISTOL.—The Lake Dunmore Power & Traction Company, which recently absorbed the Bristol Electric Company, is constructing a steam auxiliary plant and has completed surveys for a large dam to be built about a mile above its present plant in New Haven River. H. W. McIntosh, of Burlington, is the engineer.

ST. JOHNSBURY.—An important business deal has just been completed by which the St. Johnsbury Electric Company acquires the Ide water power at Passumpsic, and will erect at once a modern electric light station, using the water power to its fullest capacity. The Electric Company will then have three stations, one at the dam at the Center, which now supplies the village with arc and commercial arc lights, the station at the Belknap dam, and the new one at Passumpsic.

VIRGINIA.

RURAL RETREAT.—W. C. Lawson contemplates installing an electric light plant at the Rural Retreat Mills, and will probably furnish light and power to the town.

FREDERICKSBURG.—The Rappahannock Electric Light & Power Company has been formed by J. B. Ficklen, president; A. D. Tapscott, secretary. The capital is $10,000.

JOHNSON.—There has been talk of installing the electric plant at Ithiel Falls and it is understood that the town has purchased the water power of Rev. I. T. Johnson, and that the plant is to be established there.

RICHMOND.—The Water Commission has adopted the report of the sub-committee endorsing the proposed new electric light plant at the old pump house, to cost, for building, $12,000; for electric pumps, motors, transformers, switchboard, transmission line, etc., $25,000, and for a main between pump house and new reservoir, $52,000.

POULTNEY.—The Lake Dunmore Power & Traction Company, which recently absorbed the Bristol Electric Company, is building a steam auxiliary plant and has completed surveys for a large dam to be about a mile above its present plant on the New Haven River near Bristol. The former company operated its plant only a portion of each day, but the new concern proposes to furnish power 24 hours each day.

WASHINGTON.

TACOMA.—The City Council granted a franchise to the Seattle-Tacoma Power Company.

KENNEWICK.—C. E. Wood, of Genesee, has petitioned Council for a franchise for water works and an electric light plant.

PORT TOWNSEND.—John Seiderbaum has petitioned Council for a franchise for a gas, electric light and heating plant.

SNOHOMISH.—The plant of the Snohomish Electric Light & Water Power Company is reported to have been destroyed by fire.

FORT LAWTON.—The Seattle Electric Company, of Seattle, has submitted the lowest bid for installing electric light at Fort Lawton, for $13,576.

TACOMA.—The Fire and Water Committee has recommended the passage of a resolution authorizing the City Clerk to call for bids, to be submitted by Oct. 1, for the construction of a water-power generating plant of not less than 5000 horse-power and not more than 10,000 horse-power.

WALLA WALLA.—An ordinance has been introduced in Council granting C. M. Maxwell and H. Day Hanford, of Seattle, a franchise to construct and maintain an electric light and gas plant in Walla Walla. It is proposed to organize a company to be known as the Walla Walla Gas & Electric Co.

TACOMA.—The City Council on July 12 adopted the resolution authorizing the City Clerk to procure bids for the construction of a steam power electric generating plant, to be established if possible within the city limits. All bids to be submitted for a generating plant of at least 5,000 horse-power, and not more than 10,000. A resolution was previously adopted for a water power generating plant. The idea is to secure bids on all kinds of plants for generating electric current.

WYOMING.

EVANSTON.—The local electric light company has applied for a franchise for laying steam pipes, to supply heat to business houses.

LARAMIE.—The City Council is reported to have granted Alfred E. Kalter, of Indianapolis, a franchise for an electric light plant.

CANADA.

NAPANEE, ONT.—The citizens have voted to issue $35,000 bonds for a municipal electric light plant.

NIAGARA FALLS, ONT.—The diverting dam in the Niagara River, which has shielded the intake works of the Ontario Power Co. during their construction, is now being rapidly and successfully removed. This dam was built in 1903, extending out from shore above the upper line of rapids and laying dry an area of about 18 acres, including the water courses about the Dufferin Islands. In June water to operate the first 10,000 h.p. unit was admitted to the forebays by a sluiceway cut through the dam. This diverting dam is about 900 feet long, 250 feet of it extending out from shore at nearly a right angle, and the remainder running at an angle down the stream, thus turning the water out toward the middle of the river. It is built of bottom cribs 31 feet long, 16 feet wide and 11 feet deep, which were floated into place, and sunk by loading with stone. No puddle was used, but the dam was made tight by bags of cement placed on the rock bed of the river against the upstream face of the cribs, and by double-lapped tongue and groove sheet piling driven into these bags. A diver, protected from the swift current by a timber shield, placed the bags of cement and fitted the piling to conform to the irregularities of the river bed. This construction has proven very successful, as very little water has leaked through the dam. The removal of the dam is accomplished by unloading sections or cribs one at a time, and by swinging as on a hinge in toward the shore, into the quiet water behind the remaining portion of the dam. The stone fill is removed by common labor, no diver being required. An interesting, and in fact surprising, feature of the operation of removal, is that after a crib is unloaded, in spite of the terrific force of the current, it seems almost as stable as before, although held in place only by the small quantity of cement above mentioned. The combined power of a hoisting engine on shore and a derrick on the dam is required to loosen the cribs from the bed of the river, after which they swing easily around toward the shore.

American Electrician.

Vol. XVII. New York, September, 1905. No. 9.

MODERN FRENCH HYDRO-ELECTRIC GENERATING STATION.

THE SAUT MORTIER TRANSMISSION PLANT.

BY F. M. BRYAN.

A good example of the use of a hydro-electric plant for distributing current over a wide area of country is found in the Saut Mortier plant. It is located in the Jura region, a mountainous district lying in the eastern part of France and next to Switzerland. What is to be noticed in the present case is the use of current over an extensive region comprising a great number of small towns and villages, where manufacturing industries are carried on in many small factories and home workshops. Watchmaking, for instance, is an industry which takes a great number of small motors, and there are also many turning mills, diamond polishing establishments, etc. Where hand, steam or water power were formerly used, electric motors are employed for the most part, since the erection of the present plant, and the supply of current has proved a great benefit to the region. The electric lighting of the different towns is carried out at the same time.

FIG. I.—HYDRO-ELECTRIC POWER PLANT AT SAUT MORTIER.

The large hydraulic plant erected on the Ain at Saut Mortier is among the most important of the Alpine region. The Ain River is a rapid mountain stream, which rises in the Jura Mountains and runs through several districts, emptying into the Rhone. It is subject to great fluctuations and special measures had to be taken to provide for this when designing the hydraulic work of the plant. The Union Electric syndicate is operating the Saut Mortier plant, and the whole of the electric equipment was installed by the Oerlikon Company. As the river could not supply all the water needed to operate the turbines, use was made of Lake Chalain, a small body of water forming a natural reservoir, which is separated from the stream by only a mile or so of alluvial soil. The level of this lake is about 110 feet above that of the river. The lake affords a basin of one square mile and is 120 feet in depth. During droughts it can be called upon for a good supply, so that the present hydrau-

lic plant can develop 3,000 horse-power with a 60 foot head of water.

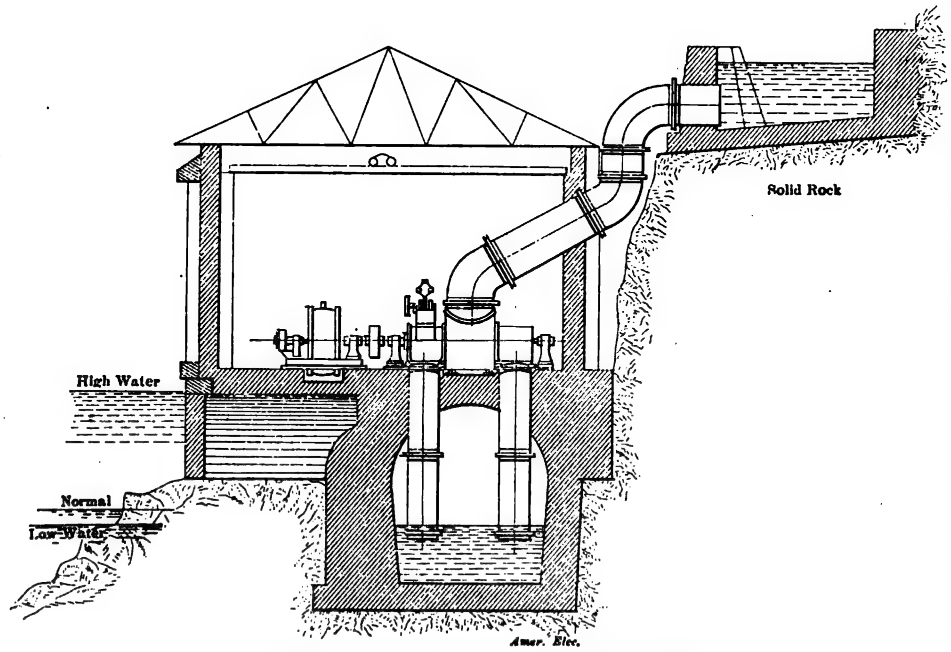

FIG. 2.—CROSS-SECTIONAL ELEVATION OF POWER HOUSE.

The lake is connected with the river by an underground canal, which has a series of gates for regulating the supply. The remainder of the hydraulic work for the Saut Mortier plant comprises a dam across the Ain, which is 32 feet high and 150 feet long, a masonry canal leading from the dam about a mile in length, which is covered over for a distance of 400 feet, and is open for the rest of the way, and an underground passage leading to the turbine station. An overflow canal provided with gates is placed above the station to adjust the height of the water.

The dam is located at a narrow part of the river, where it has worn a deep gorge in the cliffs, on a rock foundation. The top width of the dam is about 12 feet. The upper part of the dam has been constructed so that the highest load will not exceed 12 tons per square foot. On the right hand side of the dam are three locks for navigation, and at this point the main canal for the station starts. The main flume, which leads from the dam to a point above the station, has a rectangular section, and is 15 feet wide and 9 feet deep. This canal is built of concrete and is partly open and partly covered. At several points the canal has overflow gates for regulating the level. At the end above the turbine house it empties into a collecting basin built of masonry. The bottom of the basin is about 60 feet above the level of the station floor. The penstocks, of which there are four, are built of 8 millimetre steel and measure 70 inches inside diameter. Fig. 2 shows the disposition of the basin, penstocks and wheels, and Fig. 1 shows the exterior of the station. Some difficulty was experienced in constructing the station, as the river is bordered by high banks with but little level ground. The hydraulic work had also to be designed so as to provide for the sudden rises which are very frequent in this mountain stream. The building, which measures 150 by 50 feet, has been constructed for five turbo-generator groups. At present there are four of these units installed. Concrete is used for the foundation and walls and the floor of the main room is tiled. The cables leading from the generators are provided with conduits covered with flat stone. A 15-ton overhead crane runs along the main room. The Saut Mortier plant is in constant operation except for a stop of an hour and a half at

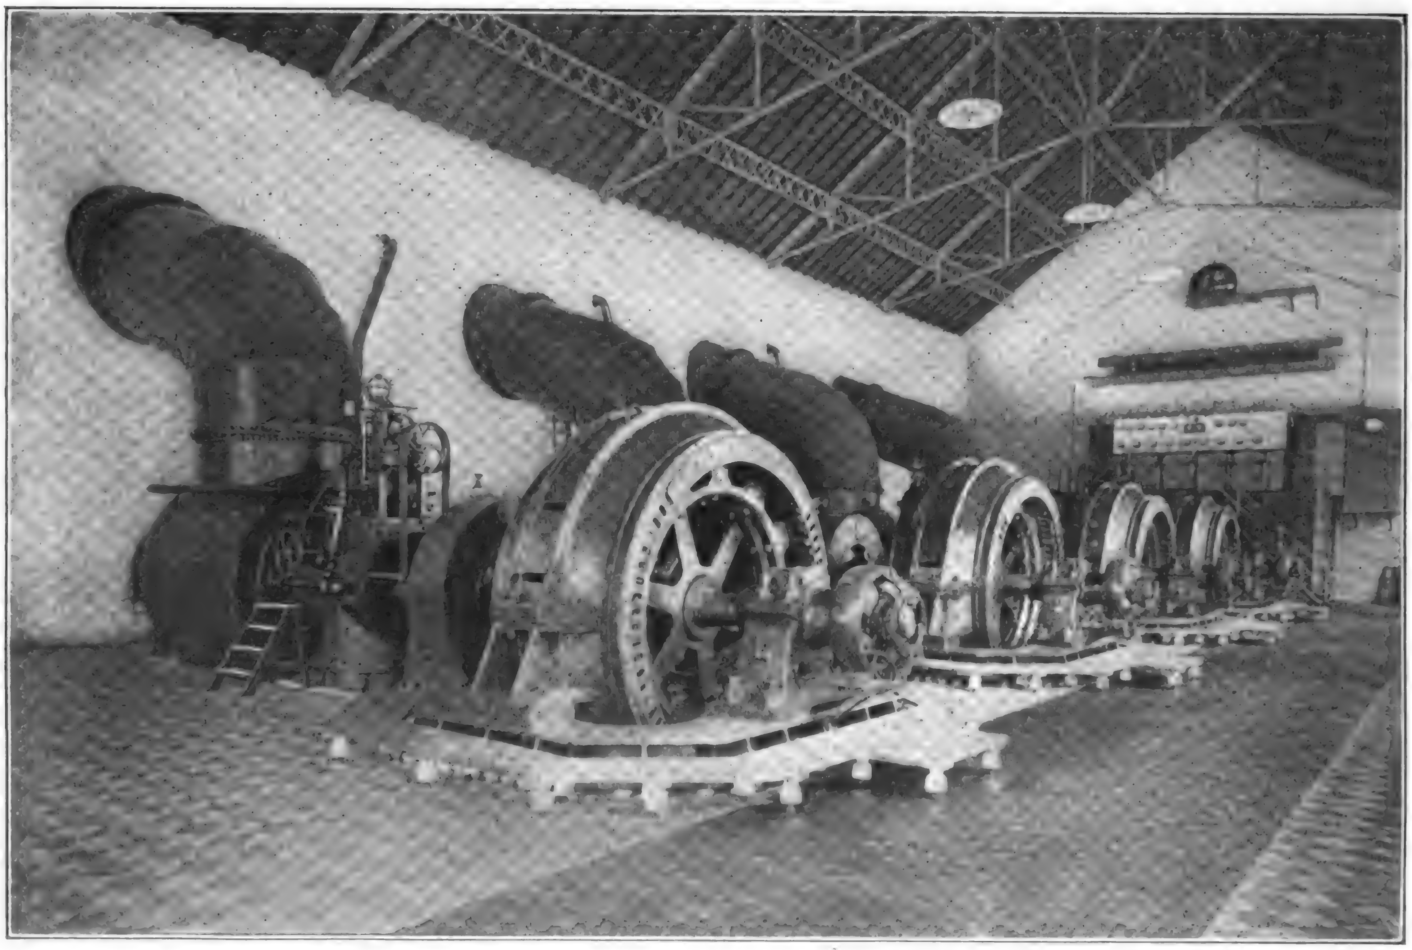

FIG. 3.—INTERIOR VIEW OF THE STATION AT SAUT MORTIER.

midday and again for six hours on Sundays.

The general appearance of the turbines, which have been built by Piccard & Pictet, of Geneva, will be observed from Fig. 4. These wheels are of the horizontal shaft pattern and have been specially designed so as to allow for sudden variations of the water supply. They work on a head of water averaging 18.4 metres (60 feet), and develop 700 horse-power each, at 250 r.p.m. At certain periods of the year when the fall is reduced to 40 feet, the turbines furnish 500 horse-power, or more. Raffard elastic couplings connect the turbine shafts to the alternators. The main shaft of the turbines is placed 22 feet above the level of the tail race, which is an advantage in case of high water. Each turbine of the series is built with two wheels in the same outer casing. The water is discharged from the wheels by a double piping, which is placed on each side of the main chamber. The outside diameter of the turbine wheels is 42 inches. They are surrounded by a set of movable inlet vanes which regulate the water supply. A Piccard hydraulic governor is provided for each turbine. It consists of a hydraulic motor whose movements are controlled by the speed of the wheel. The motor is connected with the movable vanes, opening or closing them as the speed rises or falls. In practice the speed of the turbines is kept constant within very close limits.

The alternators are of the Oerlikon inductor type. They deliver 50-cycle, three-phase current at a terminal voltage of 7,500, with a speed of 250 r.p.m. The revolving field is made up of a cast-steel rim bolted to a cast-iron wheel having 6 spokes. The spokes are stiffened with strong webs. The outside diameter of the rim is 1,890 metres, its width 920 millimetres and its thickness 125 millimetres. A double set of laminated pole-pieces is disposed around the periphery of the wheel, and bolted to the rim. The height of the pole-pieces is 150 millimetres, and the width of each pole, measured parallel to the shaft, is 235 millimetres, while the peripheral length of the pole face is 230 millimetres. The outer diameter of the revolving field is 2.192 metres, and the air-gap is 4 millimetres. Between the two halves of the field is a winding which passes around the main wheel and forms a double magnetic circuit. This winding is of copper band, having a section of 60 by 2 millimetres. The field winding is made in two halves, and each half contains 83 turns. The two halves of the winding are connected in series upon the exciter circuit. The current is conveyed by a pair of rings mounted on the shaft. The total number of turns in the field is 166, and the total weight of copper is 13.7 tons. The entire revolving part of these alternators weighs 84 tons.

The outer body of the machine which contains the armature winding is formed of a cast-iron ring, built in two parts. The ring has a trapezoidal section in each of the halves and the latter are connected across by a cylindrical part having a series of 12 ventilating holes. The outer diameter of the main casting is 3.090 metres and the width, 0.900 metres, while the inner diameter is 2.540 metres. Inside the casting is fitted the laminated part which carries the coils. To correspond with the field, the armature is built in two parts, and each half of the main casting thus carries a similar laminated ring. The latter is bolted to the casting and one of the rings is disposed so that it can be taken out, if necessary. The outer diameter of the laminated ring is 2.540 metres, and its thickness is 170 millimetres. The armature bore is 2,200 millimetres, and the width of each ring, 250 millimetres. The coils are placed in 72 slots, two slots per pole and per phase. There are two lathe-wound coils laid in each slot. The coils are insulated with micanite, and are held in place by fibre strips. Each armature coil is made up of 33 turns of two 3.2 millimetre copper wires in parallel. The coils of each phase are connected with the corresponding coils which lie in the slots of the other ring. The total weight of copper in the armature winding is 600 kilogrammes. The fixed portion of the alternator weighs some 17 tons.

Under the body of the machine are placed the main connections for the current and these are completely protected. From here the cables pass in conduits under the floor to the switchboard. The exciting current at no load is about 56 amperes. When under the usual running conditions of 50

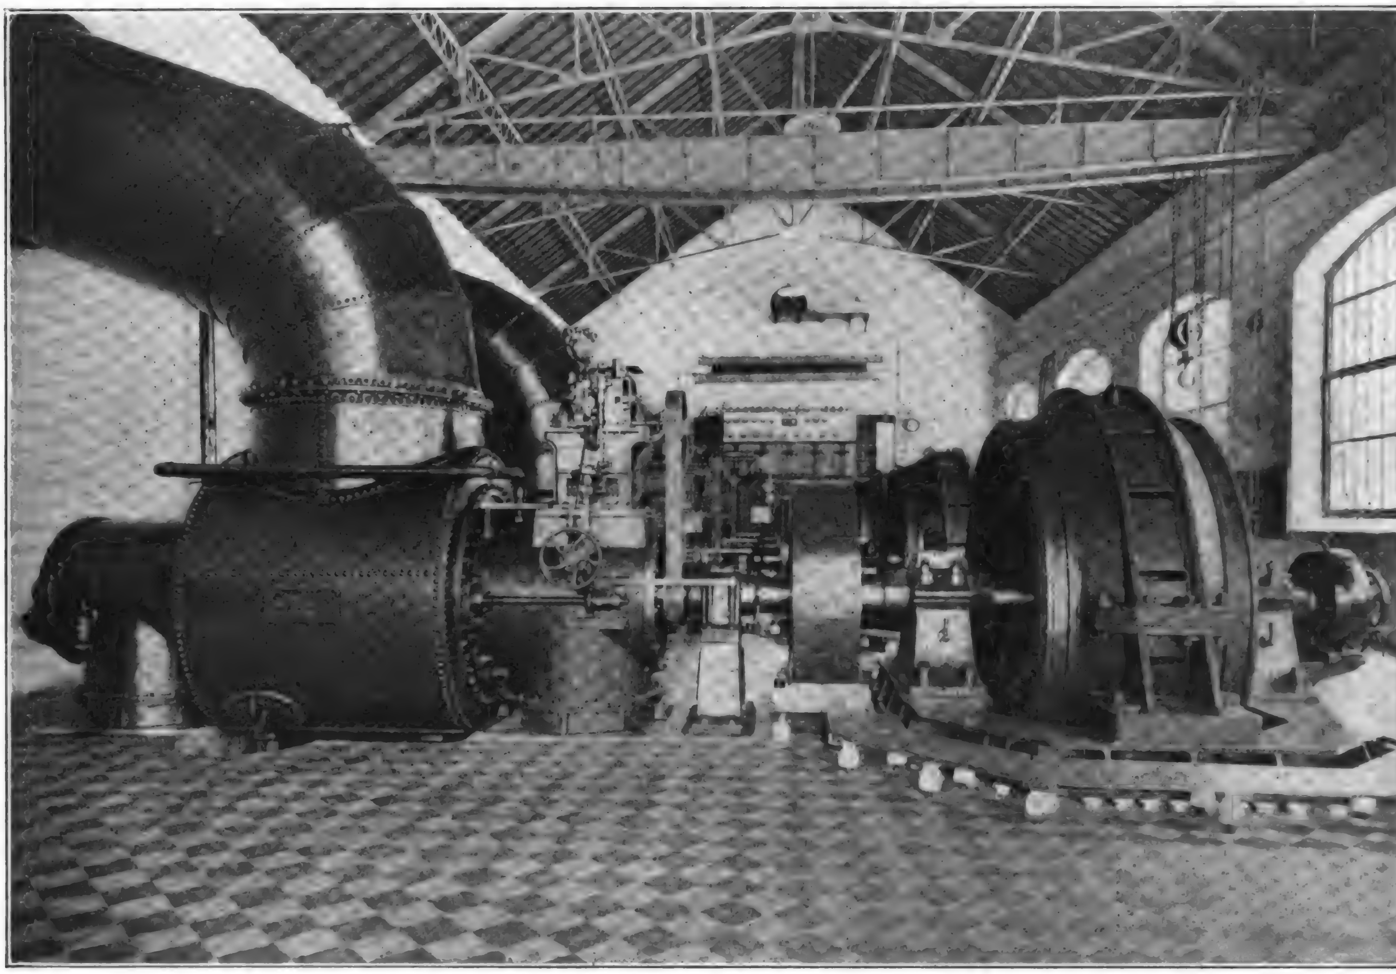

FIG. 4.—VIEW THROUGH THE CENTER OF THE STATION.

amperes per phase and a power factor of 0.8, the exciting current is 90 amperes. The efficiency of these alternators at normal load with a power factor 0.8, it is stated to be 93.5 per cent. The losses are given as follows: Losses at no load, 24,300 watts; heat loss in armature, 10,300 watts; in field, 1,810 watts; total loss in the machine, 36,410 watts.

As will be observed, the exciters of the machines are mounted on the end of the shaft, outside the main bearing, and are held upon a bracket. The exciters are 4-pole, shunt-wound machines with drum armatures, and have a capacity of 3.6 kilowatts at 30 volts.

The switchboard installation of the Saut Mortier plant has been well carried out. In order to provide sufficient space for the great number of circuits which are used here, the switchboard is built in two stories and is placed against the end wall of the station. The upper part contains the marble switchboard proper, while the lower part has most of the apparatus and the bus-bar connections. A platform is placed in front of the main panels which carry the hand-wheel and levers, so that the attendants can overlook the dynamo room. An iron structure measuring 25 feet long and 15 feet wide forms the main platform, and serves to hold the upper part containing the panels. An iron staircase leads up to the main platform on either side. The upper story consists of an iron frame which carries a set of white marble and xylolith panels for holding the measuring instruments. The switchboard is 15 feet long and 7 feet high and stands 5 feet from the wall of the station. There are ten panels in all and each has a corresponding set of instruments. Under the main panels is another set of panels which serves to hold the connecting wires on the back, while in front are mounted the levers and hand-wheels connected with the switching apparatus in the lower story. All the switchboard panels, with the exception of the upper middle one, carry ammeters for the alternators and feeder circuits. The latter panel has a general voltmeter which can be connected to the different circuits by a voltmeter switch. Behind the panels are the instrument wires and the lightning arresters.

The lower chamber containing the switching apparatus is accessible from the ends, and is divided into two parts by a central passage. The side next the hall carries the high tension switches for the machines, as well as the resistances, the reducing transformers for the measuring instruments and the cables coming from the alternators. On the side next the wall are the safety devices for the different feeders of the line.

The high tension switches of the feeder circuits are placed above the middle passage on the ceiling. Here are placed switches and special safety devices which have been recently designed by the Oerlikon Company. These devices work on the blow-out principle, having the arc enclosed in a chamber.

The main lines which run from the Saut Mortier station are four in number and they cover a considerable extent of territory in the Jura region, running through or near many towns of large size or smaller villages which are fed either by the main lines or by branch circuits. Of the four main lines at high voltage, the first circuit runs through the country for a distance of 16 miles to the large town of St. Claude, which is an industrial center of some importance. The overhead line consists of two separate circuits, each having two wires of 8 millimetres. Another main line runs from the station as far as the town of Nantua. For a distance of 6 miles the line uses three 8 millimetre wires, and from this point a double circuit branches out. The first branch leads to Nantua, 12 miles off, with a circuit of three 6 millimetre wires, while the second branch of three 4-millimetre wires leads to the town of Viry, 5 miles off. From the latter point there are a number of shorter branches which lead to the surrounding localities. The third line from the station is 5 miles long, and goes as far as the town of Arinthod, with three 4-millimetre wires, while the last circuit, leading for 3 miles to Cernon, runs from there to Moirann, 6 miles, with 4-millimetre wires. The total length of the high tension overhead lines starting from Saut Mortier may be reckoned at 70 miles. On the same poles is mounted a telephone circuit. There are in all some 4,000 poles now in use on the different lines, and these vary from 30 to 40 feet in height. They

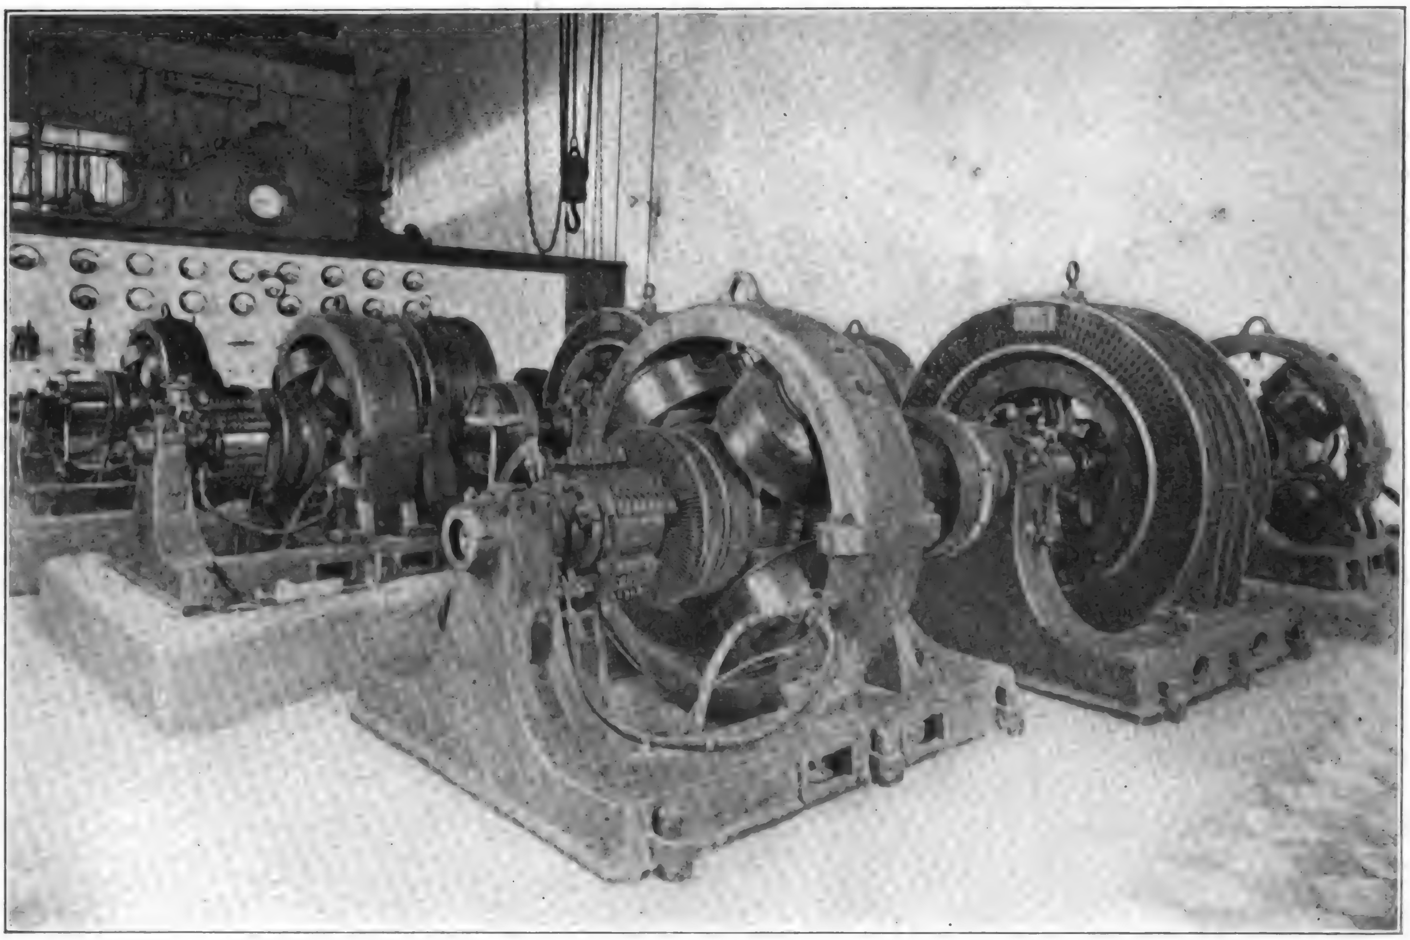

FIG. 5.—INTERIOR VIEW OF THE SUB-STATION AT ST. CLAUDE.

are treated for the most part with sulphate of copper or zinc chloride, and are sunk six feet in the ground.

Lamps and motors in the different towns are supplied by secondary circuits, and the transformers which are used here are installed in kiosks built of cement and located at the proper points. Each of the transformer posts has a similar outfit comprising a 3-pole switch for the high and low tension circuits, safety fuses, and lightning arresters for primary and secondary circuits. The lines from the transformer houses are overhead in all cases. A 70-kw. Oerlikon transformer is generally used on the different posts.

In order to supply current for the locality of St. Claude, where the number of lamps and motors is considerable, a sub-station has been erected, containing a number of motor-generator groups. Fig. 5 is a view of the St. Claude station and shows the main room, with the motor-generators in front and the main switchboard in the rear. The sub-station consists of a two-story building, each floor covering some 250 square yards. Three motor-generator sets are mounted in the dynamo room, and each of these groups consists of an Oerlikon three-phase motor having a generator mounted on either side of it and connected by a flexible and insulated coupling. The three-phase motors are of the most recent construction and operate at 590 r.p.m. Their capacity is 150 horse-power each. Transformers in the station lower the line voltage to 200 volts for the motors which work on 50 cycles. The bore of the stator is 900 millimetres, with a length of iron of 230 millimetres. In each of the 130 slots which the laminated ring carries there is placed a cable formed of 14 bare copper wires of 3 millimetres. The rotor of these machines has an outside diameter of 898 millimetres and carries 180 slots. In each of the slots is laid a cable formed of six 4-millimetre bare copper wires.

The direct-current machines on either side of the motor are of the standard Oerlikon 75 horse-power pattern, with a 4-pole field and a drum armature. These machines work at normal speed of 590 r.p.m. and deliver current to the secondary circuits at 200 volts. The diameter of the armature is 470 millimetres and the length of iron 320 millimetres. The armature has 117 slots, each containing two cables formed of three 4-millimetre wires. The field diameter is 486 millimetres.

The apparatus in the St. Claude station comprises four main, three-phase transformers which are used to supply the motors of the groups just mentioned. The high tension lines coming to the transformers are supplied with safety fuses and lightning arresters. The switchboard carries switches for the alternating and direct-current circuits, which leave the station for supplying lamps and motors in St. Claude. The three-phase lines are used for the motors throughout the locality, while the direct-current lines serve for the public and private lighting.

A considerable number of three-phase motors are used in the different industries at St. Claude and in the neighborhood, and the number is constantly increasing. The three-phase circuit supplies the motors at 200 volts. These latter are of Oerlikon make and range in capacity from one-half to 35 or 40 horse-power. At the present time there are upward of 100 motors in use. The lamp circuits in the different localities fed by the Saut Mortier plant are supplied with three-phase current at 120 volts. In St. Claude there are also a number of lamp circuits which work on direct current at 200 volts, with two lamps in series. It is estimated that there are upward of 7,000 lamps used throughout the region.

PISTON ROD PACKINGS.

BY R. T. STROHM.

The common means of obtaining a steam-tight joint around a piston rod or a valve stem is by the use of a stuffing-box and gland, as shown in Fig. 1. The stuffing-box *A* consists of a circular projection cast with the cylinder head, and having a greater internal diameter than the diameter of the piston rod, so as to leave an annular space between the sides of the stuffing-box and the rod, into which several layers of packing are pressed. The gland *C* is made of such proportions that the cylindrical portion surrounding the rod will slide easily into the bore of the stuffing-box. This

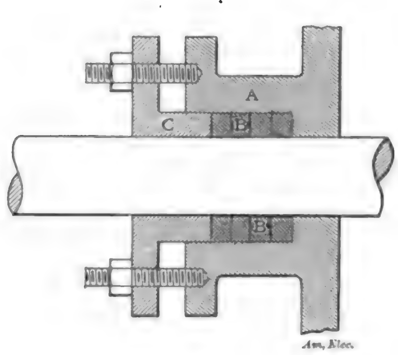

FIG. 1.

gland is forced down upon the packing rings by means of bolts and nuts which draw it toward the cylinder; the packing is thereby compressed and forced to expand laterally, causing it to fit closely around the rod so as to prevent leakage of steam.

A good piston rod packing must embody certain essential features. In the first place it must be pliable enough to adjust itself readily to the shape of the rod. Unless this is the case, leakage is certain to occur. It must also be possessed of reasonable durability. There are three deteriorating agencies at work on the packing when it is in service in the stuffing-box. First, it is subjected to the pressure of not only the steam, but also the gland; second, it is subjected to the heat of the steam, the temperature which it must withstand on this account depending upon the steam pressure; third, it must bear the friction and consequent wear due to the reciprocating motion of the rod.

In order to withstand comparatively high pressures with any degree of success, a fibrous packing must possess a certain "body," or firmness. Otherwise, it will be too easily disintegrated and liable to be torn out of the stuffing-box by the friction of the rod combined with the pressure of the steam. But, on the other hand, pliability must not be sacrificed to obtain firmness.

In order to insure pliability, the packing must not dry out or harden. As soon as this occurs there will be increased friction, and the heat thus generated will make the packing still harder and drier, with the result that it will eventually seize the rod. This results in scoring and fluting, for, in spite of the fact that the fibrous materials incorporated in ordinary packings are softer than metal, they are able, when dry and hard-baked by heat, to cut and ruin even a steel piston rod.

All fibrous packings include lubricants of some sort in their make-up, and these serve both to give the requisite pliability and to prevent undue friction with the rod. The lubricants thus employed are mineral oils and graphite. It should not be necessary to put great pressure on the packing, by screwing down the gland, in order to secure a steam-tight joint. Undue pressure in this way not only adds to the friction and wear but shortens the life of the packing and that of the rod.

Fibrous packings are made in three styles, one of which is known as coil packing, because it is put up in a continuous strip resembling a length of coiled rope. A sufficient number of short pieces are cut from this to make enough rings to fill the stuffing-box properly. These rope packings are usually of circular or elliptical cross-section, and vary by 1/8 inch in their sizes, although some makers supply sizes varying by 1-16 inch. In this same class may be mentioned spiral packings, which are put up in continuous lengths wound into helical form. These require to be cut also before being applied.

Another class includes ring and sectional packings. In this class the packing rings are already molded into the proper shape and size, and are ready to be applied at once to the rod. This is a very convenient form, and enables one to pack a rod quickly and easily.

The third and last comprises what are known as sleeve packings. As the name signifies, these are long sleeves of packing material; they are built up of successive rings, but all are held together in a single piece. Such a packing must be made to fit both the rod and the stuffing-box snugly when first put in place; otherwise there will be danger of leakage.

The first packings used were made of strands of flax twisted together loosely and rendered pliable by a thorough coating of tallow worked into the fibers. This was wound around the rod in a helix until of sufficient amount to fill the stuffing-box. The trouble experienced with this crude form was its rapid drying out and hardening, resulting in a blowing through of steam. To obviate this, the experiment was made of putting rubber inside the flax, so as to give the packing resilience. The re-

sults were thoroughly satisfactory. Not only was it possible to maintain a tight joint for a greater length of time, but at the first sign of leakage the gland could be screwed down a little and the natural

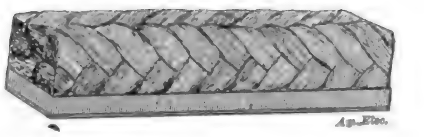

FIG. 2.

elasticity of the rubber would keep the flax against the rod at all points. The natural result of this development was the extensive and almost universal adoption of rubber as a component part of rod packings.

An extremely simple form of packing is shown in Fig. 2, consisting of flax and rubber. The flax is woven into a square braid, as indicated, and this is backed by a layer of soft rubber. When placed in the stuffing-box, the upper surface of the flax lies next to the rod, and the rubber farthest from it. Upon tightening the gland, the expansion of the rubber towards the rod causes the flax to be set up tight.

Among the coil packings, the best known is the gum-core style, a short section of which is illustrated in Fig. 3. A rectangular core of pure rubber is covered with successive layers of flax or cotton-duck, the

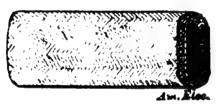

FIG. 3.

fibrous material being saturated with high-grade lubricants. The longer side of the rectangular center is parallel to the rod when the packing is in position. Rope packing is also made circular in section, the core being round, but the rectangular shape is most used, since it will permit being "followed up" to a greater extent than the round form.

Engineers differ somewhat in opinion as to how coil packing should be cut for packing a rod. Some cut the ends so that when the piece is bent into a ring around the rod the two cut surfaces are square and parallel. Others cut the coil diagonally so that the ends overlap. No matter which method is followed, the ends should not meet when the packing is first placed on the rod, but should be separated an eighth of an inch or more, because the packing when compressed by the gland and acted upon by the heat of the steam, swells, and

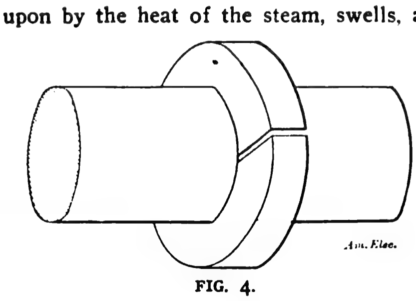

FIG. 4.

allowance must be made for this. The joints of the successive rings should be staggered, or "broken," the joint of one ring being placed diametrically opposite the joint in the next adjacent ring. In general, it will be found more satisfactory to cut the sections with beveled ends.

Where an engineer has a large number of rods to pack, and at short intervals, it will be found convenient to have mandrels of hard wood of diameters corresponding to the various rod diameters. In using rope packing the piece is simply bent around the mandrel and cut at an angle with a sharp knife, somewhat as indicated in Fig. 4. Such a device is not necessary, of course, where ring or sleeve packings are used. Instead of the wooden mandrel, a trough or box similar to the miter box used by cabinet makers may be substituted; the various lengths required for rods of different diameters can be marked along the side or edge of the box.

In case the packing is to be subjected to steam of high pressure, and consequently of high temperature, the materials used

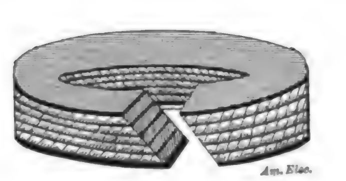

FIG. 5.

must be able to withstand such conditions. For this service, numerous combinations of asbestos and soft metal have been used in packings, the asbestos giving the necessary heat-resisting qualities, and the metal the requisite strength to resist the pressure. Usually, a soft rubber core of rectangular section is covered with asbestos threads, finely braided, alternating with layers of soft metallic wire, the whole being covered with cotton duck to prevent actual contact of the asbestos fiber and the rod. Sometimes

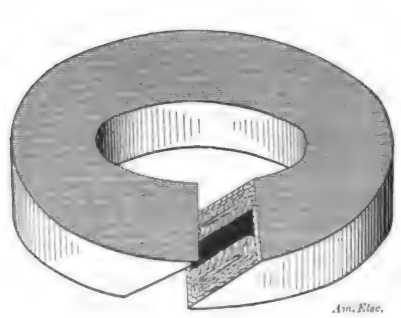

FIG. 6.

the outside layer consists of soft brass or copper wire, intended to add to the wearing qualities of the packing.

Ring and sectional packings are made in various sizes and styles to fit any diameter of rod and any size of stuffing-box. These forms of packing are very easily handled and easy to apply, since no cutting and fitting are required, if the proper size of ring has been secured. A common form of ring packing is shown in Fig. 5. It consists of alternate layers of rubber and cotton duck, thoroughly lubricated. These rings should be ordered to exact size, so as to fit both the rod and the stuffing-box snugly, because the rubber layers lie at right angles to the rod, so that there will be little expansion laterally, the greater amount being lengthwise of the rod.

The reverse is true of the ring packing shown in Fig. 6. This consists of a narrow ring of rubber lying parallel with the rod, and on either side of the rubber, cushions of cotton or flax fibers closely woven, the whole being held together by an outer

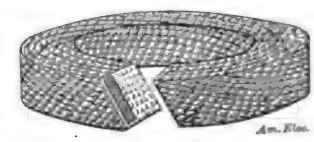

FIG. 7.

casing. It is evident that the pressure of the gland upon a ring of this character will compress the rubber center and cause the ring to expand toward the rod as well as toward the wall of the stuffing-box. Hence, rings like these should be quite free when placed in position, sliding easily into place. Subsequent expansion due to tightening up the gland will then give a good joint. Packing of this kind is especially valuable for rods which have a slight lateral motion, since the rubber center will hold the fiber cushion against the rod at all times.

The ring packing shown in Fig. 7 is intended for high steam pressures. It is composed of a rubber cushion lying next the stuffing-box wall, and a thick layer of asbestos cloth inside, the whole being encased in a cotton duck covering. The fibrous portion of the packing is saturated with lubricants to keep it pliable and to lessen the friction.

Fig. 8 illustrates a combination ring packing. The rubber expansion cushion is shown at *A*, and *B* is a facing of soft metal, around which is built up a covering of cotton fiber, *C*. The advantages claimed for this combination are great strength and durability.

The ring packings thus far described have been solid rings, made in practically one piece. There are, however, numerous diagonal ring packings, a representative type of this clsas being illustrated in Fig. 9. It will be seen at first glance that this ring has considerably greater depth than the ordinary solid ring. The upper portion, *A*, consists of braided flax, circular in form. This rests upon a wedge, *B*, composed of cotton fiber, which in turn rests against a similar wedge, *C*. The three pieces composing the ring are held in their proper relative positions by a covering of cotton duck. The two wedges, *B* and *C*,

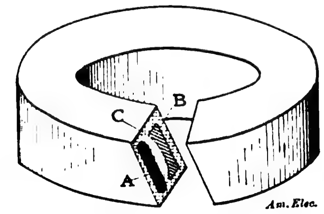

FIG. 8.

meeting along the inclined faces, tend to slide upon each other when the packing is compressed. Also, the circular section, *A*, is reduced, under the pressure of the gland, to an approximately rectangular form. The result is to force the inner surfaces of the wedge, *B*, and of the piston, *A*, against the

rod, the pressure against the rod becoming greater as the force tending to compress the packing increases.

This style of packing is designed to be self-setting. That is, it is intended to be adjusted by the steam pressure against

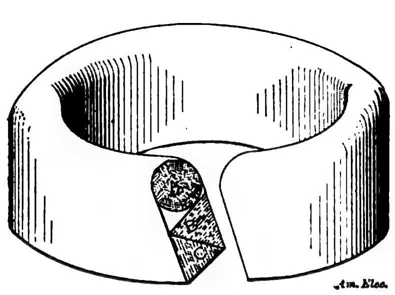

FIG. 9.

which the joint must be made tight. This means that the force with which the packing is held against the rod must vary with the varying pressure inside the cylinder, yet at all times be sufficient to prevent leakage of steam past the rod. With this style of packing any increase of pressure in the cylinder is at once transmitted to the bottom of the wedge, *B*, forcing the latter out against the rod. When, as at the end of the stroke, the steam pressure decreases, the natural elasticity of the materials causes the wedges to relieve some of the pressure on the rod. Since the friction on the rod depends upon the pressure against it, it is evident that there must be some saving by relieving the pressure at those intervals when the steam pressure is low. With the solid ring packings, the rings bear against the rod at all times with the maximum pressure required to hold the joint steam-tight, since the compression is furnished by the gland and not by the steam pressure.

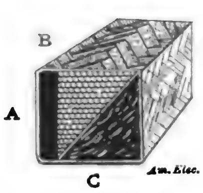

FIG. 10.

Another style of wedge packing is shown in Fig. 10. In this, *A* is a rubber cushion bearing against a wedge, *B*, made of cotton and rubber layers. The other wedge, C, is of soft flax, and it alone touches the rod. With this packing the gland is screwed up, and the expansion of the rubber sets the packing tight. It is claimed that this pack-

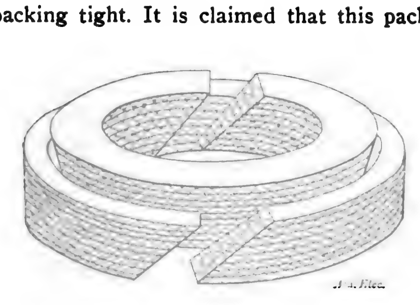

FIG. 11.

ing can be followed up until the greater part of the soft flax wedge is worn away before it becomes necessary to renew it.

Fig. 11 shows a sectional ring packing which is used to a considerable extent. It is composed of two rings, one within the other, meeting along a conical face, which makes the whole practically a wedge packing. The rings are constructed much like that shown in Fig. 5, and are lubricated with oil and graphite. Indeed, graphite is used in the composition of a large number of packings. It has the advantage of being able to fill up the slight depressions in a rod so as to present a smooth surface, while its inherent lubricating qualities are generally recognized. It is a lubricant, furthermore, which does not bake, volatilize or burn.

A sleeve packing is shown in section in Fig. 12. It is composed of alternate rings of flax packing, *A*, and cotton packing, *B*, backed by rubber, as at *C*.

In packing a stuffing-box, the box should be filled to about three-fourths its depth, each ring being pressed down snugly upon its neighbor. Then the gland should be screwed down only as tight as can be done with the fingers. Upon starting the engine,

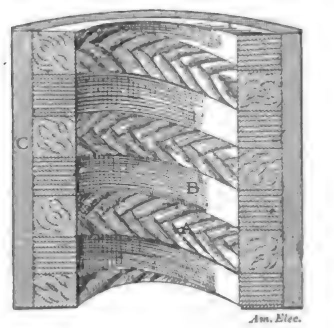

FIG. 12.

the heat of the steam will cause the packing to expand. The gland should then be loosened until steam blows through, after which it should be set up only to the point at which leakage ceases.

Failure to obtain or to maintain a leakless joint should not be taken as a sign of fault in the packing used. There are many conditions which may prevent the attainment of the desired ends, and those which exist in any given case may be due to the engine or to the engineer. If the piston rod is worn out of true, so that its section is other than circular, it will be found difficult to maintain a tight joint, because the packing will not be able to hug the rod at all points. If the piston rod is bent, the same failure will occur, because there will be a tendency for the rod to move away from the packing rings at certain points of the stroke. Again, if the piston is not properly centered, so that the piston rod fails to move in a straight line coincident with the cylinder axis, it will be found difficult to prevent leakage.

If the packing is too narrow for the stuffing-box, leakage will be a natural consequence, for only a few of the rings will touch the rod, and then only at a few points instead of entirely around the rod. The rings must fit snugly to both the rod and the wall of the stuffing-box. Furthermore, the packing should be suited to the conditions under which it is to be used. A packing for low-pressure steam should not be expected to give satisfaction with high-pressure or superheated steam. Cutting the packing rings either too short or too long may account for failure to obtain tight boxes. If the ends overlap, there will be unequal compression at various points in the stuffing-box, with liability to leakage where the pressure is least. Again, the gland may be screwed up unevenly so as to put greater pressure on one side than on the other. Or, as the packing wears away, neglect to follow it up so as to keep the rings in contact with the rod may account for poor results. These are manifestly points which cannot be charged up against the packing itself.

HIGH VOLTAGE POWER TRANSMISSION.

BY CLARENCE P. FOWLER.

The commercial feasibility with which power can be economically transmitted from any one point to any other point depends broadly upon the intervening distance. Whether this distance is within the economical transmission radius of the source of power will depend largely on the difference between the price which can be obtained for delivered power as compared with the cost of producing it. This difference must cover the cost of operating, the price of energy lost in transmission, the cost of maintenance and repairs, the interest on the investment and finally the dividends payable on the stock.

It is well known that the greater the output of all generating and transforming apparatus (within certain limits) the less will be the cost per kilowatt and therefore the less will be the interest charge per kilowatt on the investment, and as the operating force need not be materially larger for the greater output it follows that as the output is increased the operating expenses per kilowatt will be diminished also.

Both of these facts have the same significance, namely, that the larger the output of a plant that can be concentrated at one point, the greater will be the economy in the generation of electrical energy. Moreover, the larger the market that exists or that can be created at the point to which power is to be transmitted, the greater may be the distance between this point and the generating source for the reason that a greater margin will be available for investment in transmission line, owing to the saving effected by the increased size of the generating plant.

The amount of material in the line conductors depends directly upon the amount of power transmitted, when the voltage line drop and transmission distance are fixed. In other words the cost per plant kilowatt for line conductors does not diminish with increasing output, as is the case with generating and transforming equipment. Consequently, for a given voltage, line drop and transmission distance, the cost of line conductors per kilowatt transmitted will be practically the same for all amounts of power.

Since for a given line voltage, drop and transmission distance, no gain may be expected in the cost of the line conductors per kilowatt transmitted no matter what amount of power may be transmitted, and

as there appears to be a marked gain in operating expenses as well as in the interest charge on the investment per kilowatt of the generating and transforming equipment for large outputs, the transmission of power over any great distance will be commercially possible only when the market for power at the receiving end is large enough to permit such decrease in the cost per kilowatt of generating equipment as to more than offset an otherwwise prohibitive investment in transmission line.

Having taken into account some of the general economical aspects of the problem there remain some details to be considered, such as the selection of the line voltage; the arrangement and distance between line conductors; high-tension insulators, and the pole line.

Selection of Line Voltage.—Current practice seems to indicate the use of about 1,000 volts per mile of transmission, in order that the size of the line conductors may be kept within reasonable limits, but in some extreme cases two miles per thousand volts is allowed. In the matter of the selection of the proper line voltage, it is conceivable that the same may be raised to such a point that the excessive costs of transformers and line insulators will overbalance the saving effected by the reduction in size of the line conductors. The line voltage is also limited to a certain extent by losses which occur between wire and wire through the atmosphere and which experimental data have shown to be excessive after a critical voltage is reached. The losses below the critical voltage are trivial and have been proven to take place chiefly over the insulator surfaces and cross-arms. This loss is also affected to some extent by the diameter of the line wire—the smaller the wire the greater the loss which occurs with a given voltage. This seems to follow the well-known tendency of all high-potential discharges to jump or leak more freely between sharp edges and points than between rounded surfaces. In this connection the aluminum conductor (owing to its greater cross-section as compared with copper for the same conductively) would seem to present some advantage.

Arrangement of Line Conductors.—Owing to the economy in copper which the three-phase system offers it is presumed that this would be the only system considered in power transmission over any considerable distance. As to the arrangement of the three conductors, the best results are secured by locating the centres of these at the three points of an equilateral triangle, as this relation gives the least inductive reaction.

If a telephone circuit traverses the same pole line as the high-tension circuit, the former should be spiraled at intervals so that each wire of the high-tension circuit bears the same relation to the wires composing the telephone circuit in order to annul the effects of induction.

An important factor in the choice of the distance between different wires of a high-voltage transmission line is the atmospheric loss at the working voltage employed. Furthermore it is necessary to separate the line wire by such a distance that should a short-circuit be accidentally established it would not be possible for it to hold after the cause had been burned free. In this connection it must be borne in mind that an arc already established between line wires can be maintained by a much lower voltage than that required to start the arc. The best practice in this particular is to employ a separation of line conductors of about 1½ inches for each 1,000 effective volts.

High-Tension Insulators.—There are now several reliable makes of high-tension insulators on the market which are capable of taking care of working pressures up to 50,000 and 60,000 volts. There seems to be considerable difference of opinion as to whether glass or porcelain can be most advantageously employed for these higher potentials. Some of the advantages of glass insulators are: detection of a large proportion of the number of flaws by inspection; great dielectric strength; usually a somewhat more homogeneous structure than porcelain; less conspicuousness as targets on the cross-arms. The disadvantages of glass are its rather poor weathering properties and inferior mechanical strength.

The advantages of porcelain insulators are superior mechanical strength; somewhat better weathering qualities than those of glass; good dielectric strength when carefully vitrified. The disadvantages are that elaborate tests are necessary to discover flaws and the insulator forms a rather attractive target for mischievous persons.

Porcelain insulators seem to be gaining in favor owing to improvements in the methods of manufacture. In the production of these insulators for high potentials, the great difficulty encountered heretofore was to produce an insulator of sufficient size in which the porcelain was homogeneous throughout. This trouble has been overcome by making insulators in as many as three distinct parts, these elements fitting inside one another when assembled and being held together by Portland cement, forming a composite insulator of porcelain of uniform density throughout and of sufficient size to possess the necessary surface leakage dimensions for the working voltage which it is intended to withstand.

In short, whether the insulator be glass or porcelain, it should have dielectric strength sufficient to prevent the current from leaking directly through the material of which it is composed and its dimensions should be large enough to prevent appreciable leakage of current over its surface.

Pole Line.—Where the amount of power transmitted is considerable and, therefore, reliability of service is of paramount importance, there seems to be a growing tendency toward abandonment of the wooden pole construction in favor of the more substantial steel towers. With increasing voltages it has also been found advisable to construct duplicate transmission lines on separate towers spaced from 30 to 50 feet apart.

These steel towers are usually constructed of angle iron riveted together in such a manner as to form a rigid structure in the form of a pyramid, the base of which is securely fastened to a substantial foundation. The towers are usually spaced so that there are from 12 to 15 per mile as contrasted with the usual hundred-foot spacing commonly used with wooden-pole construction.

Inasmuch as there are required only about one-fourth as many steel towers as wooden poles per mile of transmission, there is only one-fourth the number of insulating points to give trouble along the line when the tower construction is used. To effect this advantage the insulator has to possess high dielectric strength for the reason that the use of metal pins brings the ground potential up inside the bell, which would not be true in the case of an insulator supported on a paraffin-treated, hard-wood pin. Moreover, since the spans are longer the insulator also has to sustain a greater mechanical strain. It is therefore evident that the use of the steel tower for long-distance transmission has been largely dependent upon the evolution of a high-tension insulator possessing the proper electrical and mechanical qualities.

The chief disadvantage of the steel-tower construction is its high initial cost, but when reliability is considered the installation cost should not prove any great barrier to its use.

When the route of a transmission line presents a rather wavy profile, as in the case of mountainous country, it is usually thought to be good practice not to follow the slopes of the land closely, but by the use of short and long towers, or poles, as the case may be, the wires may be run on smooth grade and thus avoid undue mechanical strains on the insulators and pins. In passing over a summit, the top may be rounded off by the use of relatively long poles on either side of the pole on the crest of the hill, and in this manner distributing the compression strains among several insulators, instead of confining these locally to the crest insulator, as would be the case were the line allowed to follow the natural slope of the land. Furthermore, by utilizing relatively tall poles in the valley the depression may be reduced with consequent advantagous division and reduction of the tension strain on the insulators. This feature assumes importance where composite insulators are employed; as the elements of which these are composed may be in danger of being separated by undue upward strain. The foregoing are some of the features, briefly stated, that command attention in connection with the lay-out of a high-tension transmission system.

International Association of Municipal Electricians.—At the tenth annual meeting of this association, held August 23, 24 and 25 at Erie, Pa., several papers of practical merit were read. Among these may be mentioned one by Capt. William Brophy, of Boston, on "Suggested Improvements in Fire Alarm Telegraph Systems," one by Mr. Louis Gascoigne, of Detroit, Mich., on "Underground Construction," and one by Mr. H. R. Allensworth, of Columbus, O., on "Electrostatic Effects in Telephone and Telegraph Circuits."

The Electrical Equipment of the American Thread Company

BY GEO. A. BURNHAM.

The hydro-electric plant of the Willimantic Mills of the American Thread Co. presents several unusual and interesting

FIG. 1.—DAM ACROSS THE WILLIMANTIC RIVER.

features in its electrical equipment. The plant is situated on the banks of the Willimantic River, from which a portion of the power consumed is taken. The flow of water is comparatively swift and varies within wide limits during the different seasons of the year.

The intakes to the water-wheels are from three different dams located about 500 feet apart. These dams are of solid stone masonry, and the material for construction was blasted from the river bed.

The available horse-power of dam No. 1 is 950 horse-power ten months in the year and 350 horse-power twelve months in the year. The water from this dam is diverted into a canal 17 feet wide, 10 feet deep and about 600 feet long, from which it passes through an 800-h.p. horizontal turbine and

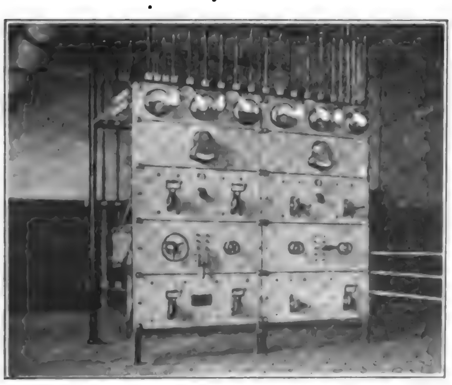

FIG. 2.—SWITCHBOARD.

is discharged through the tail race in the river below dam No. 1.

The water which is utilized in the 800-h.p. turbine, together with that which flows over dam No. 1, is backed by dam No. 2, of which the available power is 300 horse-power twelve months in the year and about 350 horse-power ten months in the year. The water diverted by this dam is passed through three 250-h.p. vertical turbines and discharged into the river below, to be again utilized by two 75-h.p. vertical turbines located at dam No. 3.

The average total available water-power is about 1100 horse-power yearly. The total power consumed is about 3000 horse-power, of which 1100 horse-power is derived from water and the remainder is furnished by steam. A view of dam No. 2 and a portion of mill No. 2 is shown in Fig. 1.

Although contrary to modern practice, the generating units, instead of being grouped in one central station, are spread out through the various mills, and in each case driven from the main shaft or the water turbines. This arrangement gives a very flexible and reliable system; also provides a way to utilize the surplus water, which would otherwise have been wasted over the "spillway," by converting it into electrical energy and transmitting it to the mills which are operated by steam.

The electrical equipment throughout was manufactured by the Stanley-G. I. Electric Manufacturing Company, of Pittsfield, Mass. The generators and synchronous motors are all of the inductor type, two-phase, 60-cycle, and operate at 2,350 volts.

The main station is located at mill No. 2 and contains a 300-kw. and a 100-kw. alternator, the fields of which are excited by two 125-volt, direct-current generators of 9 kw. and 7 kw capacity; a 45-light Brush arc machine, with its plug-board, and the main distributing board from which all circuits are controlled and to which all feeders from the outlying stations are connected.

The switchboard consists of two panels of blue Vermont marble, seven and one-half feet high, two inches thick, mounted on heavy steel angle bars. The panels are "built up" of five sub-panels each four feet long and eighteen inches wide. On the back of the board are supported two sets of bus-bars, one connected to the 300-kw. machine and the other to the feeder of all the other stations, and also to the 100-kw. machine located in the main plant. Four switches at the base of the board control the entire output of the plant. Two sub-panels carry the field switches and also the field and exciter rheostats. The field switches are of the double-pole, double-throw type, which enables either of the two exciters to be used to excite either of the fields of the two generators.

One panel supports the two main switches which connect the 300-kw. machine to its bus-bars, and another supports two switches which were originally designed for main switches of the 100-kw. machine, but are now used to tie the feeders of the outlying stations to the feeders of the 100-kw. generator located in the main plant. These two sets of switches are of the combination-slide switch and circuit-breaker type. Two static ground detectors and two voltmeter switches, by means of which the voltmeters may be connected to either phase of the system, are mounted on a panel, on which are also located the synchronizing lamps and plugs.

The top panel is somewhat narrower than the others and carries the measuring instruments, whose dials are illuminated by four double-armed pilot lamps. On the adjacent panel are located two ammeters and a voltmeter. A duplicate set is also provided on the other panel. These instruments indicate the total output of the station. The board as a whole presents a very neat appearance, being very compact and yet having ample room for the proper spacing of the wires. Fig. 2A is a diagram of the switchboard wiring, while Fig. 3 shows a diagram of connection for the feeders from the out-

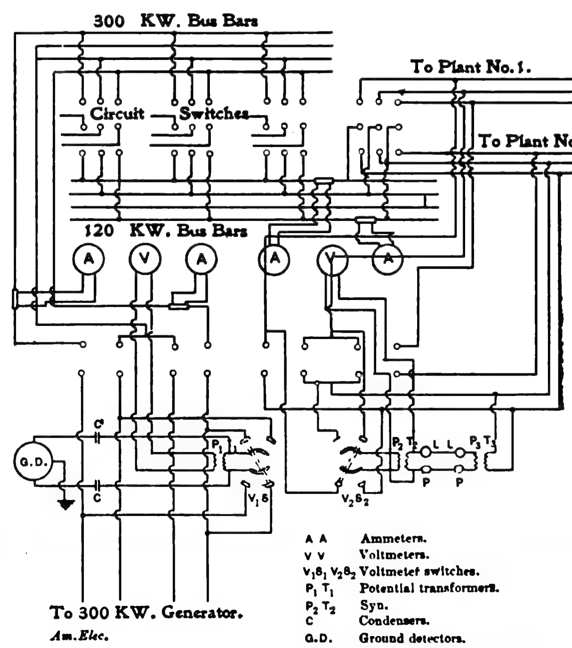

FIG. 2A.—DIAGRAM OF SWITCHBOARD CONNECTIONS.

lying stations and the switching apparatus on the main switchboard.

Plant No. 1 is located at mill No. 1 and contains a 100-kw. alternator and a 2-kw., 125-volt, direct-current generator used as an exciter. The switchboard is of the skeleton

type and is equipped with circuit-breakers, two ammeters, static ground detector, power factor indicator and the usual synchronizing appliances. Fig. 4 shows the generating outfit. This machine is used through the

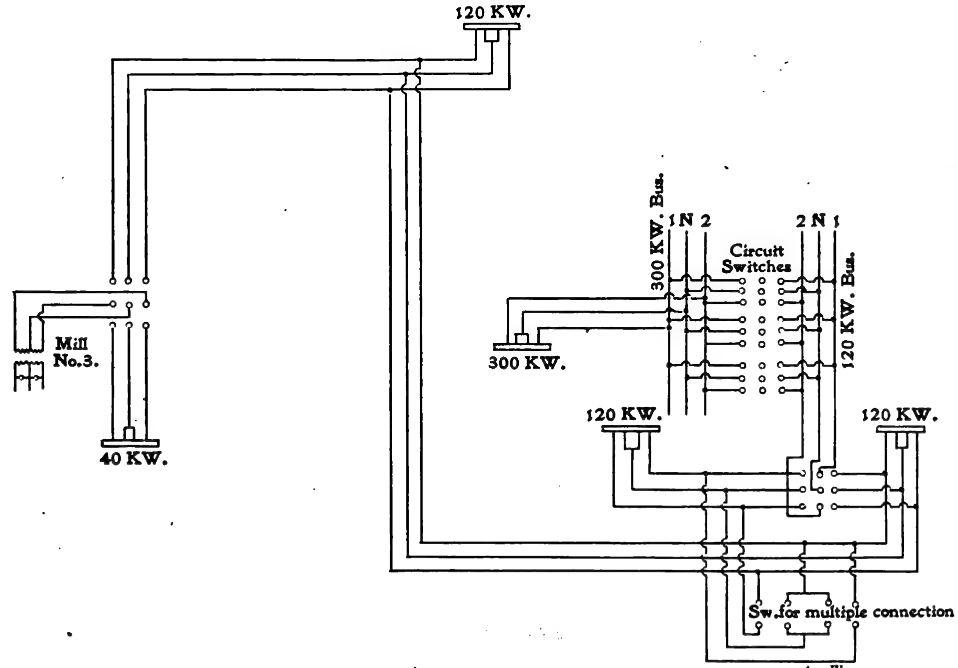

FIG. 3.—DIAGRAM OF CONNECTIONS FOR FEEDERS FROM OUTLYING STATIONS.

day to transmit power to the steam-driven mills, and during low water is used as a synchronous motor, taking current from the generators below the No. 2 dam or the steam-driven units.

Plant No. 3 is located at mill No. 3 and consists of a 40-kw. generator and an exciter of 1½-kw. capacity. This machine is driven by water-power and is used exclusively for lighting, but may be thrown in parallel with the whole system.

Plant No. 4 is located at mill No. 4, and

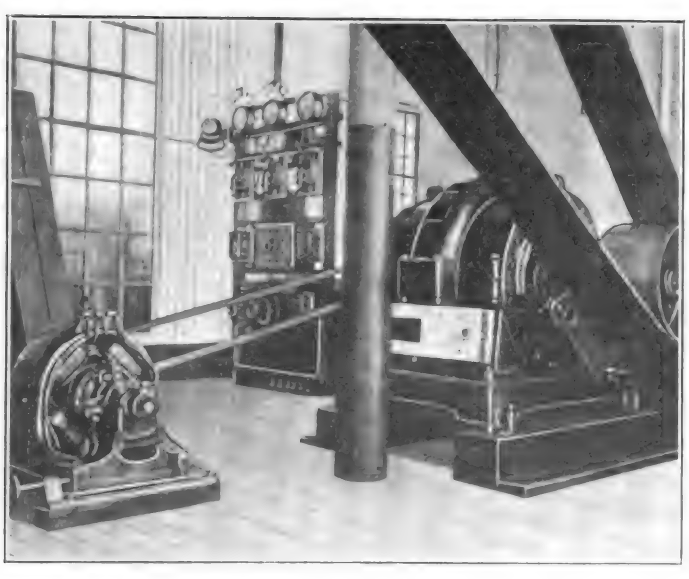

FIG. 4.—ELECTRIC GENERATING OUTFIT IN MILL NO. 1.

the generator, which is a 120-kw. machine, is driven from the main jack-shaft of the mill. The field of this machine is excited by a 2.62-kw., 125-volt, direct-current generator. The switchboard is of the skeleton type and is a duplicate of the board at mill No. 1, with the exception of the power factor indicator. This plant is steam-driven and is only operated during dry season to help out the other mills; at other times this generator is used as a synchronous motor, current being taken from the water-driven plants.

The building of a pole line to support the conductors from the various mills was a rather serious problem. The character of the soil about the mills is very rocky and in most cases solid ledge, making the construction of an ordinary pole line out of the question. This naturally resulted in placing the wires on the mills; but this has also entailed other difficulties owing to snowslides and dropping icicles, which formed in abundance during the winter months. The difficulties were overcome by several simple protective devices. The cross arms were made of 6-in. channel irons. The pins were also made of iron and bolted to the face of the channel irons, which were attached to the stone buildings by means of expansion bolts. Fig. 5 shows the method of attaching the pin to the arm. Insulators tested to 5,000 volts were used throughout the line construction. This method provides a very rigid support for the wires, and no trouble has been experienced with the arrangement.

The transformers are of Westinghouse, Stanley-G. I. and General Electric makes of the following sizes: Three 40-kw., two 25-kw., six 15-kw., five 10-kw., and several others of smaller sizes. The primaries of these transformers are connected to the middle and outer wires of a three-wire, two-phase system, and are arranged in such a manner that the load at all times is nearly balanced. Fig. 6 shows a view of one of the 40-kw. transformers, installed on the roof of mill No. 4. The secondaries of these transformers are connected to the three-wire distribution which is used throughout the mills.

Forty Couch & Seeley inter-communi-

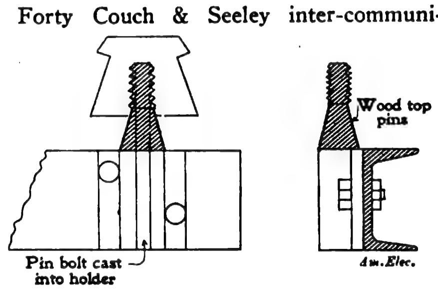

FIG. 5.—METHOD OF ATTACHING PIN TO ARM.

cating telephones are installed in the mills, in addition to several other private lines. The cables are of the paper insulated type, enclosed in a lead sheath. Branches from the main cable are all made from junction boxes, by means of which the system may be divided into six separate systems. This division makes the locating of cable trouble very easy.

The engine and water-wheel rooms are all equipped with emergency stop signals, and a separate system is installed for start-

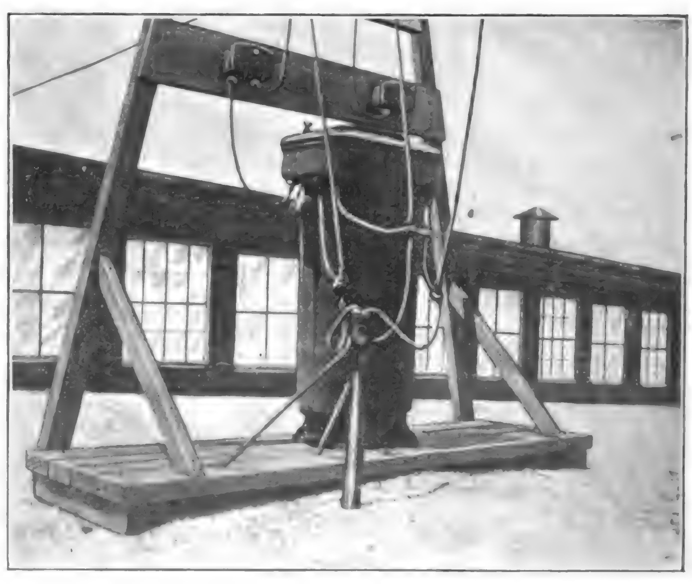

FIG. 6.—TRANSFORMER ARRANGEMENT ON ROOF.

ing and stopping. The watchman's clock system is of the battery type and consists of about two hundred stations. The signals are recorded on a four-dial clock situated in the main office. The system of electrical distribution was designed and installed by the writer.

ALTERNATING-CURRENT ELECTROMAGNETS

BY CHARLES R. UNDERHILL.

The constantly increasing use of alternating current for power as well as for lighting purposes has created a demand for electromagnets which will operate with alternating current, and since in other branches of electrical engineering direct-current apparatus has been successfully duplicated for alternating-current circuits, so may electromagnets also be made to operate on alternating currents, although more factors have to be considered in their calculation and design.

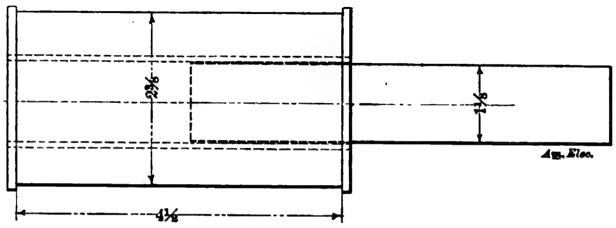

FIG. 1.—SOLENOID USED IN TEST.

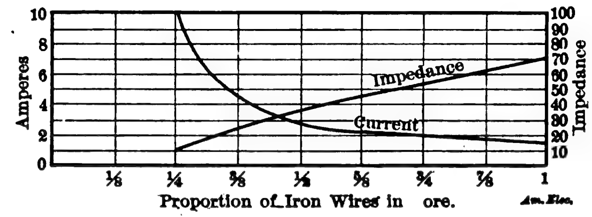

FIG. 5.—EFFECT DUE TO VARYING IRON IN CORE.

The laws governing the pull, range and heating of direct-current electromagnets are now generally known, so that the design is comparatively easy, but while the general laws of direct-current electromagnets must be followed in calculating alternating-current electromagnets, the extra factors mentioned entirely change the characteristics.

The first new factor with which we have to deal in designing an alternating-current electromagnet is inductance, which produces an effect which is the same as the counter e.m.f. in direct-current motors. Therefore, while the current is constant throughout the entire range of a direct-current electromagnet, the current will change at every point throughout the entire range of the alternating-current electromagnet ,and moreover this changes with the frequency.

It is evident that for the same line voltage, the alternating-current electromagnet will require much more current than the direct-current electromagnet, since the actual working voltage is greatly reduced in the former, owing to the counter e.m.f. of inductance. Therefore there will be fewer turns in the alternating-current electromagnet but more current than in the direct-current, in order to produce the same ampere-turns. At first though it would seem that this increased current would tend to overheat the winding, but when it is considered that the actual working voltage is much less than the line voltage on account of the inductance, it is obvious that the heating will be about the same for both electromagnets, although the winding on the alternating-current electromagnet will produce more ampere-turns for the same energy in watts than the direct-current winding, owing to the greater percentage of copper in the former winding. The fact that the alternating-current winding requires more current, and consequently a much coarser wire than the direct-current winding, also tends to reduce the cost of the wire and the cost of winding, but this is counterbalanced by the cost of the iron or steel portion of the electromagnet, which has to be laminated, whereas in the direct-current electromagnet it may be, and usually is, solid.

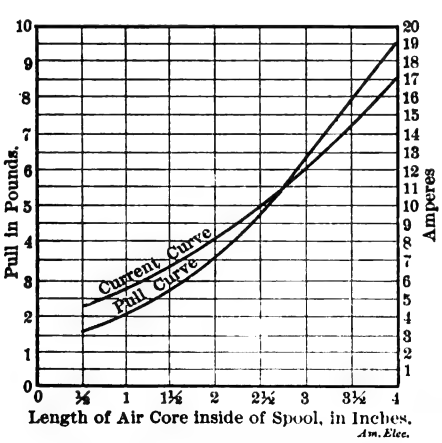

FIG. 2.—TEST OF SOLENOID IN FIG. I.

In order to show the effects due to inductance, some actual tests will be cited. The solenoid in Fig. 1 was tested with a core or plunger consisting of a bundle of soft iron wires, and Fig. 2 shows the result of a test of this solenoid on a 104-volt 60-cycle circuit. It will be noticed that as the iron is withdrawn, the current increases, thereby increasing the ampere-turns, and consequently the pull on the plunger.

The coil in Fig. 3 has a laminated core, and also three taps, making four test windings. The resistances were 0.11, 0.23, 0.36 and 0.63 ohm respectively, and the turns 131, 261, 388 and 609 respectively. Fig. 4 shows the resistance and turns and the corresponding current on 104 volts at 60 cycles. This also shows the ratio between resistance and impedance for different numbers of turns. The curve in Fig. 5 is plotted from a test of the entire winding of 609 turns and 0.63 ohm, and shows the effect of inserting different proportions of the total amount of the iron wires constituting the core, which was 7½ inches long.

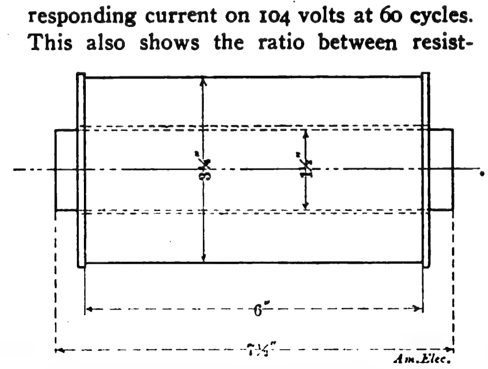

FIG. 3.—DETAILS OF INDUCTANCE COIL WITH TAPS.

The test plotted in Fig. 4 shows that while the resistance in the winding was only 0.63 ohm, the total impedance was 104 ÷ 1.5 = 69.4 ohms, making the resistance of the copper in the winding practically a neglible factor when the 609 turns were in circuit, but the resistance of the copper becomes important when fewer turns are used, as when they are reduced to 131 in this case. This test also shows that the impedance varies approximately as the quare of the number of turns when the resistance is low, and consequently the current varies (approximately) inversely as the square of the number of turns.

In order to prevent eddy currents, the ferric portions of alternating-current electromagnets are made of thin laminae insulated from one another. These should also be very soft so as to keep the hysteresis as low as possible. For this reason alternating-current electromagnet cores are usually operated at lower magnetic densities than direct-current electromagnets. Stampings from transformer iron or steel are suitable for this purpose, and when riveted together make firm frames and armatures. This method of construction naturally makes the cores of squares or rectangular cross-section.

The spools for alternating-current electromagnets are usually made of brass, slotted in the direction of the lines of force in order to prevent induced currents from being established in the brass, which would cause a considerable energy loss as well as overheating the spool and winding.

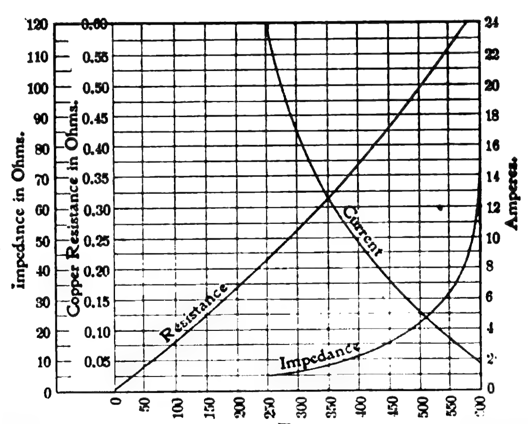

FIG. 4.—CHARACTERISTICS OF INDUCTANCE COIL WITH TAPS.

While the single-coil type of iron-clad solenoid or plunger electromagnet (Fig. 6) presents no serious difficulty in design when punches and dies are made, the two-coil type shown in Fig. 7, made from U-shaped laminations, is more easily constructed, although there are two spools. In this case the armature consists of one of the U's, and the stops are formed by the other. The

rest of the construction is obvious. By mounting shorter spools upon the U-shaped pieces, very good horseshoe electromagnets for alternating-current work are obtained.

Fig. 8 shows the result of a test of the two-coil electromagnet shown in Fig. 7. This test was made with 104 volts at 60 cycles, the spools being connected in multiple across the supply circuit. Each spool contained 1,400 turns of wire. The fact of the current rising tends to keep the curve up, whereas if the current were constant, as

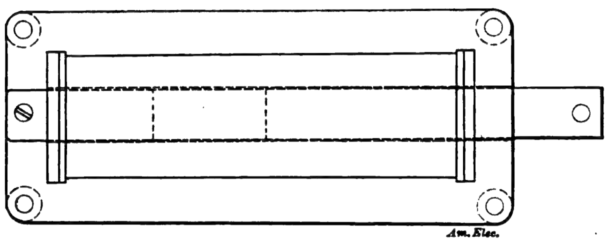

FIG. 6.—SINGLE-COIL TYPE OF ALTERNATING-CURRENT PLUNGER ELECTROMAGNET.

in a direct-current electromagnet, the pull would fall off much sooner near the end of the coil. On the other hand the maximum pull would be much higher if the current were constant, at say 6 amperes. If it were not for the fact that the coils are half full of iron when the plungers are all the way out, the current curve would not bend over as it does in Fig. 8, but would bend upward.

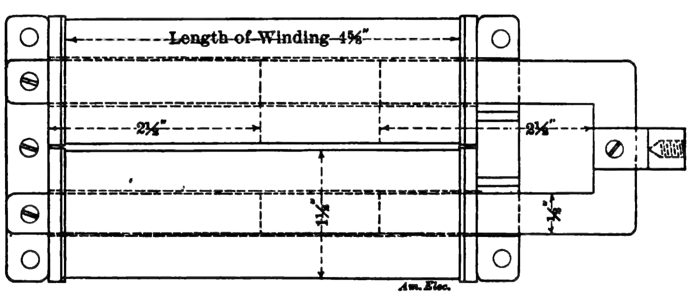

FIG. 7.—TWO-COIL ALTERNATING-CURRENT ELECTROMAGNET.

This magnet is capable of a much stronger pull with correspondingly stronger current, but it was designed for continuous service, and therefore would overheat if the impedance were made lower. This objection may be overcome by switching in an

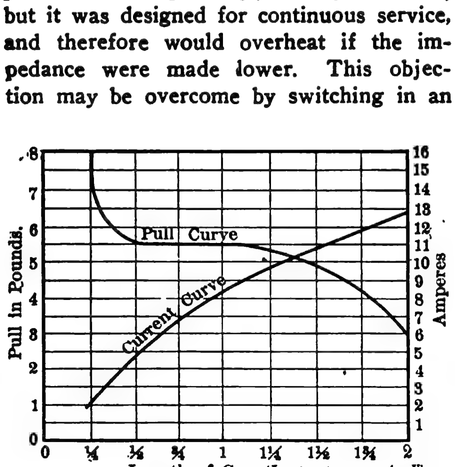

FIG. 8.—CHARACTERISTICS OF ALTERNATING-CURRENT, TWO-COIL, PLUNGER ELECTROMAGNET.

inductive coil at the end of the stroke of the armature, unless the electromagnet is operated too frequently.

For a longer range of action the stops or ends of the stationary U-shaped piece should be shortened so that they would only project a short distance into the winding, say ½ inch in this case. The effect for very long alternating-current iron-clad solenoids is an almost constant pull over a long range, but with an ever-changing strength of current. While the suddent inrush of current at the beginning of the stroke of an alternating-current electromagnet is objectionable in many cases, the small amount of current at the end of the stroke gives it an advantage over direct-current electromagnets where the current is to be left on after the work is completed, and makes the use of an automatic cutout with an inductive coil unnecessary. The alternating-current electromagnet of the type mentioned tends to take only what current it needs for a uniform pull.

Greater care must be exercised in alternating-current than in direct-current windings, for where the short-circuiting of a few turns of wire would do no appreciable harm in a direct-current electromagnet, the result would be disastrous in an alternating-current magnet.

Where the magnet is to be used on circuits of more than one phase, the magnet may be connected in one of the phases only, or magnets corresponding in number to the number of phases may be connected in the respective phases, with their armatures connected to a common bar or lever, as in Fig. 9.

In order to prevent the inrush of current at the beginning of the stroke, an inductive coil may be used as a compensating coil. This should be of comparatively low resistance and of few turns, so that while it would offer a high inductance when considerable current was flowing, the impedance would be small when the current was decreased as the iron plunger entered the coil of the electromagnet. This arrangement, of course, tends to reduce the pull at the start. One disadvantage of the alternating-current electromagnet is the disagreeable humming sound which is produced when the armature approaches the poles. This effect will also be noticed in other parts of the magnet when the laminations are not firmly fastened together.

AN AUTOMATIC BOILER FEED PUMP.

BY HENRY F. SCHMIDT.

It is strange that consulting engineers and designers of power plants have failed to appreciate the advantages and economy of using motor-driven or turbine-driven centrifugal pumps for boiler feeding, for, as will be shown below, they meet every condition perfectly and really present the ideal method of accomplishing this ex-

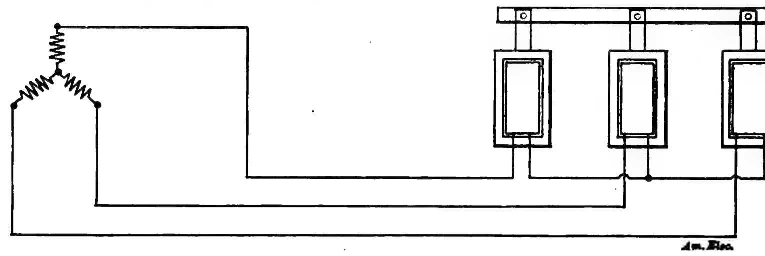

FIG. 9.—METHOD OF CONNECTING ALTERNATING-CURRENT ELECTROMAGNETS TO OPERATE ON THREE-PHASE CIRCUITS.

tremely important work.

The first point in favor of the centrifugal pump is that it has neither suction or discharge valves; the next is that it has but one moving part which has a continuous rotary motion and delivers the water in a constant stream, in contrast with the intermittent impulses of the common duplex pump generally employed for this class of service. The result of the latter feature is that there is no vibration of the pipes, which often causes no little trouble, and as the motion of the water is steady there is much less chance for scale to deposit in the feed pipes. Of course, it is almost unnecessary to point out the advantages accompanying a valveless pump and one in which there are no plungers to be packed, no steam valves to reseat and no pistons to require new rings from time to time.

Another point in favor of the centrifugal pump, and one which is really the most important, is that the pump, running at a constant speed, delivers water at a certain pressure which it cannot exceed by more than five or ten per cent., even though the delivery pipe be completely closed, which condition with a reciprocating pump would probably mean a broken pipe or pump. This characteristic makes it possible, if the boilers are fed by hand, for a fireman to shut off the feed to any boiler or to all of the boilers without having to leave it or them to shut off the pump, which is impracticable in many plants, where the pumps are located in a separate room. Moreover, it makes the automatic feeding of the boilers a very simple matter, as all that is required is a ball float for each boiler, controlling a balanced valve in the feed pipe. This makes it unnecessary to have a connection to the steam line supplying the pump, as the latter runs continuously, whether any of the boilers are being fed or not. This method of automatic feeding makes all the boilers independent of each other; it is not necessary that the water line in all the boilers shall be at the same level, as must be the case with all other types of automatic feeding devices. This

will be appreciated in plants which contain several sizes of boilers, or where some of the boilers are of the vertical type and some of the horizontal type, having their gauge glasses at widely different levels. The method of arranging the proposed automatic system is indicated partially by Fig. 1, which is intended merely to illustrate the principle.

To illustrate the economy incidental to the use of centrifugal pumps, let it be as-

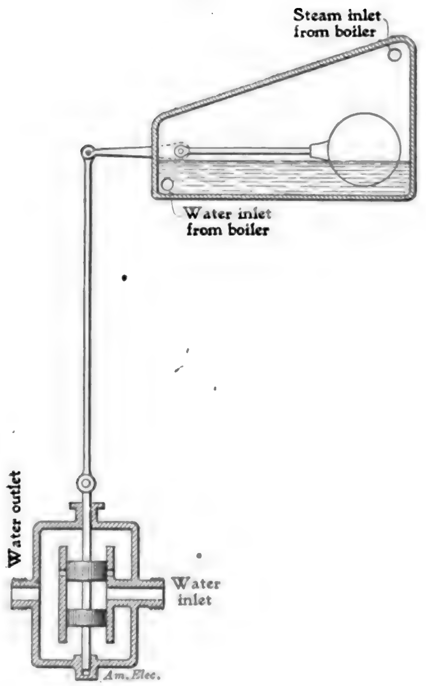

FIG. 1.—AUTOMATIC FEED-WATER SYSTEM.

sumed that the boiler pressure is about 150 lbs. per square inch, that a three-stage, direct-current, motor-driven pump is employed and that the motor receives current from a generator driven by a compound, non-condensing engine of about 200 kilowatts capacity. For this outfit, it is conservative to assume an efficiency of 55 per cent for the pump, 85 per cent for the motor, and a steam consumption of 40 lbs. per kilowatt-hour measured at the switchboard. On this basis the steam consumption of the feed pump would be 64.2 lb. per water horse-power per hour. Now, to favor the reciprocating pump, assume that a compound duplex pump is employed, the steam consumption of which under favorable conditions would not be below 70 lbs. per indicated horse-power and which under favorable circumstances might have an efficiency of 85 per cent. Under these conditions the consumption of steam would be 82.4 lbs. per water horse-power per hour, showing a saving of 18.2 lbs. per hour in favor of the centrifugal pump, though the assumptions made are a little more favorable for the duplex pump than for the centrifugal.

Besides the actual saving in steam obtained by the use of the centrifugal pump, there would be another large saving due to the difference in repairs, since the only parts to wear out on the centrifugal pump are the bearings, which can be renewed at small cost and replaced in a few minutes, while the duplex pump requires new valves and packing for the plungers and demands considerable attention in the way of adjustment and regulating the speed to meet the demand made upon it by the boilers; this attention is not required by the centrifugal pump. Had it been assumed that the plant was run condensing, the saving in favor of the centrifugal pump would have been still greater, for the engine driving the generator would use the vacuum to much greater advantage than the duplex pump.

It might be suggested that the efficiency of the centrifugal pump would be very low when supplying only a small portion of its full capacity, and would consume power when merely churning the water without delivering any, but this objection can be met with the fact that a steam pump causes steam waste even when it is not running, and as its steam consumption is also very much greater at part capacity, it is highly probable that under ordinary working conditions the saving of the centrifugal pump over the duplex pump would be just as great proportionately at part load as at full load.

Furthermore, as the centrifugal pump gives a steadier feed and can be more accurately regulated, the maximum capacity of a centrifugal pump to supply any given battery of boilers would not have to be so great as if a duplex pump were employed; therefore, the centrifugal pump would be operating nearer its point of maximum economy than the duplex pump, and would therefore give a better average efficiency. The centrifugal pump would be somewhat more expensive than the duplex, but the difference would soon be made up by the saving in fuel and in the cost of maintenance and repairs.

Abstracts from Foreign Contemporaries

A Lamp for Temporary Installations.—The London *Electrician* illustrates a new lamp for use on temporary installations, and particularly for illumination purposes. The cap of the lamp is designed to enable it to be connected directly to the cables or wires without the intermediary of a lamp-

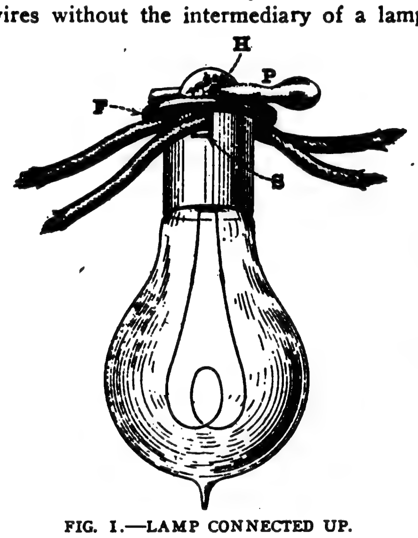

FIG. 1.—LAMP CONNECTED UP.

holder. The lamp cap is of china, and it has two grooves, in which spring contacts, *S S*, are fitted, as shown in Fig. 2. These two springs are separated by a china wall pierced with a hole, *H*. The two conductors are bared sufficiently to make contact with the top of the springs *S S*, and the fiber plate *F* is then passed over the china wall and is held in place by the wooden pin *P*. Fig. 1 shows the lamp connected up.

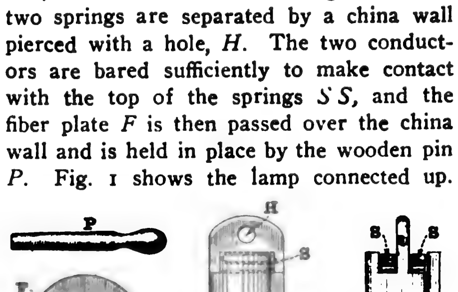

FIG. 2.—DETAILS OF LAMP CAP, FIBRE PLATE AND WOODEN PIN.

If, for temporary illumination purposes, it is desired to align the lamps accurately, thin slips of wood can be slotted to receive the china wall, and the lamp can then be fixed by placing the wooden pin through the hole.

The Aston "Worm Feed" Brush-Holder.—The brush holder illustrated herewith is described in a recent issue of the London *Electrical Review*. The holder shown is of the box type, and is arranged for rigid fixing to the brush pillar. In order to do this the tube of the holder is

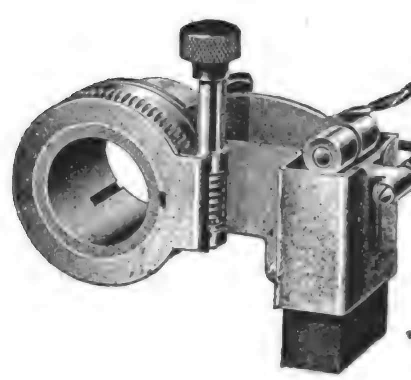

FIG. 3.—ASTON BRUSH HOLDER.

split through half its length, and an encircling clamping ring and key serve for tightening on to the pillar. The carbon brush is pressed down through the holder by two small rollers attached to the end of a lever pivoted on the brush pillar. The worm gear, also centered on the latter, when rotated by means of a thumb screw, exerts through a spring connection the requisite pressure on the lever and brush for the required adjustment. The lever is extended beyond the pressure rollers to provide a ready means of raising it, to try the tension or remove the carbon; its downward movement is confined to a slot, and it cannot touch the commutator. As the thumb screw is provided with an insulated knob, it can be safely adjusted while running.

Ignition Device for Gas and Oil Engines.—The arrangement for igniting and controlling the charge in internal combustion engines shown in Fig. 4 was described recently by the London *Engi-*

neer. The ignition chamber *A* is provided with a thread at its base to enable it to be screwed into the valve box, *B*. The valve seating of the valve *C* is turned in the valve box *B*, which is provided with four bosses; the boss *D* having an internal thread for the closing plug; the boss *E* having an external thread for screwing into the combustion chamber; the boss *F* forming the guide for the valve *C*, and to the outside of which is screwed the extended guide *G*; and the boss at the top into which the ignition chamber *B* is screwed. The port *H* in the valve box is open to the combustion chamber *Z*, and the port *I* to the ignition chamber *A*. *J J* are the vaporizer and air heater, and *K* is the vaporizer jacket. *L* is the engine admission valve; *M* is the half-speed shaft of the engine, to which is fixed the cam *N*. The lever *O*, the upper portion of which is shown broken off, is mounted on the fixed fulcrum pin *P*. The lower arm O_1 of the lever has suspended from it the link *Q*, which has a pin fixed at its lower end, on which are fitted two small rollers *R*, one on each side of the lever, which run on the face of the cam. *S* is the working piston and *T* the cylinder. When the piston returns, compressing the working charge drawn into the combustion chamber *Z* through the valve *L*, the compression pressure in *Z* lifts the valve *C* from its seat against the resistance of the spring C_2, and the chamber *A* fills with working charge. At a certain point in the compression stroke toward the end of it the small charge in the ignition chamber *A* is ignited. The pressure in *A* then becomes greater than that in the working cylinder, and consequently the valve *C* is kept tightly on its seat. On the dead point, or at the required lead before it, the cam *N* comes in contact with the rollers *R* on the suspended rod *Q*, and the latter then opens the valve *C* by pressure on the spindle end C_1. The ignited charge under pressure in the chamber *A* then flows rapidly into the working cylinder and ignites the main charge. The cam *N* continues to hold open the valve during two strokes, the working and exhaust strokes, and permits it to close at the end of the exhaust stroke. The pressure in the chamber *A* thus falls to approximately that in the working cylinder at the end of the exhaust stroke. To vary the time of ignition the lever *O* is shifted either by the governor or by hand.

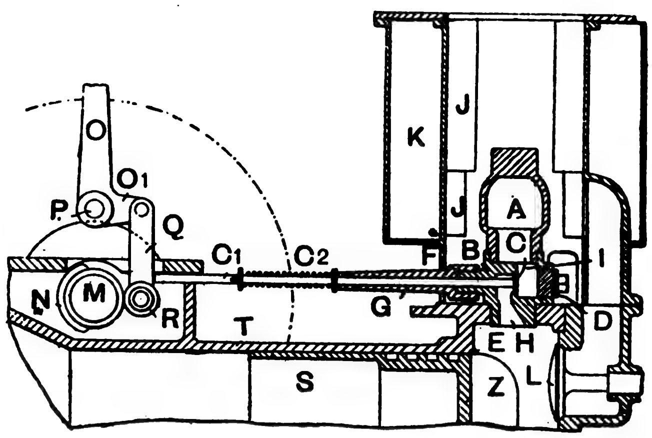

FIG. 4.—IGNITION DEVICE FOR GAS AND OIL ENGINES.

The Cyclone High-Speed Engine.—*Engineering* describes the small high-speed enclosed steam engine illustrated in Fig. 5. These engines have been specially designed to meet the demand for high-speed engines suitable for direct coupling to dynamos, fans, and similar machinery which have to run continuously for long periods without special attention. They are at present built in four sizes, the maximum speed of the three smaller sizes being 600 r.p.m., and of the larger size 450 r.p.m.. As will be seen from the illustration they are designed as compactly as possible consistent with accessibility, and their details follow the best high-speed practice. All parts are machined to jigs and gauges, so that they are interchangeable. The cylinders are tested hydraulically after machining to insure soundness of the casting, and are well lagged all over and clothed with planished steel. Piston valves are fitted, and are ground and lapped to fit the bore of the valve chest. They "float" on the spindles to find their own centres, and are not fitted with rings, except in the larger sizes when desired. The pistons are of forged steel, and the piston rods are accurately ground to size. The crossheads are made solid with the piston rods, and are fitted with adjustable cast-iron slippers turned when in position to the bore of the guides. Metallic packing is used in all stuffing boxes. The crank and eccentrics are cut from the solid, and the shaft is finished all over, the balancing of the rotating parts being done by weights cast in the fly-wheels. A throttling governor driven from the crank shaft maintains the speed with 1½ per cent. at all loads, with a momentary increase not exceeding 5 per cent. when full load is suddenly removed. It can be also regulated by hand when the engine is running. An oil-pump, driven from the eccentric strap, supplies forced lubrication to all moving parts, the crank pin and eccentric being fed through a hole in the crank-shaft from the main bearings, which are the main source of supply. These bearings are adjustable,

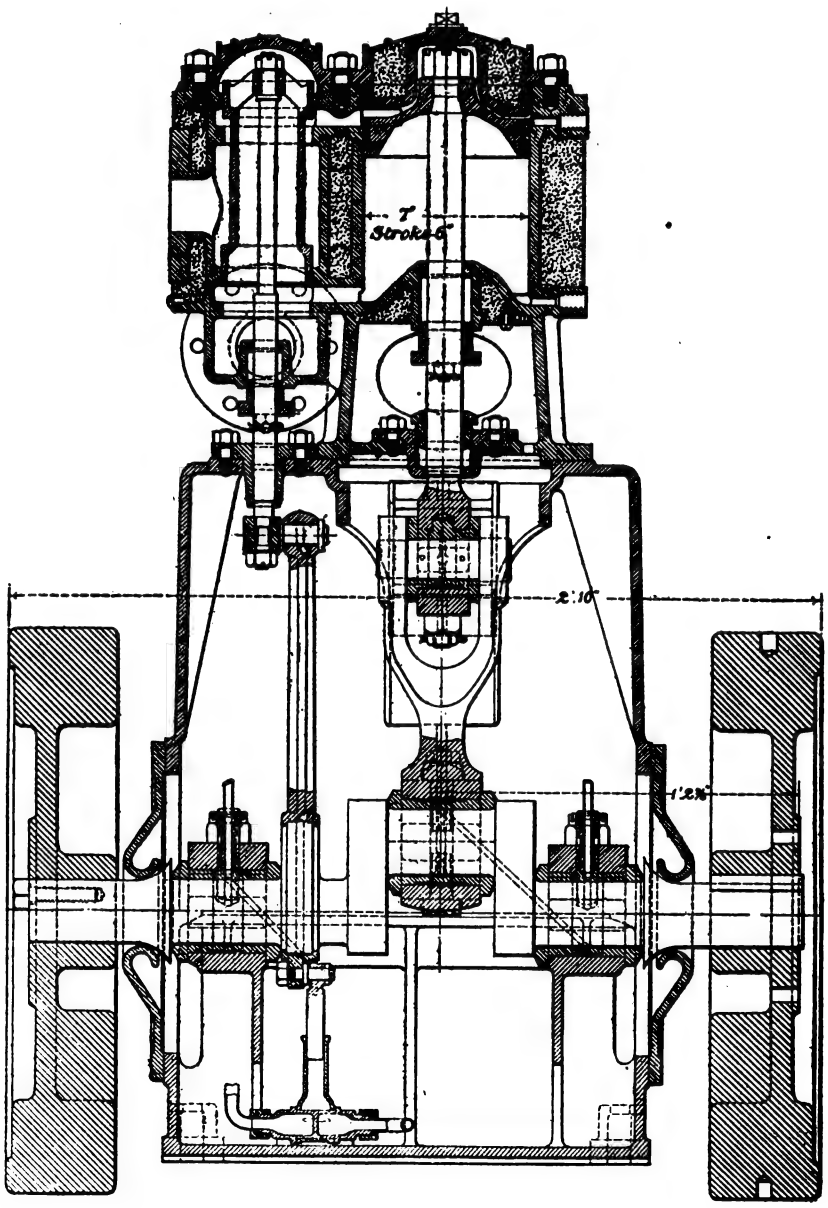

FIG. 5.—CYCLONE HIGH-SPEED ENGINE.

and can be removed and replaced without taking out the crank-shaft. A large door in the front of the casing provides access to the interior, a small door underneath being provided for getting at the oil-strainers, pump, etc. End doors outside the main bearings are moulded so as to prevent the escape of the oil thrown off by the oil-rings on the shaft, and all the interior of the casing is given two coats of a white enamel specially prepared to withstand the solvent action of hot mineral oils.

Modified Form of Schmidt Superheater.—Illustrated herewith is a modified form of the now well-known Schmidt superheater. In this design the superheater is provided with two steam chambers and with tubes closed at the end and having a partition to form two passages for the steam in each tube. The object of the partitions is to prevent the heat from one passage penetrating to the other. Referring to the illustrations, A is the superheater casing, B the cover, and C the tubes closed at one

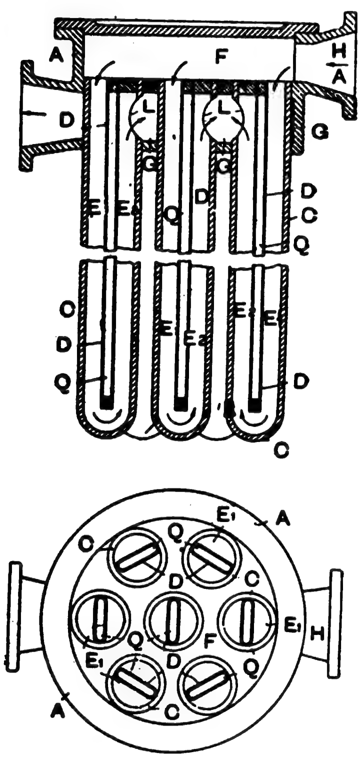

FIG. 6.—MODIFIED SCHMIDT SUPERHEATER.

end. D is a partition within the tube for dividing the interior of the tube into two spaces E_1 and E_2. The partition forms a casing Q and prevents the temperature of the steam passing along the space E_2 from being transferred to the steam passing through the space E_1. The hollow space of the casing Q is filled with heat non-conducting material. The apparatus operates as follows: The steam enters the chamber F through H, passes through the spaces E_1 and E_2 and leaves the tube at L, entering into the second chamber G; when passing the space E_1 the steam is heated by the influence of the burning gases surrounding the tube C and then the steam flows through the passage E_2 where it is further superheated by the influence of the gases surrounding the tube C. By the arrangement of the heat non-conducting partition Q the superheating is not disturbed by the steam passing the space E_1 which is not superheated to the same extent as the steam in the space E_2.

Storage Batteries and Their Electrolyte.—At a recent meeting of the Faraday Society, a paper was submitted by R. W. Vicarey, in which the author gave a résumé of observations and experiments referring to the deleterious effect of nitrogen compounds (especially ammonia) upon the durability, efficiency, and behavior of storage batteries. The paper deals with the action of ammonia and other nitrogen salts, and the salts of potassium, sodium, aluminium, magnesium, and calcium, and it discusses their uses in the various manufacturing processes. It also deals with the waters and acids used for the electrolytes of batteries. It would appear that ammonia must be considered as a dangerous impurity, the total absence of which, however, cannot be absolutely insisted upon. The presence of ammonia in the surroundings or neighborhood of the cell must be carefully guarded against, and the percentage actually present in the cell must be kept as low as possible by the use of waters and acids of the purest quality. The author points out that above certain limits of ammonia little difference is observed in the behavior of cells, but that below that limit much difference occurs. Thus, in experiments upon cells containing proportions of ammonia varying from 10 per cent. to 0.1 per cent. (7,040 to 70.4 grains per gallon), the loss in capacity was 22 to 31 per cent. immediately after the addition of the ammonia, while cells containing less than 0.1 per cent. did not drop in capacity immediately, but varied intermittently from 10 to 15 per cent, finally settling at the end of eight months to a permanent loss of 15 to 22 per cent. From the data given it appears that ammonia is very slow in its action before it makes any appreciable or apparent loss in the capacity of the cells, the average time being about 12 months, dating from the initial charge. The effects of ammonia in its various combinations appear principally in two distinct forms: (1) It causes an excessive disintegration or shedding of active material at the positive (PbO_2) plate; (2) it becomes deposited upon the negative (spongy) plate, and finally closes up the pores of the active material, thereby causing a decrease in the ampere-hour capacity or efficiency varying from 10 to 60 per cent in about 12 months. The use of water taken from the steam boiler and termed "distilled" is mentioned as a dangerous practice that is common in central stations.

Continuous-Feed Lubricator Fitted With Electric Alarm.—In the lubricator shown by Fig. 7, means are provided whereby an alarm is given when the oil vessel is full or empty, and when the lubricant is not passing properly to the part or parts to be lubricated. The arrangement, which is described in the *Mechanical Engineer*, comprises an oil vessel A adapted to contain liquid lubricant, and arranged to be connected with the part to be lubricated. The oil is supplied into the vessel A by a pump which is connected to a pipe C, above which is arranged a cock D, having a discharge pipe E. In the interior of the oil vessel is a float, suitably guided in its rising and falling movements. The guiding arrangement consists of a rod G passing through a hollow bridge piece H. At the upper side the float is connected by a pin I to a lever J, the opposite end of which is coupled to the plug of the cock D on the oil supply pipe C a further lever K being connected to the pin I of the float. This second lever is pivoted at L to a standard M carried by the upper portion of the oil vessel, and is one through which an electrical connection can be made through terminals M_1 and N wired to a battery or other source of electrical energy, in the circuit of which is also arranged an alarm or indicator adapted to act on the closing of the circuit. The second pivoted lever is adapted to complete an electrical connection at either end. For this purpose

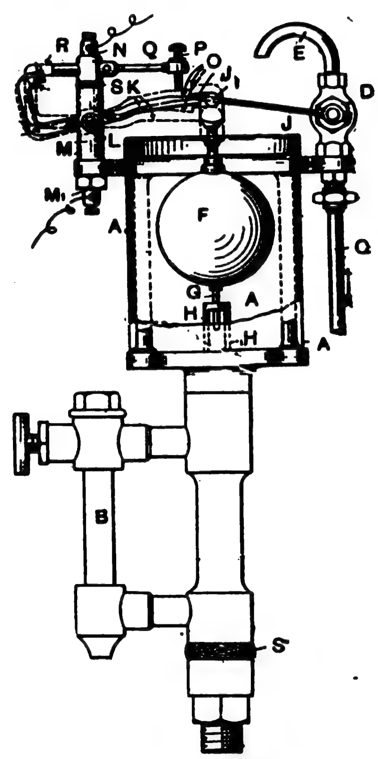

FIG. 7.—LUBRICATOR FITTED WITH ELECTRIC ALARM.

the inner end O of the lever may come into contact with an adjustable screw P carried by an arm Q projecting from the standard M when the oil vessel is full, thereby creating an alarm prior to the vessel overflowing, and at the same time indicating either that the oil supply is in excess of the feed to the part to be lubricated or that the feed pipe is stopped up. Simultaneously the float, by reason of its connection with the cock G, diminishes the oil supply or may be arranged to entirely stop it for the time being. On the other hand, the float may descend and increase the oil supply to the vessel A. In cases where there is not a continuous supply of oil, or, in fact, where such continuous supply is not sufficient for feed purposes, the float may descend and establish electrical connection by the other end R of the pivoted lever K

coming in contact with the standard M, and thereby indicating that the oil in the vessel A is running low. Again, where the feed is continuous the descent of the float may indicate that the oil supply from the pump or other general source of supply is stopped entirely.

Water Meter.—The *Engineer*, of London, describes the Leinert water meter, shown by Fig. 8 herewith. This apparatus is constructed somewhat on the principle of an automatic weigher. The water runs continuously to the meter, but is diverted by an automatic feed alternately to one or the other of two similar tanks. These tanks are balanced on knife edges in such a way that a certain weight of water will tilt the tank and at the same moment transfer the feed to the other tank. Each tank on tilting commences to empty through a syphon and returns empty to its original position in time to again receive water as the companion tank falls and tilts the feeder and

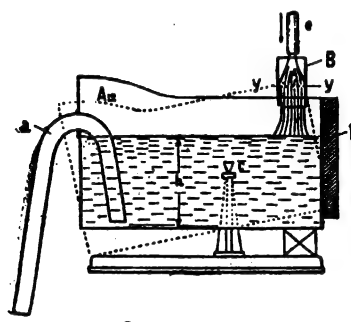

FIG. 8.—WATER METER.

recorder. The water is thereby measured by weight, and not volume, and the meter can thus deal with water of varying temperatures without impairing its accuracy.

Distributing Valve for Steam Engines.—The steam distributing valve shown in the accompanying engravings taken from the *Mechanical Engineer* is specially applicable to feed pumps and other engines adapted to work without the use of a crank shaft and connecting rod. Fig. 10 is a sectional elevation of a steam cylinder provided with the valve; Fig. 11 is a section through the valve box on the line 2—2, Fig. 10; and below is a sectional plan view of the valve box with the top cover removed. The steam cylinder A is provided with passages D and E, through which

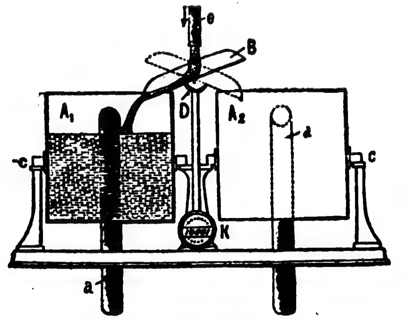

FIG. 9.—WATER METER.

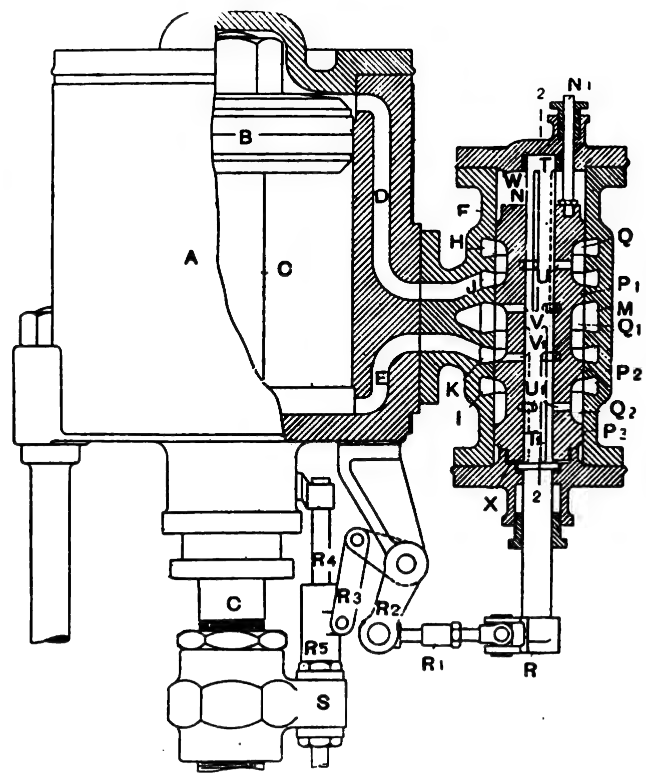
steam is admitted and exhausted alternately. F is the valve box, G being the steam inlet to the valve box, and H and I two annular spaces which are always in communication with the steam inlet G. J and K are annular spaces in the valve box which are always in communication with the passages D and E, and L is the exhaust outlet of the valve box constantly in communication with an annular passage M therein. The valve is made in two parts, which may be called respectively the main C. To enable the auxiliary valve to govern the movement of the main valve grooves T and T_1 are formed along the surface of the auxiliary valve O parallel to its axis. These grooves run the length of the part of the valve within the valve box, with the exception of a plain part in the center. In the two annular spaces Q and Q_2 formed in



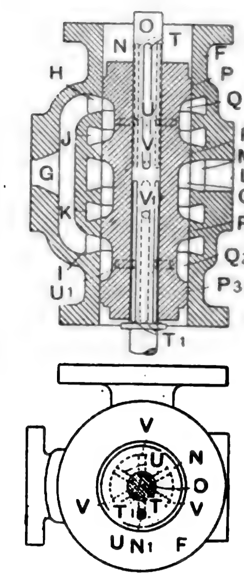


FIG. 10.—DISTRIBUTING VALVE FOR STEAM ENGINES.—FIG. 11.

and auxiliary slide valves. The main valve N performs the operation of distributing the steam to the two ends of the cylinder, and the auxiliary valve O governs the motion of the main valve, which is cylindrical and works in the valve box F. The main valve is prevented from rotating by the rod N_1, and has four cylindrical bearing surfaces. The two inner surfaces P_1 and P_2 serve to cover and uncover the passages J and K, and thereby the ports D and E to the cylinder during working, and so put the ends of the cylinder into communication with steam and exhaust in their proper sequence. The two outer surfaces P and P_3 of the main valve serve as pistons, and the space between them and the cover of the valve box is alternately put in communication with the steam and with the exhaust by the action of the auxiliary valve at the ends of the stroke of the piston, the main valve being thus caused to move from its one extreme position to the other. The auxiliary valve O is in the form of a cylindrical rod which passes through the center of the main valve N, and is rotated about its axis through a suitable angle, at or near the ends of the stroke of the piston, by the motion of the piston rod itself, through the medium of link mechanism. The mechanism comprises the link R_1, bell-crank lever R_2, link R_3, and a tappet rod R_4, to which rod are attached two tappets R_5, only one of which is shown. These tappets R_5 are actuated slightly before the end of each stroke by the striker S attached to the piston the main valve, and which are always in connection with the steam inlet, slots U and U_1 are cut respectively in the valve equal in width to the width of the groove in the auxiliary valve and of convenient length. These slots U and U_1 are so arranged that when those in the upper series, viz., U, are opposite the grooves T in the auxiliary valve, the lower series U_1 are opposite a plain part of the valve, and so are blanked. In the center annular space Q_1 formed between the two inner surfaces P_1 and P_2 of the main valve, which is always connected to the exhaust outlet L, slots or ports V and V_1 are also cut arranged in two rows, and so that if the upper row is opposite a groove in the auxiliary valve the lower row is blanked by the plain surface of the spindle and vice versa. The slots or ports U and U_1 serve to distribute steam to the ends of the main valve alternately, and the slots V and V_1 connect the ends of the main valve to the exhaust port alternately, whereby the main valve is made to move when the auxiliary valve or spindle is rotated about its axis.

Economy in Boiler Plant.—Although builders of boilers are presumably the persons most interested in building an efficient steam-raising plant, it must be remembered, says the London *Electrical Review*, that they are hampered by condition of competition arising from an improper understanding of the process of combustion and heat transmission on the part of prospective pur-

chasers. The paper read before the Institution of Electrical Engineers by Messrs. Booth and Kershaw pointed out that, for the proper combustion of bituminous coal, a large combustion chamber and the use of refractory surfaces is necessary. This, however, means increased cost of boiler setting, and the temptation is very strong to tender for and build a boiler which will generate its guaranteed steam per pound of coal, when, say, anthracite is used, independently of the consideration as to whether other coal can be economically brought to the locality of the boiler. In asking for tenders for boilers, therefore, the class of fuel to be used should be specified and a water evaporation guarantee on this basis asked for. Where such precautions are previously omitted losses in the steam raising plant are certain to ensue. Air will probably be admitted in excess above the grate to avoid smoke nuisance, bringing down the temperature of the furnace gases. Increasing the amount of air admitted increases the energy consumed in producing draft and the amount of heat carried off to the stack. An artifice to prevent the premature cooling of the gases by contact with water-cooled plates and tubes is the introduction into the furnace of refractory brick baffles. Where the combustion chamber is not sufficiently large to contain these refractory surfaces they are often interspersed among the tubes and flues. As, however, the gases have already become partially cooled, such devices can only be regarded as makeshifts to cover an initially bad design, and have, moreover, the effect of reducing the effective draft. Where it is found absolutely necessary for the avoidance of smoke nuisance to admit air above the grates, such air should be previously heated as much as possible to reduce the cooling of the combustion chamber as far as practicable. In some boilers steam is admitted below the fire grate. This device is useful where fuel giving intense local heat, such as anthracite or coke, is used, as the rapid deterioration of the furnace bars is avoided by the cooling action of the steam, and this steam, in passing through the bed of incandescent fuel, unites with the carbon to produce water gas. It is, however, a fallacy to suppose that the admission of steam above the grate aids combustion. The space above the fires should be exclusively reserved for the proper intermixing and ignition of air, oxygen, carbon or carbon-monoxide, and the energy absorbed in the dissociation of water will result in a net loss of heat. To obtain the greatest amount of steam per pound of coal from the boiler the maximum difference of temperature between the water and flue gases must be obtained at every point along the passage of the gases through the boiler. For this reason the hottest water should be found at the point where the gases first impinge on the heating surfaces, and the point of inlet of the feed water should be as near as possible to the point of exit of the gases to the main flue. Due recognition of the elementary principle that cold water is of higher specific gravity than hot will tend to better design from the point of view of circulation, and consequently better evaporating qualities.

CENTRAL STATION ENGINEERS.—XI.

F. W. Little.

The subject of the present sketch was born at Dixon, Ill., on August 26, 1859. He received a common school education and in 1881 removed to Sioux Falls, S. D., where he engaged in the banking business and through the purchase of gas and electric securities had his attention directed to these fields. In 1887 he removed to Sioux City, Iowa, where he continued the banking business and also continued to handle gas, electric, and street railway securities. In 1890 he became president of the Lincoln Street Railway Company of Lincoln, Neb., which company afterwards acquired all the horse-car lines in Lincoln and substituted electricity as the motive power. He remained in this position until 1895. In the fall of this year he migrated to Akron, Ohio, becoming vice-president and general manager of the Akron Gas Co. While at Akron he rebuilt and extended the manufacturing and distribution plant of the Akron Gas Co. In 1899 he removed to Peoria, Ill., where he was offered the position of vice-president and general manager of the Peoria Gas & Electric Company. Since his connection with the company it has acquired all the gas and electric properties in the city of Peoria.

F. W. LITTLE.

Municipal Plant Operation.

To the Editor, American Electrician:

On page 429 of your August number there is a note entitled "'Successful' Municipal Plant Operation," which reflects great discredit on the city lighting plant of this place.

Not to be contentious, I will admit that all you say concerning the conditions at Greenfield are true; but as only a part of the truth is told, the true conditions are grossly misrepresented. In order that a proper conception of the condition existing in the City of Greenfield may be had concerning the municipal control of the lighting plant, the following facts will be of interest: Prior to December 15, 1897, the city was paying $70 per annum per arc lamp for its street lighting—this for midnight service—to provide for the payment of which a special tax levy of 25 cents on $100 was made.

On the above-named date the city purchased the lighting plant from the company then operating it at a cost of $18,400; but as there were no funds in the city treasury to meet the obligation, and as the city's indebtedness at the time was up to the legal limit, eighteen $1,000 notes and one $400 note were given in payment. The city agreed to redeem one of these notes every three months, or, in other words, to pay $4,000 per year on the purchase price. This was approximately what the street lighting had been costing prior to the city's control, and this amount was paid promptly without increasing the tax levy above the original 25 cents, so that in less than five years from the date of purchase the entire plant was paid for. The city is now giving an all-night service and the tax levy has been reduced to 15 cents.

During the seven years that the city has been operating the plant all the original pole lines and overhead work have been reconstructed and during the year 1904 alone approximately 14 miles of wire was used in reconstruction work and extensions.

Since acquiring the plant, the city has purchased one 80-light Brush arc machine and one 200-kw. alternating-current generator; between 300 and 400 wattmeters have been added to the service, together with transformers in proportion to the increase of business. Before the city acquired the lighting plant, commercial users of current were paying from 10 to 16 cents per kilowatt-hour, whereas the rates at present are 7 and 8 cents per kilowatt-hour.

The electrical department of the city of Greenfield has no outstanding debts which are past due; but, on the contrary, has about $3,700 in the fund to its credit. While we are in need of additional equipment, which our surplus is too small to procure, I can assure you that the city's financial embarrassment at the present time is in no wise due to the purchase of the lighting plant; for if the equipment is worth anything to-day—and I believe it is—the city is just that much to the good.

Granting to every man his own views concerning municipal ownership, I ask in justice to our little city that the whole truth be given so that we may be placed right before our neighbors.

City Electric Light Plant.
Greenfield, Ind.

The Patent Law Situation.

To the Editor, American Electrician:

For the last 15 years articles have appeared at intervals in the technical press calling attention to the inadequate method of obtaining justice in disputes based upon patents. The last one, by the well-known patent attorney, Mr. Edw. P. Thompson, of New York,* clearly shows some shortcomings of the present method, but he puts matters rather mildly when he says: "As the judge in court is only a legal man, a suit at patent law is nothing more than a burlesque or comedy in the eyes of a technical man."

Many a man who has had the experience of wrong decisions, as well as others who only know about them, charge the judge with being interested or bribed. I, myself, firmly believe in the fairness and strength of character of the judges in American courts, in spite of the many wrong decisions by them and the resulting hardship to many law-abiding citizens; but I wish to point out that the well-known inefficiency of courts in properly dealing with technical cases considerably lowers the prestige of these courts, and may be a direct cause for seeming and actual disregard of laws and ordinances by many.

The concentration of power in large corporations and trusts has also become a feature of the electrical industry, and oppressive methods for removing competition are but natural consequences. Patents are singularly well adapted to further this end, for under the pretext of the desire to enforce laws and rights, suits can be brought which would make manufacturing unprofitable to enterprises of moderate capitalization. Well-planned attacks by attorneys trained for years in such practice, testimony from experts having flexible consciences, and the inexperience of judges in technical matters are three formidable factors for systematically practicing anarchy under the guise of law.

Some ten years ago or more steps were taken by legal profession to overcome the greatest wrongs by presenting a bill before Congress for the creation of a "Court of Patent Appeal." Nothing has been heard of this so far. My inquiry at that time into the probable effectiveness of such an organization resulted in statements which may be summarized somewhat as follows: "It is not all that may be desired, but it is the best we can get at present."

In other words, if a firm has been persecuted for several years and has paid thousands of dollars for legal defence it should be possible to appeal to a court where the subject may be expected to be reasonably well understood and which would enable the weaker party to get justice and not be crushed out of existence. Time has passed for calling attention to facts; action is required by those desiring a remedy from the present state.

Patents are interstate grants and rights and the Federal Government can be appealed to for the desired change. Below is outlined a plan which it is confidently believed will lead to the desired results if every manufacturer of electrical, mechanical or other devices protected by patents, and every inventor, lawyer or other person interested will respond promptly.

It is not believed that a Patent Court of Appeals will give the desired relief and the plan here submitted consists in part in ascertaining from as many representative firms of various industries, lawyers, patent attorneys, judges and inventors, which system may best remedy the existing shortcomings. The plan consists in the execution of the following steps:

1. Everybody interested is requested to examine carefully the various remedies or suggestions submitted at the end of this letter and to select from them the form which he considers best adapted to give the greatest amount of justice at the least expense, or if none of these forms suit, to suggest another way, accompanying the suggestion with a brief explanation. The answer should not be formulated in its final shape before the subject has had four weeks' consideration.

2. The present communication should be shown by inventors, manufacturers and engineers to others, especially manufacturers in other branches, and to patent attorneys and lawyers in their locality, for consideration, judgment and reply in accordance with clause 1.

3. The answers, which shall be considered strictly confidential, are to be addressed to and collected by the editors of the AMERICAN ELECTRICIAN and *Electrical World and Engineer*, such communications to be marked "Patent Law Reform."

4. The correspondence thus collected is to be forwarded to the Bureau of Commerce and Labor, or as suggested by an eminent jurist of St. Louis, if the correspondence is voluminous and representative firms, engineers and attorneys recognize the importance of this matter, a memorial may be prepared and handed, with the communications, by a Congressman or the chairman of the Ways and Means Committee, to the President of the United States, who, according to his judgment, may turn the matter over to the proper department or make suitable recommendations to Congress for its attention and action.

5. In this latter case instructions to Congressmen and Senators by all interested may be desirable, explaining the purpose and results hoped for and asking for their co-operation and support of a bill that will bring about the desired results.

For consideration and selection, the following modifications of the present practice are respectfully submitted in all such legal cases involving patents:

1. A court shall call to his assistance in ruling and deciding in a technical suit an expert uninfluenced by either complainant or defendant.

2. A court shall obtain an expert from the Patent Office selected by the Commissioner of Patents or head of the department in which the patent is classified.

3. A court shall call to his assistance an expert from the Patent Office and another practical or theoretical expert as the case at hand may dictate.

4. A court shall associate with himself a practical and theoretical expert. State or Federal laws to dictate who shall pay for these services.

5. The creation of a lower and upper Patent Office Court as a separate department of the Patent Office. In such a case the complainant informs the lower court that X is infringing his patent No. —— and presents his side; in due course X is notified by the lower court (as at present in a case of interference) to present his case.

a. If considered necessary, lower court official hears cases in different sections of the country at fixed seasons of the year.

b. All matters not involving patents or technical matters to be referred to a local court for decision.

6. Suits involving patents to be handled as heretofore, but all testimony to be sent to Washington for an opinion and assistance from a commissioner, examiner or officer of a department created for this purpose as a separate branch of the Patent Office and manned from the corps of examiners and commissioners of the different departments. Such official to be present at the final hearing of the case and to assist the court in judging the merits of each side.

7. A court of final appeal to be permanently located in Washington and to be formed by the heads of departments or legal lights of the profession.

The opportunity is now open to the individual reader to enter these primaries and give his decisive vote for reform, better patent protection and court ruling. The earnest and vigorous support of everyone interested is desired.

St. Louis, Mo. LUDWIG GUTMANN.

*Electrical World and Engineer, Vol. 45. P. 634.

NOTES.

Automatic Block Signals.—An unfortunate inconsistency appeared in the final installment of Mr. Scott's article last month, on page 423, first paragraph, third column. This should read, "The fact that the initial cost of the installation of the normal danger system is greater than the normal clear system," etc., instead of as printed.

Power Transmission to Stockholm.—It is announced that an agreement has been arrived at between the managers of the Stockholm Gas Works and the Söderfors Bruks A. B. with a view to the purchase of two waterfalls of the Dalelf. These waterfalls, which are situated in the same branch of the Dalelf River, yield about 250 cubic meters per second with a head of 7 meters. With a minimum water supply of 100 cubic meters per second, about 10,000 electrical horse-power would be available in Stockholm, and with 250 cubic meters as much as 25,000 horse-power. The distance is 125 kilometers (about 77.6 miles) from Stockholm.

The Nernst Lamp as a Load Equalizer.—The August number of the little bulletin issued monthly by the Nernst Lamp Com-

pany contains an argument of some merit for the use of Nernst lamps to equalize central station loads, the argument being in brief that by using a very high efficiency lamp it would be practicable to modify the usual two-rate system by charging meter rates during the peak hours and a flat rate during the other hours, the flat rate being presumably graded according to the period of use before and after the peak period.

Portable Telephones.—In order to facilitate the use of telephones, the German Telegraph Department has recently introduced portable telephone instruments in connection with connection boxes, which can be arranged at any desired place, being especially suitable for hotels, restaurants, etc. The connection boxes are fixed to the tables, usually beneath the board; if the customer wishes to use the telephone he has only to ask for the portable outfit which may be fitted immediately to the connection box. An additional fee of only 6 marks per year is charged for each box, while the use of the portable telephone outfit is charged for at the rate of 20 to 30 marks per year. These outfits are used also to allow telephonic communication between vessels anchored in harbors and the telephone system of the harbor town, in which cases the connection boxes are located on the quays and, where necessary, provided with special protective devices.

The Broken Wire. — A correspondent sends us the following simple method of locating breaks in telegraph wires, which he has clipped from a local Pennsylvania paper. The item has only lost the names of the two cities, London and Birmingham, and punctuation marks in its long voyage across the Atlantic; since it was first given to the world by the science editor of London *Tid-Bits* under the heading "When the Telegraph Wire Is Broken." We commend this quasi-scientific and charming effusion to the prayerful consideration of those of our readers who have long struggled with more difficult tests.

> Have you never wondered how when a wire is broken or damaged between two distant cities the operator, sitting in his office, can tell exactly where the accident has occurred?
>
> The explanation is very simple. It requires force to send electricity through a wire. The longer the wire is the greater is the force required. This force is measured, but instead of calling it pounds, as in measuring the pressure in a boiler, electricians call the units of electrical force "ohms."
>
> Suppose a wire between two offices is 150 miles long, and that on a stormy night it gets broken somewhere. The telegraphist knows that when the wire was sound it took just 2,100 ohms to send a current through, or 14 ohms per mile. He now finds that he can send a current with only 700 ohms. He divides 700 by 14, and finds that the break in the wire is fifty miles from his end.

Lectures at the New York Trade School.—Following the usual custom, a series of evening lectures on Steam and Electrical Engineering will be given during the coming fall and winter at the New York Trade School, First Avenue, 67th and 68th Streets, New York. These lectures are intended for practical workers—stationary engineers, firemen, electrical workers and machinists. They present an attempt to satisfy a need for practical information and clear-cut explanation of engineering phenomena and experiences of daily occurrence. The lectures are in the nature of a conversation between the lecturer and his hearers, and questions are freely asked and explanations given, accompanied by illustration and, when possible, experiment. Information as to terms, dates and arrangements can be had on application to H. V. Brill, Superintendent, New York Trade School, 67th Street and First Avenue, New York.

The Utilization of Brown Coal for the Generation of Gas.—At a recent meeting of a German chemical society, Mr. Schott delivered a lecture on this subject. The future utilization of the raw brown coal would have to be looked for by means of gasefication, when the very high percentage of water contained in the coal would be condensed again by the formation of hydrogen in the generator instead of having to be raised to the temperature of incandescence, as in the case of an open fireplace. After cooling, an extremely efficient gas free from any water, which is suitable also for melting purposes, is obtained cheaply. Whereas in the event of its being used for firing under steam boilers, the ratio to common coal is 1 to 3 or 3½, the ratio is only 1 to 2 in the present case. Conditions are as satisfactory in the case of the gasefication of brown coal briquettes when no tarry products liable to interfere with the operation of the generator are obtained, while the fact that more than double the amount of heat energy is stored in the briquettes compensates for the freight charges even for considerable distances.

An Effective Contact Maker.—In branches of electrical work where very sensitive apparatus is employed it is often necessary to make delicate contacts. Especially is this true in physical laboratories and astronomical observatories in connection with accurate clocks and chronometers. It is difficult to make such contacts in the case of a sensitive pendulum, for example, without interfering seriously with its accuracy, and in many laboratories experiments have often been postponed or given up in disgust because of the frictional error involved in making the proper and reliable contacts. In some cases a delicate metal pointer has been attached to the pendulum and allowed to swing through a drop of mercury at the proper time, but this introduces a frictional drag that in some cases is far too great to permit the employment of such a method. A device in use at the Harvard College Observatory in Cambridge, Mass., obviates the friction produced by actual contacts in an ingenious manner. To the bottom of the clock pendulum is hung a small horseshoe permanent magnet. As the pendulum swings over the center of its trajectory the magnet passes directly over a small iron armature mounted on a horizontal spring and attracts the armature toward it without drawing the tiny piece of iron far enough up to make a contact. The air-gap at the moment of maximum attraction is probably not over 1/32 inch wide, but the spring holds the armature back from making an actual contact with the permanent magnet. Attached to the farther end of the spring is a platinum point which makes the electrical contact desired against a fixed platinum stop as the spring moves upward in response to the magnetic impulse. The device works admirably, and the effect of the magnet is simply that of a slight additional mass in the pendulum. The attraction between the magnet and armature lasts effectively but a small fraction of a second, but this is ample for the work of operating the relay contacts.

A New Electrochemical Filter and Purifier—The Edison Electric Illuminating Company, of Boston, has added an electric filter and purifier to the equipment displayed in its Head Place Exhibition rooms. The use of electricity in the laboratory and in domestic work has increased very largely of late, and the purification of water, milk, cider and other beverages is now a matter of widely recognized importance. The new filter, which was made by the Electric Filter Company, of Alliance O., is adapted for almost any class of service, the commercial sizes ranging from 100 to 300 gallons capacity per hour at 90 lbs. pressure. The filter consists of two brass cylinders, tinned on the inside with pure block tin to insure durability and the purity of the product. The smaller cylinder is attached directly to the supply pipe and contains aluminum plates through which the current is passed into the water, forming aluminum hydrate. The aluminum hydrate causes the organic matter to gather in a flaky form of jelly-like consistency, and in case any of the germs escape being killed by the hydrate they are caught in these flakes and together with the water forced through the connecting pipe into the larger chamber, in which is a fine-grained stone through which the water is forced, but which is impervious to the flakes. The enmeshed germs are unable to pass through the stone. In the upper part of the chamber the water is ozonized, which improves its quality. The device is cleaned by taking out the filter stone and scrubbing it with a stiff brush. It consumes about 50 watts or the equivalent of an ordinary 16-c.p. lamp. It is reported that tests made by Dr. F. T. Aschmann, of Pittsburg, on New Castle hydrant water flowing through the purifier at the rate of three pints per minute showed a reduction in bacteria of from 234 to 2 per cubic centimeter, rendering the water practically sterile. Sweet cider treated with the purifier was also rendered nearly sterile, as the innumerable germs in the untreated sample were reduced to 11 per cubic centimeter. The keeping qualities of the cider were also greatly improved, without any impairment of the flavor. In a milk test the bacteria were reduced from 2,891 per cubic centimeter to 27, and Pittsburg water was purified from 360 to 16 bacteria per cubic centimeter.

AMERICAN ELECTRICIAN

WITH WHICH IS INCORPORATED
Electrical Industries.

CECIL P. POOLE, Editor.

Issued on the first of each month by the

McGraw Publishing Company

114 Liberty Street, New York.

Philadelphia Office..........929 Chestnut Street
Chicago Office ....Monadnock Building
Cleveland Office ....Cuyahoga Building
London Office, Hastings House, Norfolk St., Strand

Address all business communications to AMERICAN ELECTRICIAN, 114 *Liberty Street, New York. Matter intended for publication in the reading columns should be addressed to the editor.*

Subscription price, $1 per year, postage prepaid, in the United States, Canada, Mexico and Cuba; $2 in all foreign countries. The date on wrapper shows when subscription expires. Subscribers should give their old as well as their new address when requesting a change in address. This should be received a week in advance of the desired change. No copies are kept on sale beyond fifteen months from date of issue, except in bound volumes.

Advertising rates sent on application. Advertisements received for insertion up to the 25th of the month prior to date of publication. Changes in standing advertisements should be received not later than the 15th of the month to insure their insertion in the next issue.

Remittances should be by check, New York draft, express or postal money order, payable to AMERICAN ELECTRICIAN.

Entered in the Post Office at New York as second class mail matter.

Vol. XVII. SEPTEMBER, 1905 No. 9

The AMERICAN ELECTRICIAN *has the largest circulation of any electrical journal published. Of this issue,* 16,500 *copies are printed. The total number of copies printed so far this year is* 162,000, *or an average of* 18,000 *per issue.*

CONTENTS.

Centrifugal Pumps for Boiler Feeding.

The merits of the centrifugal pump for boiler feeding are attractively presented in this number by Mr. H. F. Schmidt, who points out that such an application would confer the benefit of automatic feed to a higher degree and with simpler auxiliary apparatus than would be possible with reciprocating pumps. His suggestion for automatic feeding is, broadly, to use a balanced inlet valve on the feed-water pipe of each boiler and a ball float controlling this valve according to the water level; the pump or pumps to be driven at constant speed, of course, since variable speed is out of the question with centrifugal pumps, and it would not be advantageous even if practicable. With such an arrangement the personal attendance would evidently be reduced to the minimum and the water level in each boiler would be independent of the other. Preferably several pumps would be installed so that the pump capacity could be adjusted roughly to the needs of the plant. This naturally leads up to the suggestion of using a number of pumps equal to the number of engines in the station and having capacities proportional to those of the engines, provided the station is of the ordinary simple type. In such a case the number of pumps in operation would always be equal to the number of engines and the capacities would be roughly proportional. Speed regulation not being required, the pumps could be driven by induction motors just as satisfactorily as by direct-current machines, or they might, in small stations, be driven directly by the engines; in the latter case attention to the pumps themselves would obviously be reduced to lubrication.

Besides the reduction in the amount of attention required, both as to adjustment and maintenance, there is a conspicuous reduction in the expense of keeping a centrifugal pump in running condition, there being no packings to renew, no cylinder wear and no valves to grind; the only wearing parts are the bearings, which are simple and inexpensive to replace. It is rather difficult to make a comparison between the steam economy of a centrifugal pump and that of a duplex pump; the efficiency of the former at small loads is pretty low, but with graded active capacity, as suggested in the preceding paragraph, there should be no need to operate at very small loads. Of course, a comparison at full loads is readily drawn, but this does not mean much in actual practice. Such a comparison between duplex steam pumps and motor-driven centrifugal pumps would undoubtedly show up in favor of the latter, and it is possible that even a half-load comparison would not put the centrifugal pump in a bad light. A steam pump, it will be remembered, entails considerable loss in the way of condensation and radiation which is not incurred with a motor-driven pump; but this argument does not apply in a comparison of reciprocating and centrifugal pumps unless one is steam-operated and the other motor-driven.

The Selection of Incandescent Lamps.

The incandescent lamp is probably the most familiar piece of electrical apparatus in existence, and for this very reason the most neglected and abused. To many operating engineers it holds little or no interest as long as it emits a reasonable amount of light; the temptation seldom arises to dust off the bulb, improve the distribution of light by altering the location of the lamp, or to plug a voltmeter into the socket for a few minutes to see if the life of the lamps is being shortened by fluctuations of 4 or 5 per cent above the normal. The purchase of a barrel of lamps is a matter of the lowest bid, for the differences between the various makes seem matters of slight importance in comparison with the problem of the electrical supply bill of the establishment.

As a matter of fact, there is a wide difference in incandescent lamps now on the market, and there is little excuse for a large consumer to buy blindly. First cost is always a consideration, but unless the candle-power, efficiency and useful life are in some way taken into account, money is likely to be wasted somewhere. Few persons outside of the lighting field realize the progress at present being made in the way of improved incandescent lamps. The old efficiencies in the vicinity of 3 watts per candle-power are certainly threatened to be bettered by even smaller sizes of lamps, like the Nernst, the new General Electric 2.5-watt metalized carbon lamp, and the widely heralded 2-watt tantalum filament. It would seem easy enough to give competitive lamps a practical life test before purchasing large quantities, and approximate comparisons of relative light-giving power are not difficult. A covered box arranged in compartments with lamp-blacked sides and a few sheets cleanly printed in small type enable very satisfying ideas of the relative usefulness of different styles of filaments, bulbs and reflectors to be obtained. Many plants cannot afford a delicate photometer, but often recourse can be had to the nearest college or high school physical laboratory with little expense and good results. The point is that there is little

or no economy in mere haphazard buying and that a little scientific testing will often pay for itself in the more lasting satisfaction and efficiency obtained from the better grades of lamp now offered in the market.

Making the Best of the Equipment.

In these days of stopping industrial leaks every progressive power station engineer is anxious to do all that he can to improve the operating efficiency of his plant, but in many cases there seems to be little opportunity to do effective work. The engineer may realize the superior economy of the most modern equipment and may have recommended its purchase and installation, but for unknown reasons the owners do not see their way clear to such action, and the plant limps along month after month with a generating and switchboard outfit that would be a credit to a museum of mechanical and electrical antiquities. Cases like this are by no means fanciful, and from the standpoint of the engineer the situation is often discouraging. Given a lot of belted generators, non-condensing engines, aged piping and leaky pumps that keep the force on the move from Monday morning until Saturday night, there is certainly reason to suppose that efficient operation is out of the question, considering the time spent in simply keeping the bus-bars alive. But as one visits plants in different parts of the country it is impossible to overlook the splendid work which is being done by many engineers under the most trying conditions, with the result that the cost of power per unit of output is actually lower than in the case of better favored installations. It is a source of wonder that a kilowatt-hour can be delivered to the switchboard at such moderate cost in some of these plants where the equipment is so far out of date.

In no sense do we advocate the retention of inefficient and wasteful machinery, but making the most of the means at hand is one of the fundamentals of good engineering. It is the old problem of the man behind the gun once more. A natural mechanic will produce a better piece of work with a jackknife than a poor workman will with the most expensive kit of tools, and an able engineer will likewise often turn old equipment to better account than one endowed with less common sense and power of discrimination can do with the latest products of the manufacturers. Surely there should be no plant in which the piping cannot be kept tight, with insulating covering in good condition; in which the coal cannot be regularly weighed; the output recorded from the switchboard readings; the joints in the wiring kept tight, and the engines thrown into and out of service within their limits of economical operation.

In a recently visited isolated plant supplying a large hotel with heat, light and power, the pumps were located in such a narrow passageway that the high-pressure steam cylinder covering had been barked off by passing employees and supplies; the switchboard lamps and instruments were placed too high above the floor for satisfactory readings; there was a careless burning of incandescent lamps near the windows in broad daylight, and lamp cord was run about without regard to the danger of short circuits and fire resulting from contact with sharp metal surfaces; and finally, the machinery was being operated with practically no regard for the load factor. The plant contained one 45-kw. and two 75-kw. generators, the full-load capacities being 410 and 680 amperes, respectively. The load varied from 300 to 350 amperes, and yet one of the larger units was kept in operation while the small machine was held idle, despite the latter's superior economy at the loads indicated. The engineer confided that the switchboard instruments were seldom read, and yet this was a plant equipped with direct-connected units of modern design, reasonably economical coal-handling arrangements, a well-lighted engine room (barring the switchboard) and good boilers. In the winter season there is, of course, an excuse in many cases for not employing the most efficient steam equipment—compound, engines, high pressures, and possibly superheaters—since the exhaust may all be turned into the heating system, but in the warm season it is certainly worth while to use more care in adapting the equipment to the load characteristics.

Perhaps there is no better way for an engineer handicapped by out-of-date machinery to pave the way toward the purchase of better equipment by his employers than to lay before them each week or month the cost of power per kilowatt-hour. Small improvements can often be made at no great cost to the owners, and if the effect of these steps can be shown in the expense account per unit of output, coupled with an intelligent knowledge of what similar plants are doing with better equipment, the arguments are likely in time to become pretty convincing. Every business man values an analysis on the unit basis; he can grasp the situation almost at a glance where the figures are reduced to conceivable limits. Bring the technical quantities with which the power plant deals down to this unit basis in terms of money per kilowatt-hour, and a long step has been taken toward securing the interested co-operation of the owners.

An Artistic Application of Incandescent Lamps.

The advantages of the incandescent lamp in decorative work of all kinds have been increasingly appreciated of late years, and it is safe to say that the problem in artistic illumination which cannot be solved by the filament lamp is yet to be encountered. From the electric sign in Hebrew characters to the exquisite candelabra of the modern ball room, there seems to be no limit to the flexibility of the incandescent light in meeting exacting and variable conditions.

Some of the best lighting effects thus far produced have been accomplished in picture galleries by installing the lighting units in concealed recesses above the pictures, flooding the latter with a soft, clear illumination that serves to bring out every point of interest without drawing the observer's attention to the sources of light themselves. Except in electric sign work, it is fundamentally important that the lighting equipment shall operate as a means and not as an end. In most displays of pictures the illumination is thrown directly upon the objects exhibited, and this is the case with photographs as well as with paintings. An interesting exception to this practice is found in the superb exhibition of photographic positives at the Harvard College Observatory in Cambridge, Mass. The positives or transparencies displayed are photographs illustrating the observatory's telescopic work, and they are hung in a darkened room, the illumination being supplied by incandescent lamps located behind the plates. The resulting effect is remarkably beautiful, and the flood of soft light which pours through the plates gives the observer a fine impression of how the heavenly bodies appear when viewed directly through a large telescope. Some of the enlarged views are of the moon, milky way, etc., and the details are admirably brought out by the incandescent lamps behind the plates. A comparison of the ordinary method of showing special photographic prints by day or lamp light with the scheme adopted at the Harvard Observatory quickly convinces one of the peculiar value of electrical methods of illumination in solving unusual problems. It is, therefore, well worth while for the progressive central station man to be thoroughly primed upon the artistic as well as the ordinary commercial application of electricity.

AN ADJUSTABLE CONDENSER.

BY CLYDE CHALMERS SWAYNE.

Those who are experimenting with high-potential currents, and especially those interested in wireless telegraphy, will find the condenser herein described to be much superior to either Leyden jars or glass plates. It is easily adjusted, small and compact, and not liable to accidental discharge or breakage. Its construction is simple and inexpensive. The capacity will vary under different surroundings, but is so easily adjusted that this can hardly be called an objection.

Fig. 1 shows a sectional view of the condenser complete. All parts are made of brass, except the top, base and handle, which may be made of wood, but are preferably of fibre or hard rubber.

The base, Fig. 2, is made of 1-in. stock and the top, Fig. 3, of 1/2-in., both being 8 1/2 in. in diameter, with holes bored as shown. The brass plates Figs. 4 and 5, are made of 1/32-in. sheet brass, cut to shape and bored as shown. Ten of the former and nine of the latter are required. The plates of each set should be firmly clamped together and made as nearly alike as possible with the facilities at hand.

In Fig. 6 the spindle, *a*, is turned down from 3/8-in. stock; *b* is 11/16 in. in diameter by 9/32 in. in thickness, drilled and tapped for a 5/16-in. standard thread and then sweated on *a*; *cc* are 3/4-in. standard hexagonal nuts and *d* is a 14-20 nut. The hole *e* should be tapped for an 8/32 thread.

In Fig. 7 *a* is a 3/16-in. rod, 5 9/16 in. long, with a 10-32 thread on each end for the distance shown. The nut, *b*, is sweated on. Four rods with accompanying nuts, together with four 1/32-in. washers for each rod, are required.

One 3/8-in. tube, Fig. 8, is needed, 3 5/8 in. long, with an inside diameter of 3/16 in., to fit snugly over one of the rods, *a* (Fig. 7). Figs. 9, 10 and 11 are distance pieces to hold the discs apart. The bearing, Fig. 12, fits in the center of the base for the spindle to rest in, while the bearing, Fig. 13, is fastened to the top to secure the spindle there. The proper tension on the spindle being secured by the screw, *c*, Fig. 13.

The pointer, Fig. 14, is 4 1/2 in. long. It is bent at one end and filed to a sharp point, the other end being tapped to fit in the hole, *e*, Fig. 6. Two circles 4 in. and 4 1/4 in. in diameter should be drawn on the top of Fig. 3, the space between being divided into degrees, or otherwise as desired.

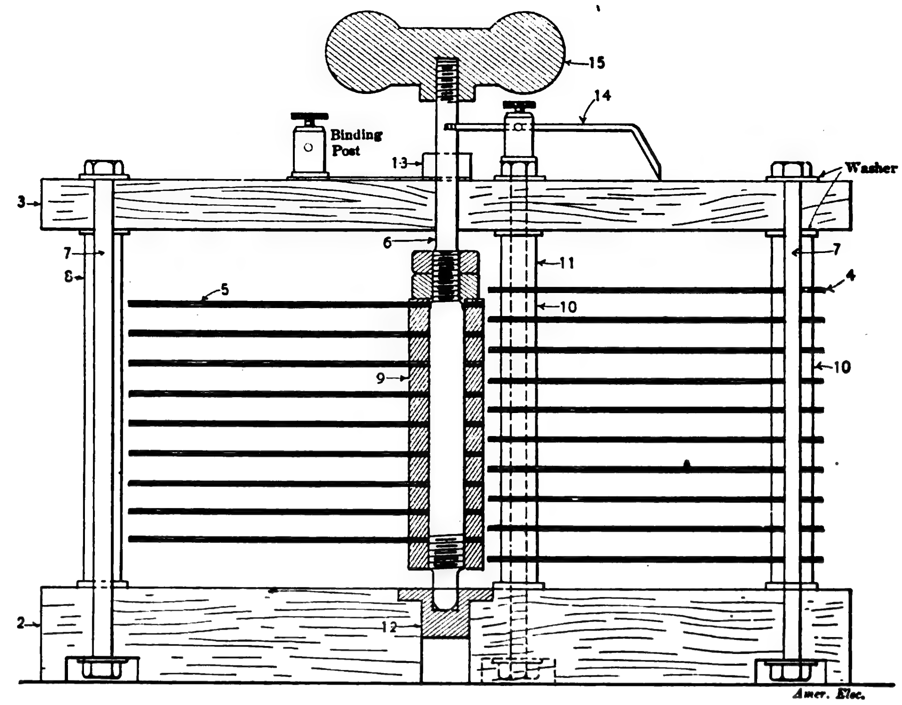

FIG. 1.—COMPLETE SECTIONAL VIEW OF CONDENSER, HALF SIZE.

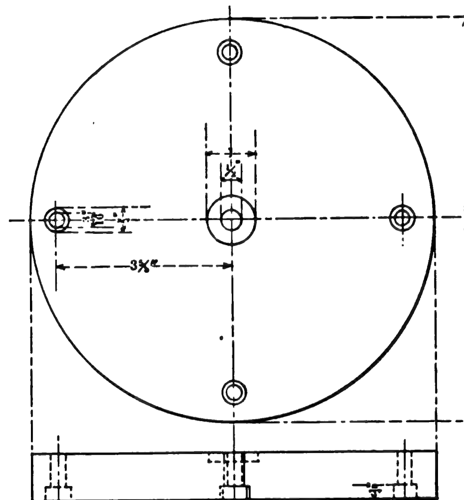

FIG. 2.

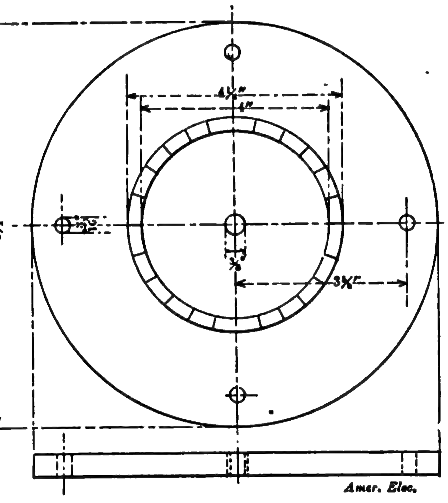

FIG. 3.

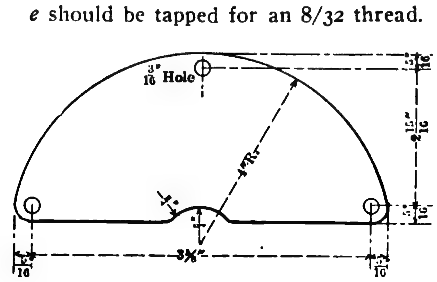

FIG. 4.

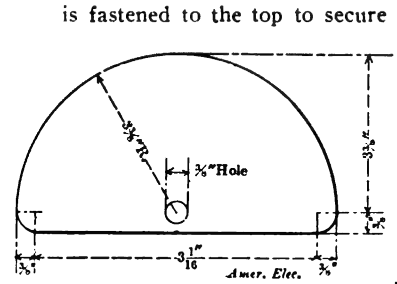

FIG. 5.

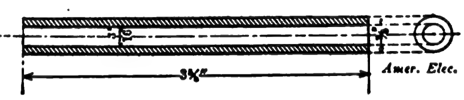

FIG. 8.

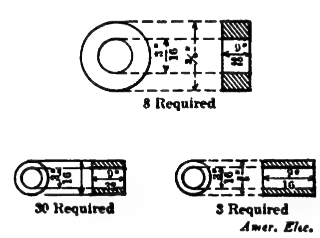
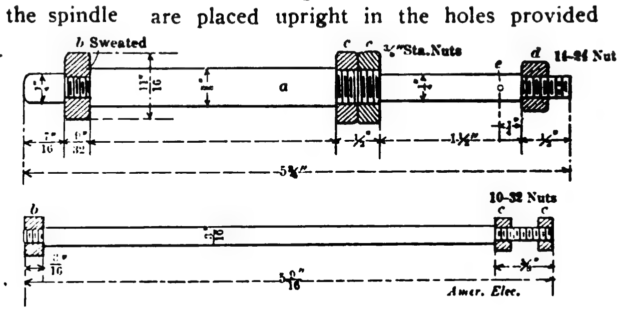
Either wood, fibre or hard rubber may be used for the handle. The dimensions given in Fig. 14 are taken from a radiator valve handle. Two binding posts are required; one of these is placed on top of one of the rods, *a* (Fig. 7), as shown in the sectional view, and the other is placed at any convenient place on the top and connected with the bearing (Fig. 13) by a strip of thin copper.



FIGS. 9, 10 AND 11.

In assembling, three of the rods (Fig. 7) are placed upright in the holes provided for them in the base, a washer being placed underneath and one on top. A distance piece (Fig. 10) is then placed on each rod and then one of the larger plates. An-



FIGS. 6 AND 7.

other distance piece is then placed on each rod, then another disc concentric with the first, and so on until the ten plates are in position. Finally, one of the longer dis-

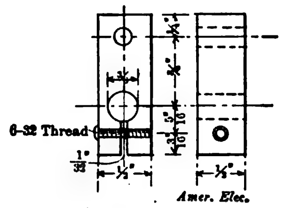


FIG. 13.

tance pieces (Fig. 11) and a washer are placed on each rod. The lower bearing is then fixed in position.

In assembling the smaller or moving plates, the spindle is placed in its bearing and the nut, *b*, adjusted so that its top is just level with the center of the two lower stationary plates. The spindle may then be taken out and the nut sweated on.

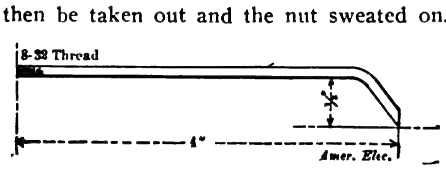

FIG. 14.

When this is done the spindle is replaced and one of the smaller discs slipped on. Then a distance piece (Fig. 9), then another plate, and so on until the nine small plates are in position. The plates should be straightened and placed concentrically with each other. The two binding nuts, *cc*, can be screwed down to hold the plates firmly. The remaining rod can now be put in the fourth hole in the base, with a

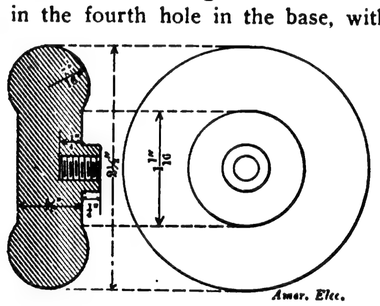

FIG. 15.

washer underneath and one on top, and the tube slipped over it.

Place a washer on each of the rods and then the top may be secured in position by a washer and nut on each rod. The upper bearing can now be slipped over the spindle and secured in position with a wood screw, or if fibre or hard rubber is used an 8-32 machine screw is needed.

The pointer and handle are next put on. The pointer should rest at 180° when the moving plates are entirely outside the stationary ones. A slight turn of the handle is all that is necessary to chance the capacity. Outside the degree circle the approximate capacity can be marked by comparison with a standard. Of course this can only be approximate, as the capacity varies with the surroundings. To make the capacity more uniform, the condenser can be placed in a glass or earthenware jar, with insulating oil around it.

As described, the condenser will vary from about .000626 microfarad when the pointer is at 190°, to about .000126 microfarad when at 360°; i. e., when all the moving plates are inside the stationary discs.

PRACTICAL NOTES ON BOILER-FEEDING APPARATUS.

BY CHARLES L. HUBBARD.

The Injector.

The injector is used extensively in both stationary and marine practice, and exclusively upon locomotives. Its advantages are its compactness and simplicity, having no moving parts when in operation except a light check in certain forms. In stationary work the injector is often used in connection with a pump as a safeguard in case of an accident to the former. The successful operation of an injector depends upon the steam pressure, height of lift, and the temperature of the feed water, and the proper combination of these conditions must be obtained in any case; this makes its field of usefulness somewhat limited. The common form of injector combines two distinct functions, the lifting and the forcing of the water. Fig. 1 shows in diagram the essential parts of the ordinary injector. Steam is admitted through the nozzle *E* and passes through a second nozzle, *F*. The friction between the rapidly moving jet of steam and the air lying between it and the sides of the nozzle *F* causes some of the air to be dragged along, thus producing a reduction of pressure in the chamber, *A*. A partial vacuum being formed in the suction pipe, water is drawn into the injector

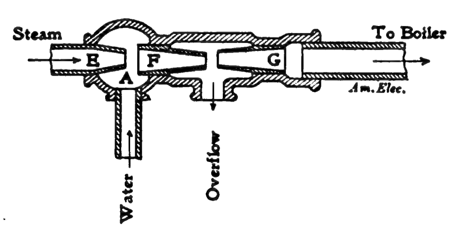

FIG. 1.—INJECTOR.

and thus the first part of its operation is accomplished.

The second part, that is, the forcing action, may be explained as follows: The jet of steam issuing from the steam nozzle, *E*, is condensed by the surrounding water and much reduced in size, while its momentum remains the same. This being the fact, it is able to enter a much smaller opening than that from which it issued, thereby correspondingly increasing the pressure per square inch of section required to stop it. This increase in pressure is so great that the jet not only has sufficient energy to reenter the boiler against its own pressure, but has enough surplus energy to carry in with it a certain amount of feed water. Referring again to the diagram, the steam enters the nozzle, *E*, and flows through the combining or mixing tube, *F*, and is discharged through the overflow. This action soon exhausts the air from the interior of the injector, as already described, and water is drawn up through the suction pipe and discharged through the overflow with the condensed steam. As soon as the water supply has been cut down to the right amount the strength of the jet becomes sufficient to force its way into the boiler through the pipe, *G*. If the injector were made as shown in the diagram there would be a constant dripping from the overflow, because the jet would never be of exactly the right size to enter the tube, *G*, without spattering more or less water from the edges of the opening. This is avoided in practice by making the overflow opening at the top and providing it with a light check valve, which prevents the dripping of water when in use, and yet offers but little resistance when first starting the injector. Injectors of this type are called automatic, because they will re-establish the jet entering the boiler after it has been temporarily interrupted from any cause.

THE REMOVAL OF ASBESTOS FROM ARMATURE LEADS.

BY ARTHUR B. WEEKS.

The accompanying sketch shows an old device with a new application, the device itself having been for years familiar to incandescent wiremen. Its use, especially in connecting sockets in street railway car wiring, is invaluable.

Probably, however, no one has adopted this plan for freeing armature coil leads from asbestos. Naturally, the asbestos is not ordinarily easily removed, and considerable objection has heretofore been raised because of the time and patience required for baring the wire where necessary. With this device it becomes a very simple matter. The tool is grasped firmly with the right

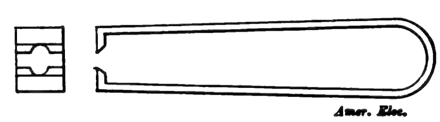

FIG. 1.—TOOL FOR REMOVING ASBESTOS FROM ARMATURE LEADS.

hand and pressed against the wire and with one vigorous pull the insulation may be removed. The tool should not be twisted circumferentially, for if the wire is cut in this way it may break in a short time.

The tool is made of 1/16 in. by ½ in. steel, the cutting edge tempered. If it is a little too stiff the lower portion may be ground down on an emery wheel. The edges should be rounded to make it as easy on the hand as possible.

Asbestos wire is coming more and more into favor for armature and field coils. If plain asbestos wire is used, it is best to dip the coils in a good black insulating paint for the purpose of rendering them moisture-proof and protecting them. Otherwise vibrations might lay the wire bare and cause grounds. Asbestos wire is proof against tremendous heat, and when protected with the proper insulating paint the coil is practically indestructible. The coils should be taped with pure asbestos materials to obtain the best results.

TIME-LIMIT RELAYS.

BY W. T. FERNANDEZ.

Modern practice requires in the installation of large power plants feeding extensive systems of sub-stations, a circuit-breaking device which will automatically open a feeder circuit when serious trouble occurs, but not if this trouble is but of a moment's duration. Various types of relays have been designed to meet the requirements; but it is the purpose of the writer to discuss in the present article only two of the most generally used types with their connections.

The clock type of time-limit relay consists of a clock mechanism which is released by the operation of an armature suspended above a magnet, the latter being energized by current transformers connected to the protected feeder. The time element of the relay is adjusted by shifting the commutator on which the contact brushes bear. This type of relay will not open the circuit on a momentary surge, no matter what its magnitude, unless the duration of the trouble is greater than the time limit set on the relay. Herein lies the disadvantage of this type; since if a relay has been set for 500 amperes with a time limit of two seconds, this limit will be maintained irrespective of the amount of current in the feeder; which, in case of a short-circuit affects the entire system for the length of time for which the relay on the damaged feeder may be set. One brush always bears on the commutator while the other brush only makes contact when either one of the armatures is held down by its respective magnet; thus, if the trouble clears a fraction of a second prior to the expiration of the time limit, one brush is released before the connection bar of the commutator closes the tripping circuit.

The works of this type of relay should be rewound after each release; for since the relay is stopped by a single-toothed wheel actuated by a spring, any defective tension of the stop spring might cause the clock work to entirely unwind after tripping the circuit-breakers, thus rendering the device useless for any additional trouble on the same feeder.

The second type of relay in general use is termed the bellows type, because its action depends on the compression of a bellows by a movable core actuated by a solenoid energized from current transformers connected to the protected feeder. This type of relay has two settings, a minimum and a maximum; the former is controlled by the position of the core with relation to the solenoid and may be adjusted by the threaded knot, *N N*. The minimum setting is usually twice the full load capacity of the apparatus which it protects and the maximum limit is about four times the full load capacity of the apparatus. The high setting prevents the accidental operation of the device, while at the same time preserving its effectiveness in case of real necessity.

The time limit varies directly with the amount of current in the feeder to which the relay is connected as shown in the curve, Fig. 2. It will be noted by reference to the compression line that if the relay is set for 800 amperes with a time limit of two seconds, it will trip the circuit-breakers in 1.6 seconds on the passage of 900 amperes, with a proportionate decrease of time limit as the volume of outgoing current increases. The relay is affected by the heavy lagging currents incidental to a short-circuit on an alternating-current circuit as well as by the effective currents. The apparatus operates instantly under the effects of such a short-circuit, clearing the damaged feeder from the high-tension busbars and the general system in the shortest possible time; so that while this type of relay has all the requirements of a time limit device, it has the additional advantage of becoming instantaneous in its action should the magnitude of the overload on a feeder require such action. Both types of

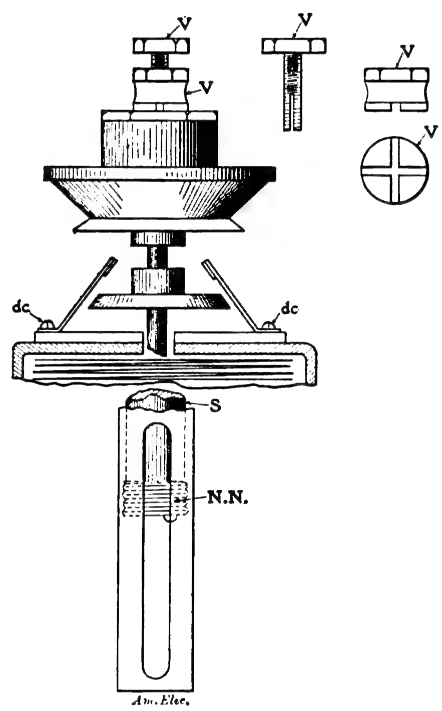

FIG. 1.—BELLOWS TYPE OF TIME-LIMIT RELAY.

instrument require checking and readjusting at regular intervals to insure their proper action. As the operating current of the relay coils is supplied from current transformers connected to the primary leads, it bears a definite ratio to the current in those leads and the test current must be of the same value. For example, if the ratio of the current transformers on a certain feeder be 60 to 1 and the relay is set to operate on the passage of 420 amperes in the primary cables, the current in the relay coils will be 7 amperes, or the primary current divided by the ratio of the current transformer. The test current may be taken from the slip rings of a rotary converter or better still if the machine be six phase, from adjacent lugs of the I. R. T. regulator of a running machine, on account of the lower voltage obtainable from that source. The introduction of a water rheostat, lamp bank or adjustable reactance in the testing circuit, provides a method of control for the testing current.

It is advisable, when possible, to test automatic devices under the exact conditions prevailing in actual service; that is, to time the device from the instant the test current is applied to the time the switch it

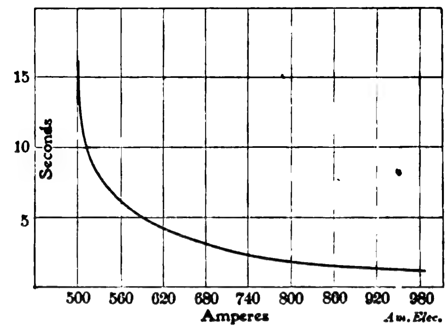

FIG. 2.

is intended to operate opens. If for operating reasons this is impossible, the check and adjustment may be made by disconnecting the tripping circuit from its circuit-breaker and connecting that circuit to a cell of battery with a single stroke bell in circuit with it. The relay is then timed from the starting of its action to the stroke of the bell, as the stroke of the bell indicates the operation of the tripping circuit.

With the clock type of relay, the armature should be held away from the magnet until the current in the coil under test has reached the value required; and then released as a stop watch is released, the watch being stopped at the instant the circuit-breaker opens or the bell rings, depending on the method of checking used.

With the bellows type, the core should be held down until the test current has reached the required value and the time taken from the instant of its release to the opening of the circuit-breaker or the stroke of the bell. When testing a relay the transformers and tripping circuit of the device should also be tested, as a failure of either would render the relay inoperative. Since the transformer wires are usually carried through a double-pole, double-throw switch, which short-circuits the current transformer when closed in one direction and closes the transformer circuit through the relay coil, when thrown in an opposite direction, the testing of the transformers is a simple matter. A pair of test lamps is connected across the center studs in multiple with the relay coil and as the resistance of the lamps is much greater than that of the coil no light will be obtained if the relay coil is closed. If the switch is opened the relay coil is cut out and the lamps are placed directly across the transformer leads and a light is obtained, indicating that the transformer is operative. If the double-pole, double-throw switches are not installed these tests may be made either by disconnecting the necessary wires from the relay after the coil test has been made or by a small coil of wire held against the case of the relay, and connected to a telephone receiver which will indicate the presence of current in the relay coil. It is understood that the feeder, the relay of which is under test for continuity

of coil and transformer wiring, must be carrying some load at the time that the test is made; otherwise there would be no current in the secondary of the current transformers.

The current setting of the clock type instrument is determined by the tension of the springs attached to the free ends of the movable coil armatures; the limiting feature by the distance of the contact bar on the commutator from the brushes. In the bellows type the current setting is made by removing the valves *V V* and adjusting the core, *S*, by means of the threaded nut, *N N*, until the core lifts and trips the switch or circuit-breaker at the required minimum overload—usually from one to one hundred and fifty per cent overload—and after this adjustment has been made the time limiting feature is introduced by adjusting the valves *V V* until the required time limit and overload are obtained.

Once set the bellows type of instrument usually remains reliable; but as a precautionary measure the relays should be tested and adjusted at regular intervals and the tripping circuit every time the apparatus it protects is placed in service. Such a test may be made by connecting a pair of test lamps across the clips *dc* when the switch or circuit-breaker is closed. If a light is obtained it indicates that the circuit is all right, and if no light is obtained an open circuit exists which of course should be repaired before the apparatus protected by that particular relay is placed in service.

Where hand-operated oil switches are supplied with a tripping solenoid connected to a relay, they are usually limited as to the amount of current they may break by a second device termed a limit relay, the function of which is to open the direct-current tripping circuit of the time limit relay, if the volt-amperes, or in other words the short-circuited and incidental lagging currents, exceed the safe breaking capacity of the switch; thus preventing the operation of that relay and throwing the duty of breaking the feeder circuit upon the central station oil switches.

The setting of the limit relay is determined by the known breaking capacity of the switch connected to the time limit relay, the tripping circuit of which is carried through the limit device, and is adjusted by altering the position of the core, by raising or lowering it in its solenoid.

It is advisable to test the bellows for leakage each time the relay is tested, by raising the core as high as possible after the valve, *V*, has been removed, and holding a finger tightly over the valve port; then releasing the core and noting if it drops with any perceptible speed. If so a leak in the bellows may be looked for, and as such a leak will radically alter the time limit, a new bellows should be installed. Defective valves should be replaced with new ones at once and the tripping circuit contacts brightened by crocus cloth each time the apparatus is tested. It is unnecessary to state that absolute cleanliness and absence of dust is essential to the proper operation of overload and time limit devices.

OPEN FEED-WATER HEATERS AND THEIR APPLICATION.

BY W. T. EDWARDS.

It has always been understood that if the condensation of the exhaust steam, with its attendant heat, could be saved and used again, greater economy would result. The great objection, however, to using the condensed steam was the damage caused to the boiler by the cylinder oil entrained with the steam. How to adjust this difficulty has been the subject of much study. It was finally concluded to be next to impossible to remove the cylinder oil from the exhaust; so it was decided to collect as much of the heat as possible without permitting the steam to come into direct contact with the feed-water. As a result, the closed heater was gradually developed.

If the tubes remained clean, or could be kept so with little trouble, the efficiency of the closed heater would always remain the same, but the tubes foul, and become defective from various causes, so that the heater is constantly losing in economy.

By removing the cylinder oil from the exhaust steam, and thus eliminating the possibility of damage to the boiler from that source, it becomes safe to abandon all devices for separating the exhaust steam and feed water and allow them to mix. The loss in efficiency is thus eliminated.

From the foregoing it is evident that, granting the possibility of removing the oil from the exhaust, the superiority of the open type of heater over the closed type is no longer a question.

From the construction of the open heater it is evident that a given quantity of water under ordinary conditions can be heated to a higher temperature with less steam than in the closed heater. Where engines are run condensing the open heater offers an opportunity for driving off the air and g[illegible] from the feed water, which is in itself a favorable point. An opportunity is also given for precipitating and taking out of the water some of the most prevalent and troublesome scale-forming impurities, together with mud and other solid matter. Any means of keeping scale-forming impurities from reaching a boiler should be welcome, as a boiler is a very poor place to purify water. The open heater can be easily cleaned and put back in commission in less than two hours, depending, of course, on the size and condition of the heater; while it is well night impossible to thoroughly clean both sides of the tubes in a closed heater, and any cleaning requires disconnecting the piping with its attendant loss of time.

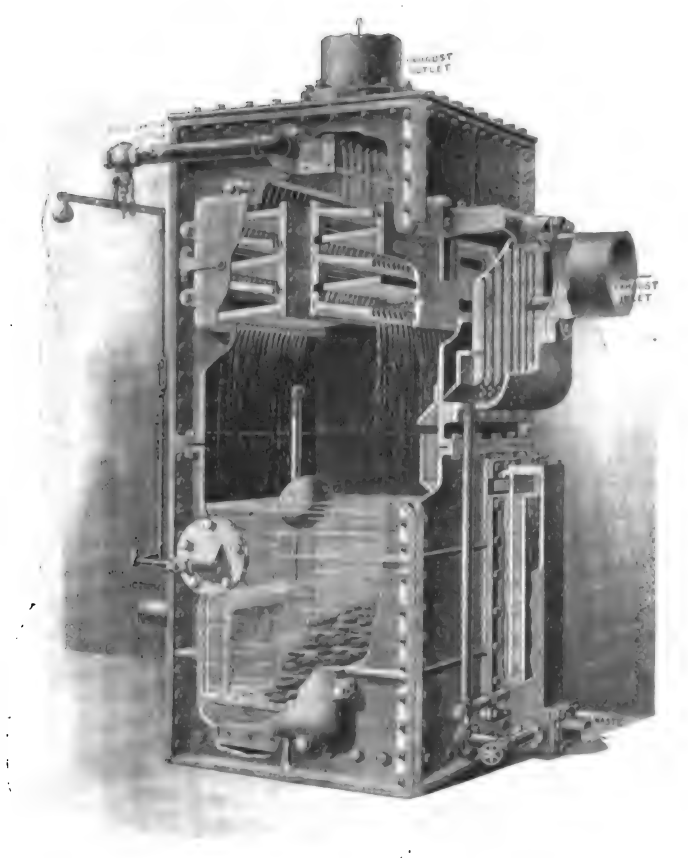

FIG. I.—COCHRANE FEED-WATER HEATER AND PURIFIER.

From a mechanical viewpoint the open heater is preferable because it is under atmospheric pressure, or at most, less than five pounds back pressure, whereas the closed heater is under considerable pressure. Therefore it is not only much easier to keep an open heater free from leaks, but in its construction cast-iron shells may be used, which, together with copper and brass fittings, resist the corrosive action of the air and gases in the water; whereas the wrought-iron or steel shells of the closed heater are very susceptible to this action.

The pumping of hot water is not as difficult as some make it out to be; the secret,

if there be any, is to have the hot water enter the pump with sufficient head to raise the valves from their seats and fill the suction chamber. When that is done and the proper valves used, it is only a question of selecting a pump of the proper size to do the work.

It is only by providing a successful oil

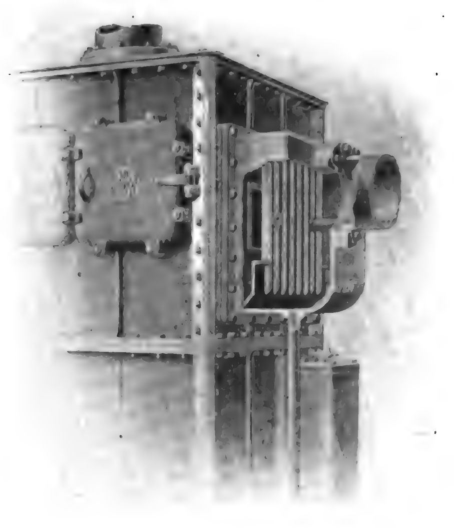

FIG. 2.—DETAIL OF OIL SEPARATOR.

separator that the open feed water heater becomes a possibility.

Among the heaters of this type on the market the Cochrane, manufactured by the Harrison Safety Boiler Works, of Philadelphia, Pa., occupies an enviable position, due to its efficient operation achieved after years of study and experiment. This is due to the oil separator used in connection with it. Fig. 1 shows the heater very clearly. The exhaust enters the exhaust steam inlet and comes in contact with the corrugated baffle plate of the oil separator, which intercepts and collects the oil, the steam passing around the sides of this plate and into the heater, where it mingles with the feed-water. All entrained gases and steam not condensed pass to the atmosphere through the vent pipe or exhaust outlet.

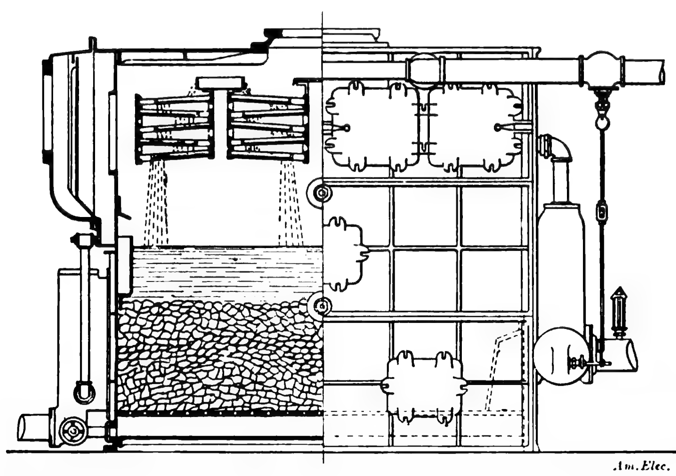

FIG. 5.—HALF SECTION AND FRONT ELEVATION OF OPEN FEED-WATER HEATER, SHOWING TRAY AND CLEAN-OUT DOORS.

The feed-water enters the heater through the cold-water supply pipe and discharges on one set of trays; flowing over the serrated edges in broken spray onto other trays lower down and so on to the bottom, where it passes through a bed of coke supported on a perforated plate, into the pump suction. The cold-water supply is governed by a valve in the supply pipe, which is operated by a ball float.

For removing the oil that collects in the separator, a pipe is connected to it and to a water seal on the waste pipe to the sewer or drain. Connected to this same

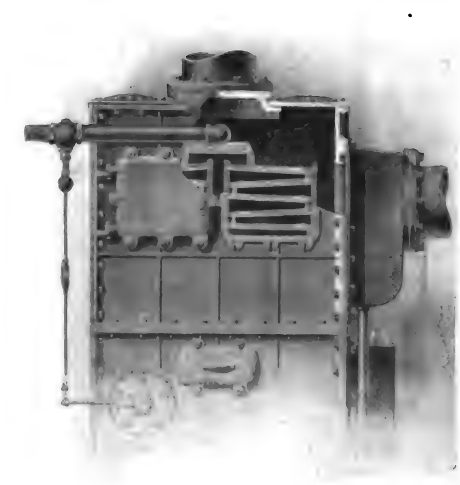

FIG. 3.—REMOVABLE TRAYS AND METHOD OF INTRODUCING COLD WATER.

seal is the blow-off from the bottom of the heater.

Except in the smaller sizes of heaters, which are cast in one piece, each side is formed of one or more cast-iron plates, strongly ribbed, and bolted together at the flanges; all being made steam and water tight with rust joints calked from the inside. Suitable stay tubes and bolts are used in the larger sizes, so that the shells will not be affected by the pulsations of the exhaust steam. The top and bottom plates are also made of cast iron. The oil separator is bolted on the outside of the shell. It is self-cleaning, and is shown in detail by Fig. 2.

The trays, over which the water flows and which form receptacles for the collection of sediment, are placed in the upper part of the shell. They are interchangeable and removable, and the number and arrangement vary according to the size of heater. Each is inclined, and the edges over which the water flows are serrated for the purpose of breaking up the water into spray. The trays are held in place by cast-iron guides, securely bolted to the shell of the heater in such a manner that they cannot be dislodged by pulsations of the exhaust, though they can be readily removed through the cleaning-out doors. Each set of trays is

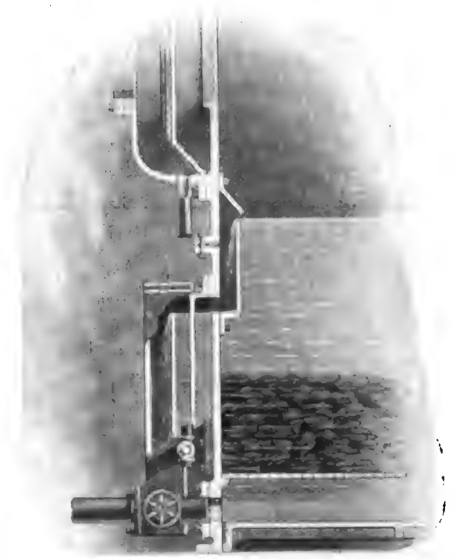

FIG. 4.—WATER TRAP, SKIMMER BOTTOM BLOW-OFF, COKE AND COKE TRAYS.

suspended in the steam space, with ample passages between the supports and the shell for the free movement of the steam. The trays are shown by Fig. 3.

There is a combined skimmer and blow-off, located just above the working level, which extends the width of the heater, for the purpose of flushing off the top layer of water with its lighter, or floating impurities. It is drained through an opening in

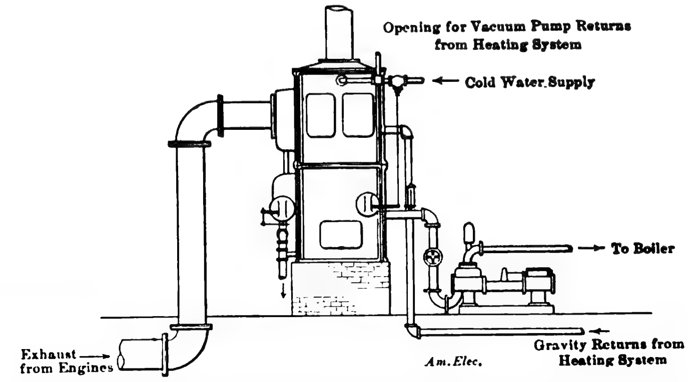

FIG. 6.—SPECIAL HEATER AND RECEIVER PASSING EXHAUST THROUGH HEATER.

the side of the heater into a water seal, as shown in Fig. 4.

The pump outlet is covered by a hood, open only at its lower, or under edge, for the passage of water. This hood extends

below the perforated plate on which the coke bed rests, thus compelling the water to pass through the coke filter before it enters the pump. This can be seen by reference to Fig. 1. The hood is vented by a pipe leading to a point above the working level to prevent air-logging and consequent interference with the flow to the pump, and also to prevent possible syphoning of the water from the heater.

For cleaning the heaters provision has been made to facilitate the operation and to make it possible to clean and examine all parts without disturbing any connections. The faces or joints of all cleaning doors and flanged openings are machined, and standard bolts slipped in slots are used for securing these doors. The tray doors, however, are hinged, so that they may be swung to one side; this is true of all heaters except those the shells of which are cast in one piece. Studs are used to secure the cleaning doors of these heaters. Fig. 5 shows a drawing of one of the heaters and illustrates very clearly the clean-out and tray doors.

When installing an open heater some rules must be observed very closely, while others are not at all important. For instance, it is unimportant where the heater is located with relation to the boiler and engines; but it must be set higher than the pump supplying the water to the boiler by at least two feet. As no pump will lift under pressure and any excess of pressure may injure it. If all of the exhaust steam passes through an oil separator, the drip may be brought down and discharged into the heater, below the water level. If the steam has not been purified the drip should not, under any circumstances, be brought back into the heater, but should be discharged into the sewer.

Conditions under which the open heater may be installed vary, and require different treatment. In some instances all of the exhaust may be passed through the heater, in which case the general arrangement shown by Fig. 6 is applicable. This shows a heater arranged in a heating or drying system; the steam passing through the heater and then into the heating system. As will be seen, the exhaust main is run direct from the engines, pumps, etc., to the steam inlet opening of the oil separator, and from the top of the heater to the atmosphere, both pipes being the full size of the exhaust line. Under no circumstances should any exhaust steam be allowed into the heater before it has been purified of oil. The illustration needs no further explanation, except that attention might be called to the location of the boiler feed-pump.

Fig. 7 shows a heater used to "draw the supply" or used as what is sometimes called an "induction" heater; that is, there is no circulation of steam through the heater, only enough steam being used to raise waste, through the water seal on the heater, if convenient, or through a trap.

The cold water supply may be taken from any convenient source, having head enough to force the water into the heater against the maximum back pressure, or it may be pumped from a well or pond. It is also feasible to use gravity returns, or the water that has been used in the cooling jacket of an air compressor. The gravity returns from a heating system should be water sealed and enter the heater at the regular opening provided for them, unless the returns come back at a comparatively low temperature, in which case they should be entered into the top of the heater and passed over the trays in the regular way. Owing to the cold injection water used in connection with vacuum pumps on heating systems, the tem-

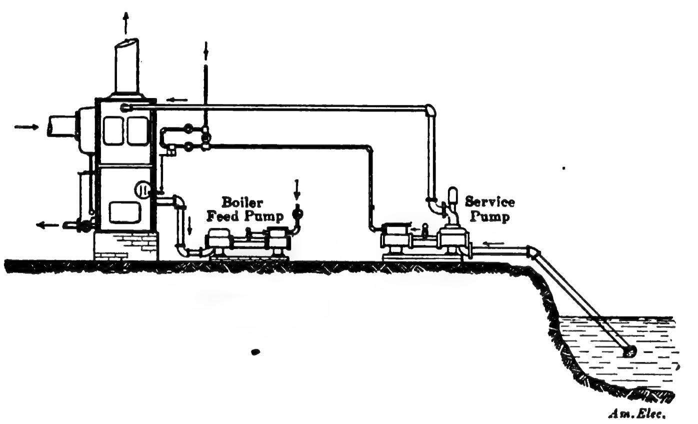

FIG. 8.—HEATER RECEIVING ITS COLD WATER SUPPLY FROM POND OR WELL.

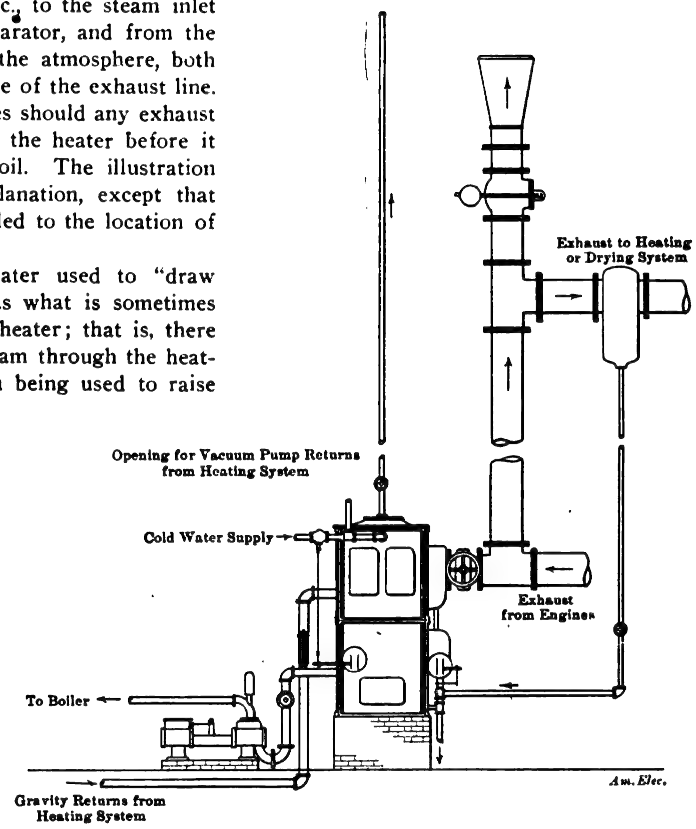

FIG. 7.—SIMPLEST METHOD OF DRAWING THE SUPPLY AND BY-PASSING THE HEATER.

very hot water by suction, there must be head enough to lift the pump-suction valves and keep solid water against the piston; the water must flow into the piston chamber. The pump should be fitted with brass piston rods, metal valves, and the rods and piston fitted with metal packing.

The waste pipe from the trap on the heater is for draining the oil from the separator, the overflow from the heater and the blow-off. It should be of full size and should lead without obstruction to a drain or sewer. The discharge should be lower than the opening in the heater, and no valves of any kind should be placed in this pipe, nor should it be used for any other purpose.

When the heater is under back pressure the valve casing of the back-pressure valve should be drained externally from a point just above the disc, to prevent water from accumulating on the disc and creating excessive back pressure. This is necessary because the heater is not designed to work the temperature of the water to the highest possible point; under such conditions it is necessary to provide a vent connection to allow the escape of gases liberated from the water, otherwise the heater would become air-bound, preventing the steam from entering the heater, and the temperature of the water consequently falls.

The best method of venting is to provide a small pipe from the top of the heater to the atmosphere, carrying this pipe from eight to ten feet higher than the top of the exhaust, and placing a gate valve in this pipe, for the purpose of graduating the area of the vent, opening and closing it until the best results are obtained. The valve is shown on the vent pipe in Fig. 7.

When the heater is installed on the induction system, it is necessary to place an independent oil separator in the branch leading to the heating system, so that the exhaust used for heating will be free from oil. This separator must be trapped to perature of the water delivered to the heater is usually much lower than when returns come back by gravity; therefore it is necessary to pass this water over the trays in the heater, so that it may be heated to the highest possible temperature. An opening is provided for this purpose in the top of the smaller sizes of heater, while in the larger sizes a tee connection is provided in the cold-water supply pipe, between the regulating valve and the opening in the heater. Provision should be made for venting the returns to get rid of the air before the water enters the heater. This may be done by discharging from the vacuum pump into a standpipe or tank open to the atmosphere, and allowing the water to flow into the heater by gravity. The discharge from the tank, or standpipe, to the heater should have a water seal of sufficient depth to prevent the pressure in the heater from blowing the seal.

Where the water is taken from the cool-

ing jacket of an air compressor the connection may be made to the supply pipe, as described for the vacuum pump returns, providing the water from the cooling jacket is less than is required for the heater. If the quantity is more than is required for the boiler feed, a tank or standpipe, as described for the previous case, may be adopted.

The cases where it is necessary to take the water supply from a river or well are rare, but when such a one is found it is customary to use a service pump for delivering the water to the heater. The operation of the pump is governed, and the supply of water regulated by using a balanced valve in the live steam line which is controlled by the float in the heater. This arrangement is shown by Fig. 8. As will be understood this layout is only used where it is impossible to get the water under pressure. The examples cited have had their application only to engines which are run non-condensing; the open heater described is not, however, confined in its usefulness to such plants.

Fig. 9 shows the heater applied to a condensing system, with an oil separator in the main exhaust line. In this illustration is shown a Cochrane horizontal vacuum oil separator with independent tank drainage. The exhaust steam from the condensing engine is passed into the separator through a tapering nozzle piece so as to reduce the velocity of the steam passing through the separator. It is this feature more than any other that has made the separation of oil from steam possible. This oil, together with water removed from the steam by the separator, drains into the tank shown. A vacuum is maintained on this tank equal to the vacuum on the separator by means of an equalizing pipe, thus insuring the complete drainage of the separator. When water accumulates in the tank a float operates a whistle which warns the attendant that the tank should be emptied. By closing the valves in the drip line and equalizing pipe, and opening the discharge from the tank and admitting live steam, the contents of the tank may be quickly discharged, and by reversing these operations the separator and tank are again placed in service.

In a condensing plant the amount of available exhaust steam from the auxiliaries is usually limited so that all the steam is condensed before a temperature of 212° is reached for the feed-water. It is therefore obvious that a heater such as described insures a considerably higher average temperature than when all of the water for the boilers must be heated with the limited amount of exhaust steam, and the condensed exhaust itself wasted through drips.

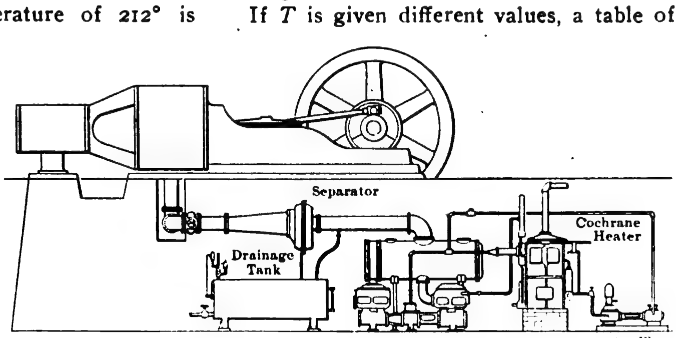

FIG. 9.—ARRANGEMENT OF OIL SEPARATOR AND OPEN HEATER IN CONDENSING PLANT.

It will be noticed in the illustration that the surface condenser discharges into a standpipe, the water flowing into the heater, and the supplementary water being admitted through the regulating valve. It might be mentioned that the drainage tank may be replaced by a good make of return trap. As by the use of these heaters nearly all of the exhaust is returned to the boiler, the economy is obvious, when water must be purchased at, for instance, $1 per 1,000 gallons.

The advantages to be had from the use of the open heater are not alone confined to the larger power stations, but anywhere that steam is generated. They are built in units as small as 50 horse-power and as large as 15,000 horse-power.

A CONVENIENT METER TESTING METHOD.

BY C. A. CORNWALL.

In all meter-testing departments, it is customary to test any meter when returned into stock and find its error percentage. If this error is within certain limits, and the meter is otherwise satisfactory, no further testing is needed, but if, on the other hand, it is found to be running either fast or slow, beyond the allowable limit, it becomes necessary to recalibrate it. The following method of testing meters has been worked out by the writer and found to be entirely satisfactory, giving accurate results and saving an immense amount of time.

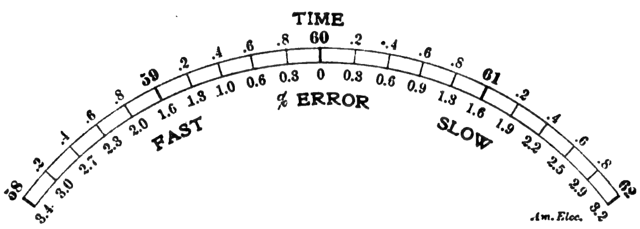

FIG. I.—TIME ERROR SCALE.

The general formula for finding the load which a meter is carrying is $W = \frac{R}{T} \times K$, in which W = load in watts; R = revolutions of the disk; T = time in seconds, and K = calibrating constant of the meter.

If the time, $T = 60$ seconds and W be made such that R will be a whole number in that time (about half load should be used), the actual time, as shown by a stop watch, required by an accuate meter to make. R revolutions will be equal to T in the formula; if this is not the case the percentage of error has to be worked out.

If T is given different values, a table of percentage errors can be worked out for these values, and for all sizes and makes of meters this table will be found correct, provided the proper values of W and R for each case are used.

A time-error scale, made out in a convenient form, is given herewith; also the correct values of W and R for a few meters of different makes and capacities.

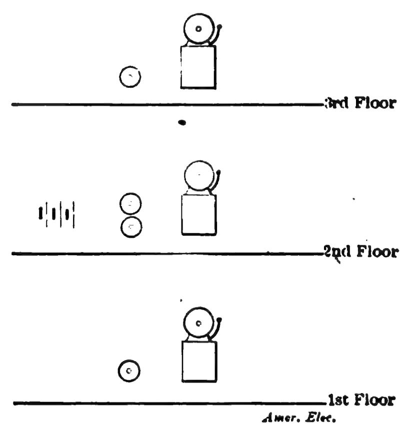
Letters on Practical Subjects

Communications intended for publication in this department must be received at this office not later than the 15th of the month prior to the date of publication.

Problem in Bell Wiring.

I have a problem in bell wiring which I would like to submit to your readers for their consideration. A house has three bells, one on each floor. A push button is situated on the first floor, two push buttons and a battery on the second floor, and a push button on the third floor. The problem is to connect the bells in such a manner that the push button on the first floor will ring the bell on the second floor, the push button on the third floor will ring the bell on the second floor, and the push buttons on the second floor will ring the bells on the first and third floors. Not more than three wires can be used in connecting each floor, and there is no communication between the first and third floors.



PROBLEM IN BELL WIRING.

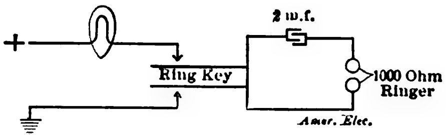
J. H. GAUSE.

Wilmington, Del.

Rise of Potential in Telephone Circuit.

I have experienced a little trouble which may interest your readers. On a pulsating circuit with an e.m.f. of 40 volts at 1,000 pulsations per minute I have connected a polarized ringer (1,000 ohms) through a 2-m.f. condenser and a 200-ohm lamp, as shown in the accompanying sketch. When the current is thrown on the line and the

bell is rung the potential rises to 50 volts, and when the condenser is cut out the potential drops to 26 volts. I would like



RISE OF POTENTIAL IN TELEPHONE CIRCUIT.

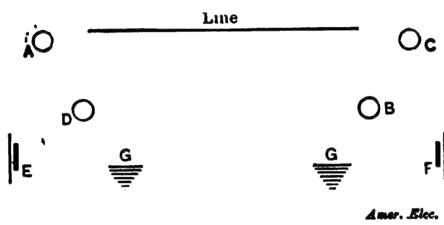
an explanation as to how the extra 10 volts are obtained while the bell is being rung.

N. P. BETHELL.

Washington, D. C.

Problem in Telephone Signaling.

I send herewith a problem which puzzled me some time ago. I found it to be one of the finest bell signaling systems for private line telephones I have ever used, and believing that these problems are as beneficial



PROBLEM IN TELEPHONE SIGNALING.

as any department of your paper, since they furnish information of real practical value to the worker, I submit it to my fellow readers. The problem is to ring the bell at A from the push B and the bell C from the push D and use both batteries E and F at each operation. Only one line wire and a ground return can be used.

W. H. RIGGS.

Everett, Wash.

Problem in Telephone Lamp Connections.

I desire to submit the following problem: Connect the two lamps and the two transfer jacks shown in Fig. 1, so that with a plug inserted in either jack both lamps will be lighted and with both plugs in or out the lamps will be extinguished. I have this transfer in operation here and expect it will be of some interest to your telephone readers.

C. H. FREDERICK.

Zion City, Ill.

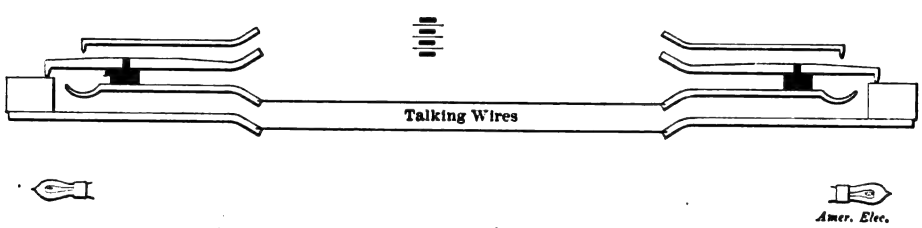


FIG. 1.—PROBLEM IN TELEPHONE LAMP CONNECTIONS.

Mr. Merrill's Bell Connections.

The accompanying diagram is offered as a solution of Mr. Merrill's problem in bell circuits published in the July number. The diagram shows a parallel wired system involving the use of two 2-point and two 3-point push buttons. By pressing the button P, drop No. 1 will fall and bells A, B and C will ring. By pressing button X, bells A and B will ring. Pressing button Y causes

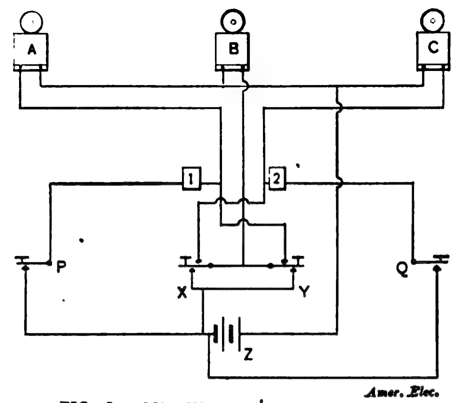

FIG. 1.—MR. WILCOX'S SOLUTION.

the bells B and C to ring, and by pressing the button Q drop No. 2 will fall and bells A, B and C will ring.

E. A. WILCOX.

Scottdale, Pa.

[The foregoing solution was omitted last month by mistake.—EDITOR.]

Mr. Brode's Problem in Mechanics.

The question in mechanics by Mr. Brode in the August number lends itself very readily to a practical solution. Representing the reactions at the supports by R_1 and R_2, it is obvious that $R_1 + R_2 = W$, or the total weight of the beam. Being of uniform weight, the lever arm of each section may be taken at the center of gravity of each section, which in this case will be one-

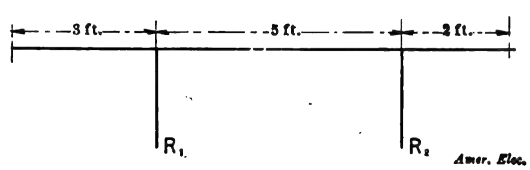

FIG. 1.—MR. VON DANNENBERG'S SOLUTION.

half the length of the section. With R_2 as a fulcrum,

$$R_1 \times 5 = (8 \times 4) - (2 \times 1),$$

whence $5 R_1 = 32 - 2$, or $R_1 = 6$;

with R_1 as fulcrum:

$$R_2 \times 5 = (7 \times 3.5) - (3 \times 1.5),$$

whence $5 R_2 = 24.5 - 4.5$, or $R_2 = 4$.

C. O. VON DANNENBERG.

Schenectady, N. Y.

The following is a solution of Mr. Brode's problem in mechanics. The weight, 10 pounds, acts at the center of gravity, which in this case is at the center of the plank. The reactions at the two supports

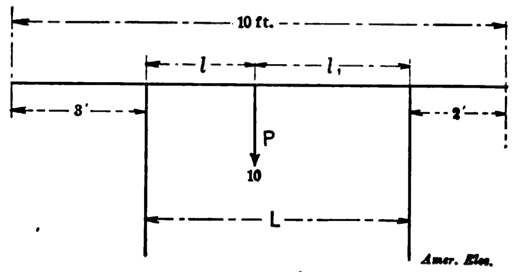

FIG. 2.—MR. ROMINGUEZ'S SOLUTION.

are determined from the following equations:

$$R_1 : P :: l_1 : L,$$

and

$$R_2 : P :: l : L,$$

so that $R_1 = P l_1 \div L$, or $(10 \times 3) \div 5 = 6$ lb., and $R_2 = P \times l \div L$, or $(10 \times 2) \div 5 = 4$ lb.

MANUEL ROMINGUEZ.

Guanajuato, Mexico.

Mr. Brode's problem in mechanics may be solved as follows:

Let x = weight upon the left-hand support; then $10 - x$ = weight upon the right-hand support. Taking moments about the center of gravity and making them equal to each other, as they must be to produce equilibrium, we have $2x = 3(10 - x) = 5x = 30$, or $x = 6$, the weight on the left-hand support. Since the entire weight is 10 pounds, the weight supported by the right-hand support must be the difference between 10 and 6, or 4 lb.

Athens, Ohio. A. A. ATKINSON.

I think the accompanying solution is correct for Mr. Brode's problem published last month:

$$3 : 2 :: x : y,$$

whence $2x = 3y$, or $2x - 3y = 0$.

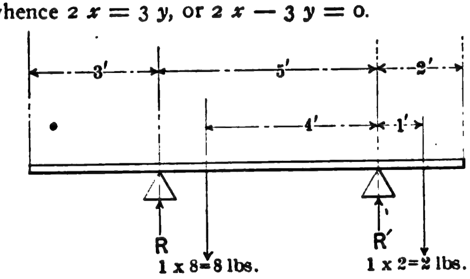

FIG. 3.—MR. BURTON'S SOLUTION.

Since $x + y = 10$, combining the equations we have

$$2x - 3y + 0$$
$$2x + 2y = 20$$
$$- 5y = - 20,$$

whence $y = 4$ and $x = 10 - 4$, or 6.

Greensburg, Pa. R. B. LONG.

[This solution was also received from H. A. Fiske, Georgiaville, R. I.—EDITOR.]

Mr. Brode's problem in mechanics in the August issue may be solved readily by application of the well-known principle of moments of forces. Let R equal reaction of the left support and R' equal reaction of

the right support. Taking moments about the right support in Fig. 3, we have

$$(R \times 5') \div (2 \times 1') = (8 \times 4').$$

From which

$$R = (32 - 2) \div 5 = 6 \text{ lb.}$$

Taking moments about the left support in Fig. 4, we have

$$(7 \times 3.5) = (R' \times 5) \div (3 \times 1.5),$$

whence

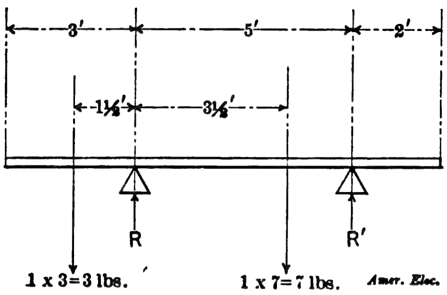

FIG. 4.—MR. BURTON'S SOLUTION.

$$R' = (24.5 - 4.5) \div 5 = 4 \text{ lb.}$$

The left support, therefore, sustains a pressure of six pounds and the right support four pounds.

Baltimore, Md. FRANK B. BURTON.

[A somewhat similar solution to the above was received from J. O. Villars, Williamson, Pa.—EDITOR.]

In Mr. Brode's problem in mechanics the weight may be regarded as located at the center of gravity of the plank. Representing the weight on the support A by the letter x, the following equation is true from the principle of moments:

$$5\,x = 30,$$

whence $x = 6$.

The weight on A being 6 lb., the weight supported by B must be 4 lb.

Oakland, Cal. H. F. MUNSON.

Mr. Brode's problem in the August number may be easily solved by inspection, although the process of reasoning used is not applicable to all cases. The plank being of uniform weight, the 3 feet will balance 3 feet on the other side of the support, and the 2 feet will balance 2 feet, so that if the board were cut 6 feet from the left end both pieces would balance. The weight on the supports would obviously be 6 pounds, and 4 pounds, respectively.

Brooklyn, N. Y. J. T. COE.

[This solution was also supplied by C. O. von Dannenberg, Schenectady, N. Y., and A. A. Atkinson, Athens, Ohio, and is identical with Mr. Brode's own solution.—EDITOR.]

In answer to Mr. Brode's problem I beg to submit the following solution. For all practical purposes it will be correct enough to assume the beam to be without weight and equivalent concentrated loads situated at the center of gravity of each section, as per sketch. Lay off 1—2 = 3 pounds, 2—3 = 5 pounds and 3—4 = 2 pounds. Select any point, as P, and construct the force polygon by drawing the lines 1—P, 2—P, 3—P and 4—P. In a vertical through the first weight, 3 pounds, select a point, as a, and draw a—b parallel to 1—P, projecting it on the support R at b. Draw a—c parallel to 2—P, c—e parallel to 3—P, and d—e parallel to 4—P, projecting to a point in the support R_1. Join b and d and draw the dotted line in the force polygon, parallel to b—d. This intersects the line 1—4, dividing it into two parts proportional to the reactions of the supports, and, measuring it

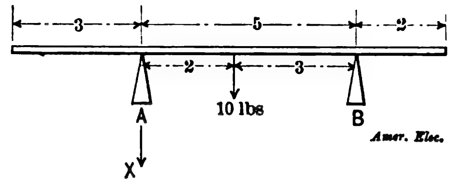

FIG. 5.—MR. MUNSON'S SOLUTION.

according to the scale used, $R = 6$ pounds and $R_1 = 4$ pounds.

York, Pa. CARL E. FREEMAN.

[A similar solution was also received from J. O. Villars, Williamson, Pa.—EDITOR.]

In answer to Mr. Brode's problem in mechanics, I beg to submit the following solution: Consider the pressure at A and B resisted by a force of A and B pounds, respectively, acting upward as indicated. Make three divisions of the plank three feet, five feet and two feet. Now the downward force on the three-foot section is three pounds, and acts as if concentrated at the geometric center, i. e., one and one-half feet from A. The forces and position of

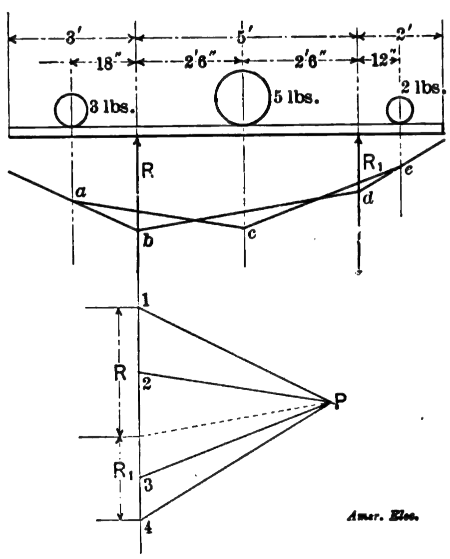

FIG. 6.—MR. FREEMAN'S SOLUTION.

the sections are as shown. The weight on the two supports is ten pounds. There are three forces acting downward which must be equal to the upward forces if the body is at rest. Hence,

$$A + B = 3 + 5 + 2 = 10.$$

Since there is a pressure upward at B, the moment due to the force B about A is $5\,B$, the moment due to C is 3×1.5. The body would revolve and fall to the left of A if the moments due to D (equal to $5 \times 2\frac{1}{2}$), and E (equal to 2×6), did not equal the moments in the other direction. Hence,

$$4\tfrac{1}{2} + 5\,B = 12\tfrac{1}{2} + 12,$$

whence $B = 4$ pounds.

Since $A + B = 10$,

$A = 6$ pounds.

Chicago, Ill. L. W. DUNCAN.

Enclosed find a solution for Mr. Brode's problem in mechanics in the August number of the AMERICAN ELECTRICIAN. Let the line $A - B$ represent the plank which is sup-

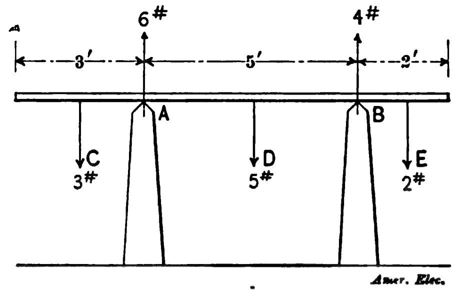

FIG. 7.—MR. DUNCAN'S SOLUTION.

ported at C and D. Since the plank is symmetrical, i. e., of uniform weight per unit length, all the weight may be considered as concentrated at G, the middle point. Substituting forces for the supports as in Fig. 8 and rotating the beam about A, making the summation of all the force clockwise

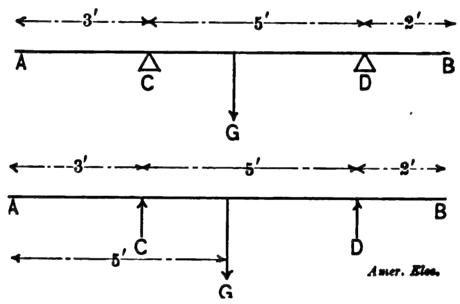

FIG. 8.—MR. CUMMING'S SOLUTION.

equal the summation of all the forces counter clockwise because the beam is in equilibrium, we obtain

$$5\,G - 3\,C - 8\,D = 0.$$

Revolving about C gives

$$5\,G - 2\,D - 7\,C = 0.$$

The summation of the vertical forces $= 0$ gives, using upwards as positive,

$$-G + C + D = 0.$$

This gives three simultaneous equations of the first degree, from which is obtained by simple algebra,

$$D = 4 \text{ and } C = 6.$$

Devil's Lake, N. Dak. F. J. CUMMING.

Enclosed herewith is my solution of Mr. Brode's problem in mechanics. Taking moments of the forces about the point F_1, in

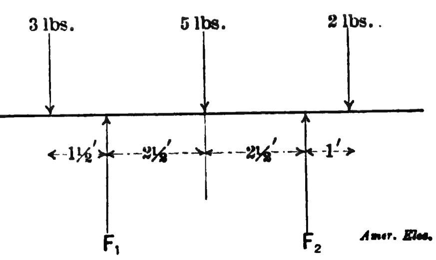

FIG. 9.—MR. SWEETNAM'S SOLUTION.

Fig. 9, we find the reaction, F_2, from the equation

$$(3 \times 1.5) - (5 \times 2.5) + (F_2 \times 5) - (2 \times 6) = 0,$$

$$5\,F_2 = 20,$$

$$F_2 = 4,$$

whence $F_1 = 6$,

Elkhart, Ind. A. H. SWEETNAM.

Questions and Answers

Inquiries not accompanied by the name and address of the inquirer, will not receive attention.

Where can I buy armature punches for small direct-current motors? J. I. H.

From Wilson & Smith, 44 Vine Street, Worcester, Mass.

Why does a three-phase induction motor change its direction of rotation if any two leads are transposed? E. P. C.

Because the direction of the rotating field is reversed owing to the transposition of the two stator circuits.

What is the formula for converting copper wire cross-section from metric measure to circular mils and *vice versa?* G. W.

The diameter in mils is equal to the diameter in millimeters multiplied by 39.37. The diameter in millimeters is equal to the diameter in mils multiplied by 0.02539. Having found the diameter, it is easy to deduce the area in the units in which you are working.

How can I control the speed of an alternating-current motor driving a dental lathe, so as to obtain 1600 r.p.m., 2000 r.p.m., and the present speed of 3400 r.p.m.? The circuit is 104 volts and 60 cycles. W. G. H.

If the motor is of the commutator variety with the field winding connected in series with the armature, it is only necessary to connect resistance in series with the machine in order to control its speed. If it is an induction motor it will have to be sent to the manufacturers to have the speed control applied.

If a motor be coupled to a dynamo of the same voltage and brought up to speed by current from an outside source; and if the dynamo be adjusted to produce the voltage required by the motor and the latter be switched from the outside source to its own dynamo, will the machines continue to run, the dynamo supplying the current for the motor and the latter driving the dynamo? S. K.

Certainly not. Even if there were no internal loss in the windings of the two machines the friction in the bearings would prevent them from running without power from an external source; the internal losses make it still worse.

Is it necessary to ground the neutral wire of a three-wire system? (2) What is the advantage of the neutral ground? (3) Should the conduit of a conduit wiring installation be grounded? W. H. H.

It is not necessary, but the Underwriters recommend it. (2) The maximum e.m.f. to which a person may be subjected while standing on the ground or any grounded metallic structure is limited to the voltage between the neutral wire and one of the outside wires, whereas with an ungrounded neutral, if one of the main wires became grounded accidentally, contact with the other one would give the full voltage of the system. (3) Yes.

What is the best way to demagnetize a watch? H. S. W.

Mount the watch in a revolvable frame in front of one pole of a powerful electro-magnet arranged to be excited with direct-current. Revolve the watch at a high speed and then turn on the current gradually. After ten or fifteen seconds turn the current off gradually and take the watch out of the frame. If alternating current is available the watch need not be revolved, but may be held stationary in front of the magnet pole. In this case the magnet must have either a laminated core or none at all.

How can the correct running speed of a direct-current dynamo of known voltage be determined when there is no source of power available to drive the machine except a direct-current circuit? E. F. H.

Drive it as a motor from the supply circuit, being careful to use ample resistance in series with which to prevent it running at excessive speed in case it should be designed for a voltage lower than that of the circuit. If the voltage of the machine coincides with that of the circuit all of the starting resistance should be cut out, of course, letting the machine run at full speed. The speed as a dynamo should be about 10 per cent higher than the speed at which it runs as a motor.

Does a turbine water-wheel have the same power located at the top of the penstock, with a draft tube extending down to the tail water, that it would have if it were located at the bottom of the penstock with all of the weight of the penstock water on top of it? C. F. K.

Yes, provided the draft tube is absolutely air-tight. The volume of water in the draft tube has the same effect on the wheel as though it were on top of the wheel instead of beneath it. For example, if you assume that the water initially drops away from the wheel, this would form a vacuum between the water and the wheel and the "sucking" effect would be the same as though the mass of water in the draft tube were on top of the water wheel.

What is the most economical apparatus for operating series arc lamp circuits from a constant-potential, alternating-current source? (2) What apparatus of that class is easiest to maintain in running order? (3) Why are motor-generators not used for this purpose? T. E. G.

It depends on local conditions entirely; no general recommendation is possible. Both constant-current transformers and reactive regulating coils give satisfaction; the former has the advantage that the total secondary e.m.f. may be anything one chooses, whereas with the latter, the maximum secondary pressure is necessarily less than that of the constant-potential source. (2) Usually the automatic reactive regulator requires less adjustment and attention. (3) They are; their first cost and relatively low efficiency compared with either a transformer or a reactive regulator, however, prevent their general use for this purpose.

How can the windings of alternating-current fan motors be changed for different frequencies? (2) If the field of a direct-current motor is weakened and its speed therefore increases, does the armature take more current than before? (3) How can I tell whether an alternator is a three-phase or a three-wire, two-phase machine without testing with instruments of any kind? The machine has three collector rings. (4) Why are rotary converters sometimes provided with a compound-wound field? (5) I understand that the series field is never used in practice; is this true? W. H. S.

You cannot do so unless the stator is of the slotted-ring type, and even in that case it would be rather difficult. The winding would have to be changed so as to increase the number of poles in direct proportion to the increase in frequency. (2) Yes; provided the backward torque of the load remains the same or increases. (3) So far as we know there are no two-phase alternators with three collector rings. There are only two standard constructions; in one four rings are connected symmetrically to points in a closed armature winding, and in the other there are two distinct armature windings, each one connected to one pair of rings. A machine with three collector rings is either a three-phase alternator or a monocyclic machine. (4) and (5) The compound winding is used for regulating purposes; it may be left cut out in some instances, but that is not the intention of the manufacturers, of course.

What is the difference between the armature and field windings of a constant-potential generator and those of a constant-current generator. (2) What effect does line loss or drop in voltage have on shunt-wound and series-wound motors operating on the same circuit? (3) What is meant by a right-hand and left-hand armature winding? (4) Does it make any difference whether the exciting current enters at the inner or outer terminal of a field magnet coil or at which end of the bobbin, provided the current travels around the core in the proper direction? (5) In an electric locomotive with series-parallel control, operating on a 250-volt circuit, the voltage at the terminals of each motor is 125 when in series and 250 when in parallel; is the current when in series double the current when in parallel, or the contrary? (6) Does the starting resistance of a shunt-wound motor affect the voltage or the current of the machine, and is the effect the same in series and compound-wound motors? S. T. W.

There is not necessarily any difference in the armature windings, but the field windings are entirely different. The constant-potential machine is provided with either a shunt field winding or both shunt and series field windings, whereas a constant-current machine is provided with a series field winding only. (2) It reduces the speed of a series-wound motor almost in proportion to the drop in voltage; the speed of a shunt-wound machine is also reduced, but not to the same extent, because the lower voltage weakens the field, and this tends to keep the speed up. (3) A right-hand winding is one which if traced from a given commutator bar works progressively around the armature clockworks; a left-hand winding is of the opposite character. (4) No. (5) It depends entirely upon the load and speed; there is not necessarily any definite relation. If the machine were standing still and thrown on the line without any preliminary gradation the current with the motors in parallel would be four times that with the motors in series, but when the machine is running, the increase of current is not nearly so great because the change is made gradually and the machine speeds up. (6) The resistance affects the voltage at the terminals of the motor and this, of course, affects the current flow. The effect is the same in all types of direct-current motor.

SUCTION GAS PRODUCERS.

Producer gas power plants are built for generating out of a suitable fuel a mixture of carbon monoxide and hydrogen, which, if used in gas engines, permits an exceedingly advantageous utilization of the fuel. Much of the producer gas is made in what are termed "pressure gas producers" by evaporating water in a separate boiler and by leading the steam mixed with air by means of a steam jet, blower or fan through the glowing fuel, whereby the steam is decomposed to hydrogen and the coal burned to carbon monoxide. This mixture of combustible gases is led through a scrubber to a gas holder and thence to the engine.

The Nagel gas producers have been designed with a view to superseding this form

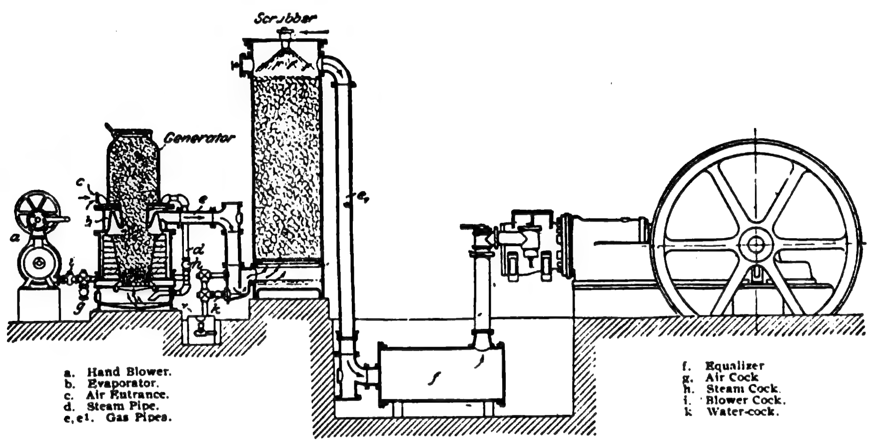

FIG. 1.—SUCTION GAS PRODUCER PLANT.

of gas producer. In this system air is drawn by the sucking action of the engine over hot water or steam, thence through the fuel bed, where it is converted into power gas, whence, after suitable purification, it passes to the engine. In the suction gas producer plant the boiler is supplanted by an evaporator, which in small plants is built on top of the producer and in large plants near the producer in the form of a tubular evaporator. This evaporator generates the steam required and utilizes the heat of the producer and of the gases. Hence it possesses an advantage over the older system, which requires the firing of a separate boiler.

A complete suction producer plant consists of a producer, an evaporator, an overflow water pot, a scrubber and an equalizer. The producer is provided with a hopper through which fuel can be filled into the producer without interfering with the working of the engine. Plants up to 25 horse-power in capacity are provided with a simple hopper so as to contain sufficient fuel for a working day. Plants above 25 horse-power and under 75 horse-power are provided with a bell hopper so as to insure a continuous running of the engine during the time of recharging. Plants above 75 horse-power are provided with an independent evaporator.

The operation of a producer plant may be followed from Fig. 1. Before starting the engine the fuel in the producer is caused to burn rapidly by means of a small hand blower, *a*, until the gas is burning well. This operation requires about ten minutes, after which the hand blower is stopped and the engine started in the usual way. The engine now draws by its own sucking action the necessary amount of air, thereby producing its own power gas. The air enters at *c* and goes through the evaporator *b*. Here it is saturated with steam and the mixture of air and steam passes through *d* under the grate of the producer through the fuel, through pipe *e* to the scrubber, and thence to the equalizer tank *f*, which is directly connected to the engine. The gas-making process continues so long as the engine is moving.

As the engine makes producer gas according to its load, it is claimed that only such an amount of air and steam is drawn through the producer as is necessary for generating the amount of gas required. At low loads less gas is made, and the whole system being under negative pressure, it is claimed that no gas can leak into the atmosphere. The only attention required by the plant is to fill the producer from one to four times a day, according to the size, and remove the ashes twice a day. The coal consumption is said to be regulated automatically and to be independent of the skill of the attendant, which is of undoubted advantage. Anthracite coal, charcoal or coke can be used for generating gas in the producer. It is estimated that 1 to 1¼ pounds of anthracite coal or charcoal or 1⅓ to 1½ pounds of coke are required to develop one horse-power-hour. The producers are made by Dr. Oskar Nagel, of New York City, and are built in sizes from 5 to 300 horse-power and over.

WESTINGHOUSE TYPE H POLYPHASE INDUCTION MOTOR.

The Westinghouse type H motor is designed for constant speed service and belongs to that class of induction motors without contacts or any connection whatever between the supply circuit and the rotating element. The starting mechanism is mounted on the shaft external to the frame, and consists of a device by means of which resistance is inserted in the winding of the revolving part when starting and gradually cut out as the speed increases until the winding is short-circuited. Thus by a gradual development the starting current becomes practically the running current, which is a very important feature on small systems where a constant voltage is essential and which would be considerably affected by throwing the motor suddenly on the line. The frame of the motor is a solid ring of cast iron with feet for supporting the machine. Slide rails may be used or not as desired. The core carrying the stationary windings is built up of steel punchings which fit the bore of the frame and which are firmly held together between two iron rings. Substantial brackets carrying the bearings for the rotating element are bolted to the cast iron frame, and may be fastened in four positions, permitting the motor to be mounted on the floor, side wall or ceiling, and the oil reservoirs to always be in the proper position. By means of oil rings revolving in the reservoirs copious lubrication is provided for the motor while in operation. To secure the starting characteristics above mentioned the secondary windings are similar to those of a polyphase generator. Insulated copper bars are inserted in the partially closed slots in the steel punchings of the rotor. These punchings are mounted on a cast iron spider which is keyed to the shaft. The overhanging tips of the teeth hold the bars in the slots. The end connectors are secured to the bars after they are in place and the leads are brought out through the hollow shaft to contacts in the starting device. This consists of a resistance which is cut in and out of the circuit by a sliding contact, and is so arranged that as the motor accelerates it may be gradually cut out

FIG. 1.—WESTINGHOUSE TYPE H INDUCTION MOTOR.

by pushing in the cylinder, until for normal running the winding is short-circuited. The starting device may be operated by a lever rigged in a manner similar to an ordinary belt shifting device. The case of the starter is a cast iron cylinder of enclosed construction, and, being dust-proof and sparkless in operation, may be used with impunity in the presence of inflammable vapor or dust-laden air. These motors are built for two and three-phase circuits in sizes from 5 to 50 horse-power, for 3000 and 7200 alternations. Standard voltages are 100, 200 and 400 for machines up to 20 horse-power, and 200 and 400 volts from 20 to 50 horse-power.

New Apparatus and Appliances

A NEW LINE OF SMALL POWER MOTORS.

The application of electric motors to general power purposes involves so many different conditions that motors for successful general use must now possess, to a large degree, all those qualities which hitherto have been considered necessary only in motors intended for special severe service. This idea has been followed closely in the design of the new line of General Electric Company's small CQ motors. They are built in sizes ranging from ¼ horsepower to 20 horsepower, and are adapted to practically all conditions of service, as their design has been laid out with special reference to simplicity and durability in constructon and reliability in operation. The customary form of bearing support for small motors is here utilized, but with some attention paid to appearance as well as strength and rigidity. The end shields are simple in form and of large section, giving rigidity to the frame. They may be rotated in either of four positions differing 90° from each other to meet the requirements for various positions of installation. The bearings encased in the end shields are lubricated by oil flooding rings revolving in the oil reservoir below the shaft. The linings are single castings of hard composition of ample bearing surface. The general form of the motor secures a low centre of gravity of the complete motor and a short magnetic circuit, which, combined with high-grade workmanship, gives the CQ motor a notable efficiency for its capacity and enables the maker to produce a compact machine free from vibration. The cylindrical soft cast steel magnetic yoke is provided with feet which allow rigid connection with the support of the motor. The pole pieces are separate from the yoke and fastened to it by through bolts, permitting ready removal when repairs are necessary. The extended tips of the pole pieces hold the field coils rigidly in position. One evidence of the care used in the design of these motors is to be found in the construction of the armature. The armature body is insulated in a manner similar to that employed in the standard General Electric railway motors. The insulation is tough and impervious to moisture and practically indestructible. Thorough tests of the insulation of the copper wire coils are made before placing them in slots punched in the armatture disc in

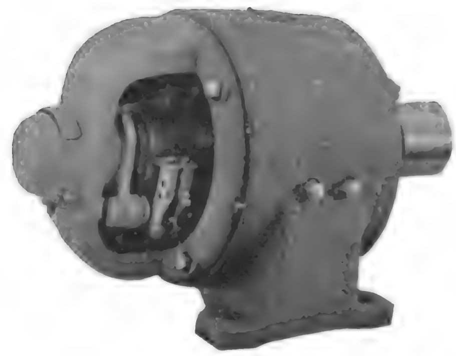

FIG. 2.—GENERAL ELECTRIC "CQ" MOTOR.

which they are retained by steel binding wires. The arrangement of the windings in the slots is such that a large surface of copper is provided in the position best calculated to dissipate the heat and ensure cool running and high efficiency. In the larger sizes air ducts are provided for ventilating the cores and windings. The steel laminations are clamped rigidly between two cast iron spiders or end plates which have flanges to support the extended ends of the armature coils. The motors operate with practically no sparking under variations from no load to full load and without shifting the brushes. The speeds of the CQ motors have been chosen to permit direct belting to line shafts running at ordinary speeds without the use of intermediate countershafts. It will be recognized that the chief advantage of slow speed in electric motors is the reduction of losses due to belt wear on bearings and commutator, but it must be borne in mind that a decrease in speed must necessarily reduce the output of a motor for a given size and weight of material. When a lower driving speed is desired than can be obtained with a standard CQ motor, a belt tightening apparatus is furnished which allows a driving pulley smaller than the standard one to be used and at the same time secures sufficient contact to enable the full power of the motor to be transmitted. This is particularly serviceable when a very short driving belt must be used. The loose pulley may be adjusted to any lead of the belt and in many cases avoids the adoption of a gear drive when it is undesirable.

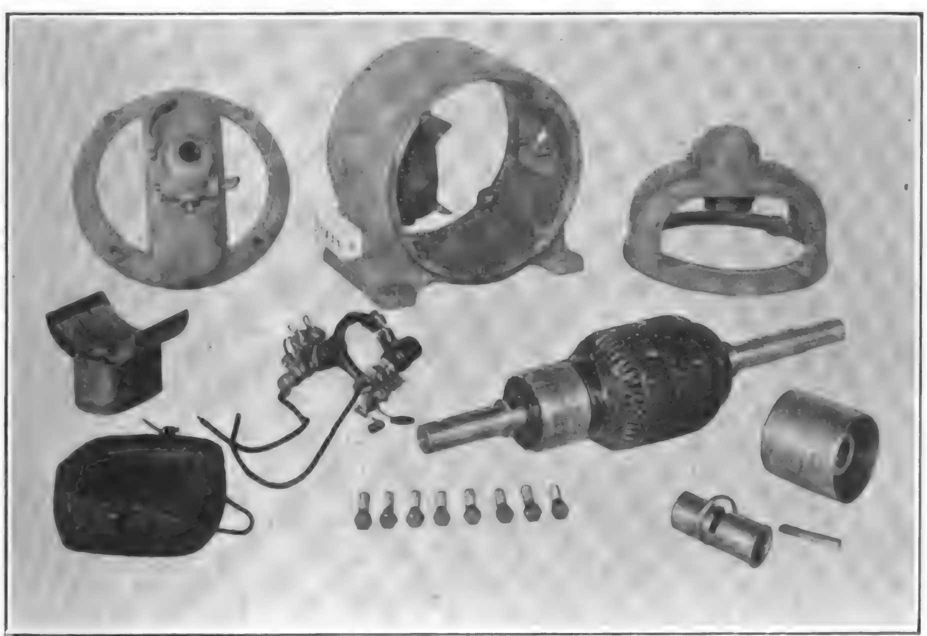

FIG. 1.—GENERAL ELECTRIC "CQ" MOTOR DISASSEMBLED.

THE UNIVERSAL DIRECT-CONNECTION PANEL.

Among the many annoying details of the interior wiring business, the troubles due to panel boards are, perhaps, the most difficult to overcome. It is evident that the panel is the most conspicuous part of a concealed-wiring installation, and that the use of make-shift apparatus for this portion of the equipment should not be tolerated. To procure a suitable panel from the manufacturer, frequently involves a delay in the completion of the undertaking, because it is almost out of the question for a single dealer to keep on hand a complete stock when the requirements of the various installations are so essentially different. The universal direct-connection panel, illustrated herewith, has been designed to eliminate the trouble mentioned above. This panel can be used for two-wire or three-wire work, with plug, link or enclosed fuses. Each tablet being adaptable in this way, it is only necessary for the contractor or dealer to have on hand a few sizes of fuses and switch panels to be certain of supplying from the stock exactly the board required. In addition to this feature these boards are claimed to be smaller than any other ap-

FIG. 3.—SIX-CIRCUIT TABLET.

proved tablet at present to be found on the market. In the construction of these boards, the circuit terminal of the switch base is carried over the bus-bar and formed into a fuse plug receptacle, so located that the fuses make direct connection with the

bus-bar. By this means the bus-bars are covered by the branch bars, and an accidental short circuit involving the mains is practically impossible. When the fuses are removed all the exposed metal work except the main terminals is disconnected. This panel is manufactured by Johnson & Morton, Utica, N. Y.

"COMMERCIAL" INDUCTION MOTORS.

The Commercial Electric Company, Indianapolis, Ind., is placing on the market a line of induction motors, in the design of which the services were retained of Mr. H. M. Hobart, of London, the well-known authority on induction motor design. The

FIG. 4.—COMMERCIAL INDUCTION MOTOR.

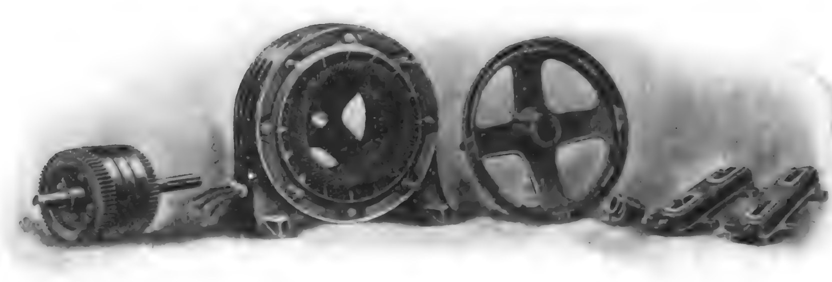

FIG. 5.—INDUCTION MOTOR DISASSEMBLED

details of this motor are illustrated in Fig. 5 and the complete motor is shown in Fig. 4. It is well known that in order to produce a high power factor in induction motors it is essential that there shall be a limited clearance between the rotor and stator. In the present motor the design of the stator frame and stator head is such that an equal division of this clearance is always secured and maintained, it being an impossibility to assemble the machine in such a manner as to give the rotor an unequal air-gap on opposite sides. In order to reduce the wear of the rotor shaft to a minimum, very large bearing surfaces have been provided. The bearings are also so designed that if the operator should flood them with oil no damage to the machine could occur. The bearing linings are duplicate and interchangeable; thus, it is claimed, making the replacement of the bearing a much more simple and less expensive matter than is involved in the accurate readjustment of "adjustable" bearings. The shaft is accurately ground to gauge, the bearings are polished and the rotors are mounted on the shaft by means of hydraulic pressure. Ventilating apertures are provided across the faces of the stator and rotor cores, thereby causing a free circulation of air and insuring cool operation. The motors are manufactured in all standard ratings from 5 horse-power to 200 horse-power. A line of small single-phase self-starting induction motors is also made in ratings from 1 horse-power to 5 horse-power. The machines are made for all standard voltages for both two and three-phase circuits and for frequencies of from 25 to 60 cycles.

CEILING ROSETTE WITH ENCLOSED FUSE.

Fig. 6 herewith shows a view of the General Electric Company's ceiling rosette

FIG. 6.—CEILING ROSETTE WITH ENCLOSED FUSE.

which has several points of interest. This rosette has been especially designed for 250-volt work. It takes enclosed glass tube fuses. Its appearance is similar to that of the other rosettes produced by this company, and like them it has substantial porcelain parts and punchings. There is ample space in the cover for the knot in the flexible cord, so there is no danger of the lamp falling. The opening in the cover permits of the use of standard reinforced flexible cord. The clips receiving the enclosed glass tube fuses are strong and durable.

LARGE CONTROLLER.

Fig. 7 herewith is said to illustrate the largest capacity electric motor controller ever built, it being one of two designed and constructed by the Cutler-Hammer Mfg. Co., of Milwaukee, for the Carnegie Steel Co., of Pittsburg. The panels are of white Italian marble, their total dimensions being 11 feet long and 7 feet 8 inches high.

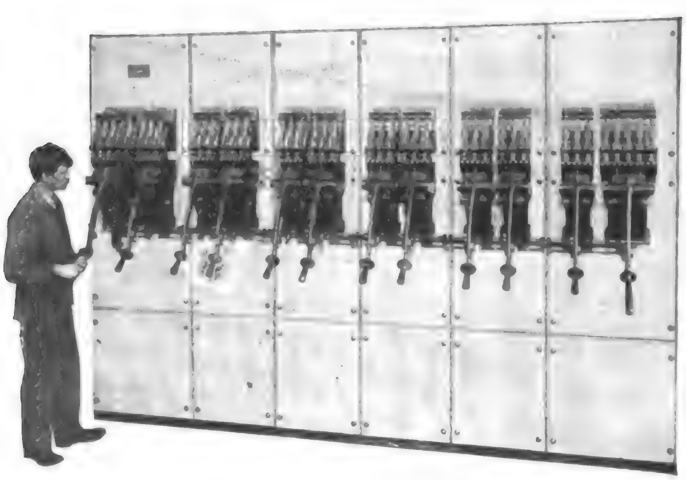

FIG. 7.—LARGE CUTLER-HAMMER MOTOR CONTROLLER.

The first and last switches have a continuous capacity of 10,000 amperes, and the intermediate switches a continuous capacity of 6000 amperes. The levers with which the switches are operated are a trifle over three feet long, but by means of a toggle joint action they can be easily thrown into contact. Before these two controllers were built there was but one extra large capacity controller in the United States, that being installed over a year ago in the plant of the Pittsburg Reduction Company at Massena, N. Y. The resistance for these starters is composed of steel rails arranged in a rack 19 feet high, 30 feet long and 14 feet wide.

AUTOMATIC NUMBERING MACHINE.

In the new model of automatic numbering machine brought out by The Bates Machine Company, of New York City, the customary iron or brass frames and cases are superseded by steel. It is only necessary to move the indicator until the word representing the class of numbering desired appears in the window of the front plate. When set "Consecutive" the number advances from 1 to 999,999, changing all the wheels automatically. When set "Duplicate," each number is printed twice and is then advanced consecutively. When set "Repeat" the automatic mechanism is detached and the number is repeated continu-

123456

FAC SIMILE IMPRESSION

FIG. 8.—NUMBERING MACHINE.

ously. Only the standard size and style of figures, shown under the illustration, are furnished in the stock machines. Drop-ciphers with their springs and pins have been eliminated, and the wheels themselves

are made depressible to provide the necessary spaces preceding the unit wheel. The plunger, which is made of Bessemer steel, is shielded from view when in its normal position. The figures are automatically inked before each impression from a thick felt pad, the padholder of which may be instantly removed from the machine for re-inking. An accurate gauge plate assures printing precisely upon a line.

AUTOMATIC ENGINE STOP AND SPEED LIMIT.

The Locke Regulator Company, of Salem, Mass., has placed on the market an automatic engine stop and speed limit system which is illustrated herewith. The main shut-off valve is actuated by the auxiliary electric valve shown in section by Fig. 9. The purpose of this valve is to pro-

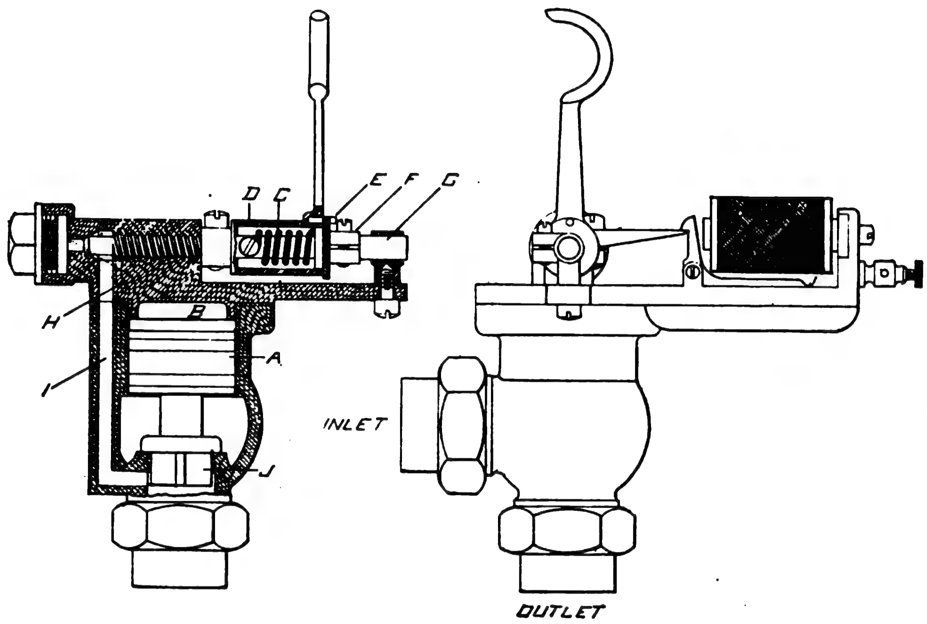

FIG. 9.—LOCKE AUXILIARY ELECTRIC VALVE.

vide means of shutting off steam from convenient points electrically or automatically by the speed limit whenever the speed increases above normal. For this purpose a balance valve is used with a cylinder and piston at one end; whenever steam is exhausted from the top side of the piston by the electrically actuated auxiliary valve, the piston is forced to the upper end of the cylinder by the steam pressure, thereby closing the main valve. The only adjustment necessary after closing is to latch the auxiliary valve. When this is done the pressure above the piston will become equalized, allowing the main valve to be forced open to its normal position by the steam acting on the differential poppits. The operation of the auxiliary valve shown in Fig. 9 is as follows. Steam enters at the side of valve marked inlet, passes above piston *A* and fills space *B*. Whenever the valve is electrically tripped, spring *C* uncoils, rotating spring barrel *D*, which carries pin *E*. This pin strikes cam *F*, which is clamped to the auxiliary valve spindle *G*, which rotates one-fourth of a turn, removing the valve from its seat 1/16 inch and exhausting steam from space *B* through passages *H* and *I* to the outlet end of valve. As piston *A* is larger than poppet *J*, the poppet will be forced open, allowing steam to pass through the valve. This in turn exhausts steam from the top side of the piston of the main shut-off valve, closing the same. The object of the speed limit governor is to automatically close an electric circuit whenever the engine speed increases above the normal, thereby tripping the electric device of the main shut-off valve, closing the same. For this purpose the Pickering style of governor is used, which is designed to be belted to the engine shaft and connected in wiring circuit as any ordinary push button would be.

NATIONAL ELECTRICAL CODE STANDARD ENCLOSED FUSES AND CUT-OUTS.

The General Electric Company is now furnishing a complete line of National Electrical Code standard enclosed fuses and cut-outs, ranging from 3 to 600 amperes for both the 250 and 600 voltages. The cut-outs and fuses are uniformly compact and durable, and the insertion or removal

FIG. 10.—250-VOLT, 31-60 AMPERE FUSE.

of the fuses is easy and safe. For fuses rated from 3 to 30 amperes, 250 volts, cut-outs similar to the Edison plug cut-outs are furnished, and for fuses from 31 to 60 amperes, 250 volts, two and three-wire, main-line and single-line cut-outs are supplied. All other sizes of fuses are pro-

FIG. 11.—250-VOLT, 65-100 AMPERE' FUSE.

vided with single pole cut-outs. With all cut-outs are used the G. E. wrought copper cable terminals, with the exception of the 30-ampere, 250-volt sizes. These are provided with washer and screw terminals. The fuses are of the well-known enclosed-fuse type, ferrule or knife-blade contacts being used, according to the requirements of the code. The knife-blade type, in addi-

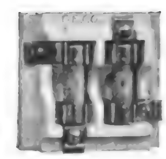

FIG. 12.—TWO-WIRE, CROSS-OVER, 250-VOLT, 3-30-AMPERE CUTOUT.

tion to the standard parts, has a brace placed in each end of the tube to engage

FIG. 13.—250-VOLT, 30-AMPERE RENEWABLE FUSE PLUG.

the screws which hold the end caps in place. The brace is rigidly attached to the contact blades. This forms a strong mechanical

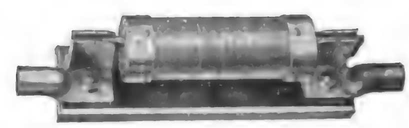

FIG. 14.—SINGLE-POLE, 600-VOLT, 401-600-AMPERE CUTOUT.

joint which does not depend solely upon the shearing strength of the fibre tube. The knife blade contacts are of punched

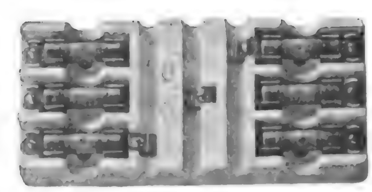

FIG. 15.—THREE-WIRE, DOUBLE-BRANCH, 250-VOLT, 3-30-AMPERE CUTOUT.

copper, and when used with the standard switch clips provide the best form of contact. The parts being copper, of high con-

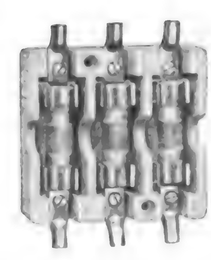

FIG. 16.—THREE-WIRE, MAIN LINE, 250-VOLT, 3-30-AMPERE CUTOUT.

ductivity, generously proportioned, the heating is reduced to a minimum. In the ferrule type the contacts are made of phosphor bronze clips designed to give the utmost contact and elasticity in the smallest

possible space. The renewable fuse plug consists of a brass tube, with the lower end threaded to fit the standard screw shell, and the upper part insulated by a porcelain shell. There is also in the upper end, a spring clip which receives the ferrule contact of the reload, the ferrule on the other end forming the center contact of the plug. The reloads are the 30 and 60 ampere, 250-volt enclosed fuses.

RECEPTACLE FOR MOULDING WORK.

This receptacle for moulding work recently put on the market by the General Electric Company has a number of commendable features. The terminals are concealed, preventing possibility of a short circuit and adding largely to the attractiveness of its appearance. It is so arranged as to be adaptable for a shade holder. There are no live parts on the back, and the cover and base are held firmly by two screws to the surface to which it is attached.

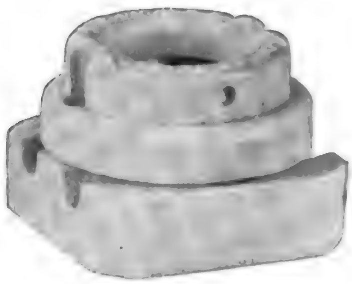

FIG. 17.—RECEPTACLE.

MODEL FLANGE CLAMP.

The clamp shown herewith has been brought out by James McCrea & Co., of Chicago, Ill., for repairing leaks in steam pipes under pressure when it is impossible to shut down and renew the packing. The mechanism may be thoroughly understood by reference to Fig. 18. The clamp consists of an outer ring made in two sections, in which the compression screws are placed; an inner or compression ring made in four sections, with a lug on each section to correspond with a slot in the outer ring, thus assuring no displacement while attaching. A gasket accompanies the outfit which is placed around the flanges over the leak. Should, by any reason, the leak appear around the bolts holding the flanges tother, it is an easy matter to pack around the bolt with a little hemp soaked in red or white lead, and use a common iron washer.

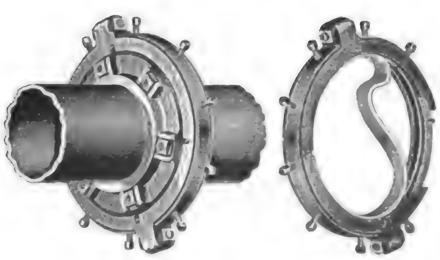

FIG. 18.—FLANGE CLAMP.—FIG. 19.

CURTIS STEAM TURBINES IN JAPAN.

With the industrial awakening of Japan has come a need for electric power for manufacturing, transportation and lighting. Japanese engineers are wide awake, and their enterprise is nowhere more clearly indicated than in their adoption of steam turbine electric generating units.

On July 29, 1904, the first shipment of steam turbines arrived in Japan via the steamship *Korea*, from San Francisco. They were of 500 kilowatt capacity, of the Curtis type, and were for operating the Shigai Railway in Tokio. Four weeks from their arrival they were in full operation. As significant of the success of these units, there have been ordered by the Japanese from the General Electric Company of New York, thirty-seven Curtis steam turbines with electric generators with a total normal capacity of more than 35,000 horse-power. Of these, eleven units are now installed and in satisfactory operation.

AMERICAN DYNAMOS IN AN ORIENTAL PRINTING HOUSE.

The accompanying engraving shows a portion of the power plant of Bureau of Public Printing at Manila, P. I.

The plant includes two standard 50-kilowatt Crocker-Wheeler electric generators. One was installed last year and the other in 1901. It is significant of the simple design of these machines that they are operated by natives whose mechanical experience seldom comprehends anything more intricate than a wooden plow. The native shown in the picture is quoted by Mr. Tatum, the engineer in charge, as saying, "Me saber Crockerne-Whelem electricidad maquina." ("I know all about Crocker-Wheeler electric machines.")

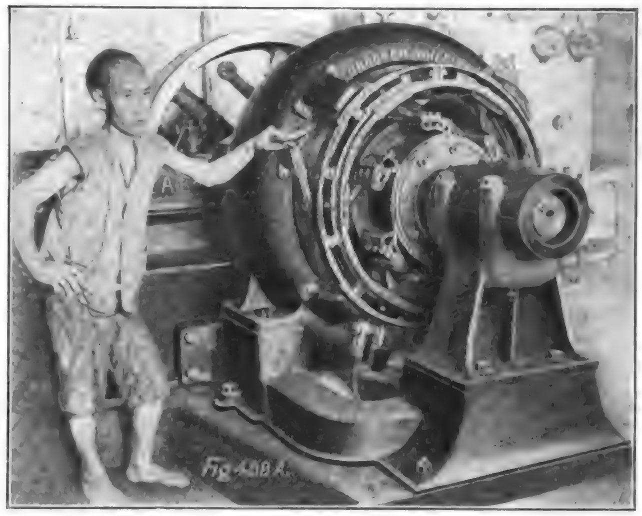

FIG. 1.—GENERATOR IN MANILA PRINTING OFFICE.

ECONOMY IN LUBRICATION.

Economy in the use of lubricating oils is a matter of no mean importance in a central station or other power plant, the total cost of lubrication being usually the largest of the subordinate items. The attention being given nowadays to this feature of power plant economy is indicated by the careful arrangement of lubrication details in some of the modern installations of large size. For example, the Lackawanna Steel Company, of Buffalo, N. Y., is equipping its power plants to obtain the utmost economy in oil handling and consumption. At these mills there are installed 48,000 horse-

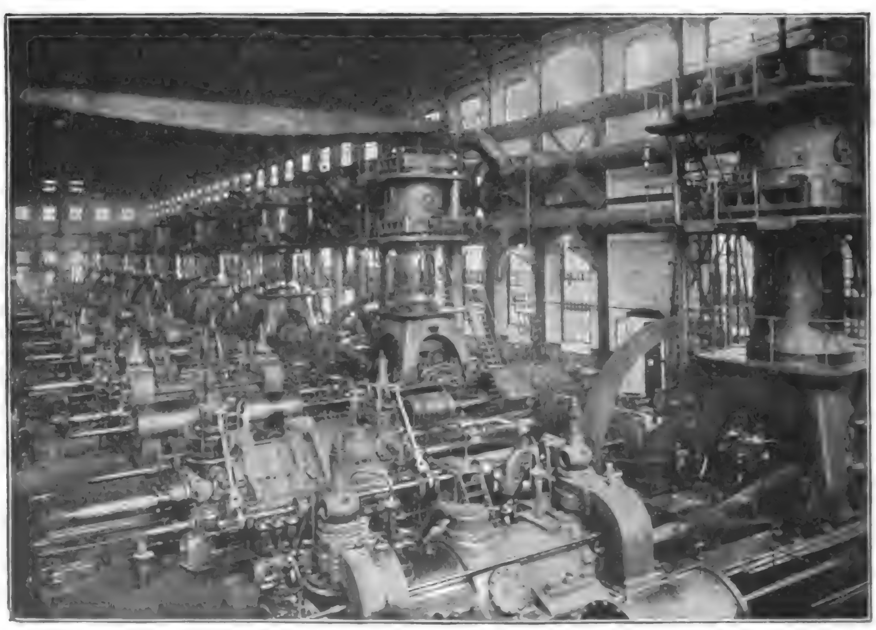

FIG. 2.—LACKAWANNA STEEL COMPANY'S POWER STATION IN BUFFALO

power of engines; five Allis-Chalmers vertical cross-compound steam engines aggregating 16,000 horse-power, drive roll trains, etc., and sixteen blowing engine units are driven each by a 2,000-h.p. Koerting gas engine. The accompanying illustration shows the interior of one of these plants.

The complete power installation of 48,000 horse-power is being equipped with the "White Star" continuous oiling system, manufactured by the Pittsburg Gauge & Supply Company, of Pittsburg, Pa. By this system the oil is distributed continuously to all bearings, keeping them constantly supplied with just the amount of oil required for best results. All drips and used oil are drained away to a "White Star" filter, which constitutes a prominent feature of the system. In the filter it is cleaned of all impurities and is then pumped to a storage tank, whence it is returned to the lubricating circuit. Loss of oil is said to be entirely avoided, the only means of escape from the system being by leakage due to excessive wearing of the bearings.

As an indication of the merits of such a system it is interesting to consider the case of the Union Steel Company's power plant. About two years ago this plant, which is located at Donora, Pa., was equipped with the "White Star" system. Previous to this installation, a 38 and 75 by 60-inch twin tandem compound condensing engine of the Porter-Allen type required an average of 1,050 gallons of engine oil per month. The application of the "White Star" system is said to have reduced the consumption to an average of 503 gallons under similar conditions—a saving of more than 52 per cent. In this same plant, on two 30 and 60 by 48-inch engines, the oil consumption is said to have been reduced from 400 gallons to 195 per month, operating full. As a further item of saving directly creditable to the "White Star" system, the services of three oilers required under the old regime were dispensed with from the start.

NEW BOOKS.

STEAM TURBINES. By Dr. A. Stodola. New York: D. Van Nostrand Company. Cloth; 434 + xvi pages, 6 ins. x 9 ins.; 241 illustrations. Price, $4.50.

The size and scope of this book preclude anything like a comprehensive review. It is a translation by Dr. Louis C. Loewenstein of the second edition of the work, which was originally published in German. The author discusses, in the sequence given, the Elementary Theory of the Steam Turbine; the Theory of the Turbine Thermodynamically Considered; the Construction of the Most Important Turbine Parts; Steam Turbine Types, and Special Problems of Turbine Theory and Construction. There is also an appendix on The Future of the Heat Engine, in which are discussed the entropy diagram for steam; the economy of the heat engine; the practical criterion of heat utilization, and the gas turbine. Three entropy diagrams are printed on large sheets and stored in a pocket in the back cover.

ELECTRICIANS' HANDY BOOK. By T. O'Conor Sloane. New York: The Norman W. Henley Publishing Company. Flexible leather; 761 pages 4½ ins. x 6½ ins.; 556 illustrations. Price, $3.50.

This book embodies a praiseworthy effort to put in form for ready reference complete fundamental information on all practical branches of electrical engineering. The first chapter is devoted to an explanation of the elementary mathematics necessary to any intelligent study of engineering principles; the author next takes up "Electric Quantity and Current"; then "The Electric Circuit," "Ohm's Law," "Electrochemistry," "Primary Batteries," "Storage Batteries," "The Magnetic Field of Force," "Magnets," "Induction," in the sequence named. Then follow chapters on the principles of direct-current machinery, alternating-current phenomena and machinery, care of dynamos and motors, and explanations of the principles and construction of minor apparatus, such as arc and incandescent lamps, measuring instruments, etc. While the book contains a rather unnecessary quantity of academic information, this can do no harm and the practical portion of the contents is in nowise sacrificed in order to get it in.

PERSONAL.

MR. J. R. McCOLL, until recently associate professor of steam engineering at Purdue University, has accepted a responsible position in the engineering department of the American Blower Company, Detroit, Mich.

MR. FRANCIS RAYMOND, formerly connected with the General Incandescent Arc Light Company, has been appointed the Chicago representative of the Moloney Electric Company, St. Louis, Mo. Mr. Raymond will occupy a suite of offices in the Old Colony Building.

MR. ROBERT R. LIVINGSTON, who was formerly connected with the Allis-Chalmers Co., and more recently with W. S. Barstow in electrical engineering work, has accepted a position with the Engineering Company of America and will make his headquarters at 74 Broadway, New York City.

DR. F. A. C. PERRINE, the well-known consulting engineer, has decided to go extensively into isolated plant work, covering the general engineering and operating problems of electric lighting and power development and operation. Dr. Perrine will be directly assisted in this work by Edwin H. Seaman, who will attend to the minor details.

MR. HALBERT P. GILLETTE, formerly associate editor of the *Engineering News*, and MR. GEORGE H. GIBSON, recently connected with the departments of publicity of the International Steam Pump Company, B. F. Sturtevant Co. and the Westinghouse companies, have formed a partnership as advertising engineers under the name of the George H. Gibson Co. The company is not an advertising agent in the usual sense, but conducts a firm's advertising in the same manner as would a department in the firm's own offices, the actual purchasing of space and printed matter being entirely in the client's hands. The company has opened offices in the Park Row Building, New York City.

MR. W. E. HARRINGTON has severed his connection as vice-president and general manager of the New York & Philadelphia Company and joined the forces of J. G. White & Co., of New York, as operating manager. Mr. Harrington has had an exceptionally broad experience in the engineering field, particularly in the operation of electric railway, lighting and gas properties, and as operating manager of J. G. White & Co. he will supervise all of the railway, electric lighting, gas and other properties operated by this company. Mr. Harrington is an active member of the Executive Committee of the American Street Railway Association and a member of the American Institute of Electrical Engineers. He will make his headquarters at the New York office of J. G. White & Co., 43 Exchange Place.

TRADE PUBLICATIONS.

PANEL BOXES. H. T. Paiste Co., Philadelphia, Pa.—This is bulletin No. 25, devoted to panel cut-outs, entrance switches and other specialties.

RECORDING WATTMETER. General Electric Company.—This is bulletin 4415, illustrating and describing the type C Thompson recording wattmeter.

ELECTRIC HEATERS. General Electric Company.—A pamphlet of pocket size describing the electric coffee percolater manufactured by the G. E. Company.

SECOND-HAND MACHINERY. J. H. Thompson, Jr., New York.—Bargain list No. 4 of second-hand electrical and steam machinery ready for immediate delivery.

STEAM ENGINES. Ball Engine Company, Erie, Pa.—A well-executed pamphlet of pocket size, describing the new designs of engine brought out by this company.

FLANGED PIPE JOINTS. Crane Co., Chicago, Ill.—Bulletin No. 7FJ, illustrating and describing the various styles of joints used in attaching flanges to wrought pipe.

SERVICE CUT-OUTS. General Electric Company.—Bulletin 4416, superseding bulletin 4302 and illustrating and describing the company's triple-pole service box arranged for enclosed fuses.

ELECTRIC HOISTS. General Electric Company.—Bulletin 4412 illustrating and describing the various forms of Lidgerwood-G. E. hoists for building operations and general construction work.

TOOLS. The Cleveland Twist Drill Company, Cleveland, Ohio.—A catalogue of standard size, illustrating the sets of tools designed by this company expressly for turret lathes and screw machines.

MOTORS AND DYNAMOS. The Barriett Electric Company, Cincinnati, Ohio.—Bulletin No. 4 containing brief descriptions of the various types of direct-current motors and dynamos built by this company.

MODERN VENTILATION. The Electric Ventilating Company, Chicago, Ill.—A booklet containing a brief discourse on the science of ventilation, and describing the system of ventilation controlled by this company.

ELECTRIC SPECIALTIES. — The Trumbull Electric Manufacturing Company, Plainville, Conn. A supplement describing the Type A switches, cast terminal lugs, fuse holders and extension posts made by the Trumbull Co.

VALVES. Crane Co., Chicago, Ill.—Circular No. 4SDV, describing the Crane removable spring-disc brass valves. These are made in the globe, angle and cross patterns and are suitable for working pressures up to 150 pounds.

ELECTRIC HEATERS. General Electric Company.—A small folder describing the electric flatirons of the enclosed-cartridge unit type for laundry or household use. These operate at 95 and 125 volts and consume 500 watts.

CRANE MOTORS. Sprague Electric Company, New York.—Bulletin No. 223, describing the Type N motors, which are specially designed for crane service. The bulletin is well printed and handsomely illustrated.

SMALL MOTORS. Crocker-Wheeler Co., Ampere, N. J.—Bulletin No. 60, superseding Bulletin No. 42, and describing the line of Form L motors manufactured by this company. These motors range in size from ¼ to 3 horse-power.

TURBINE PUMPS. General Electric Company.—Bulletin 4414, superseding bulletin 4409 and devoted to electrically driven turbine house pumps. These consist of Worthington house pumps direct connected to G. E. shunt-wound motors.

AUTOMATIC TELEPHONES. Automatic Electric Company, Chicago, Ill.—A reprint describing the new automatic telephone system built and installed by the Automatic Electric Company for the Home Telephone & Telegraph Company, Los Angeles, Cal.

REGULATING AND REVERSING CONTROLLERS. Westinghouse Electric & Manufacturing Company.—Circular No. 1108, illustrating and describing the Westinghouse regulating and reversing controllers for both alternating and direct-current motors.

INDUCTION MOTORS. Century Electric Company, St. Louis, Mo.—Bulletin No. 5, describing the single-phase alternating-current motors brought out by this company. These are built in sizes ranging from ¼ to 10 horse-power and for 25, 60, 100 and 133 cycles.

CABLING AND ARMORING MACHINES. Aiton Machine Company, New York.—Bulletin No. 85, illustrating and describing the four-head tandem cabling and armoring machine used for the manufacture of concentric cables of bare or insulated iron, steel or copper wire and for armoring purposes.

SINGLE-PHASE INDUCTION MOTORS. The Emerson Electric Manufacturing Company, St. Louis, Mo.—This is bulletin 3108 describing the Emerson Class 32 F A single-phase induction motors. The motors are of the condensed type with full-load automatic start and are built in sizes of ⅙ and 1/6 horse-power.

CALENDAR. Crouse-Hinds Co., Syracuse, N. Y.—A hanging calendar on the cardboard mount of which are shown pictures of the Empire State Express and the Hawley time register, one traveling at the rate of a mile a minute and the other drawing on a properly graduated chart a line one inch long for every hour that an employee works.

DIRECT-CONNECTED GENERATING SETS. Crocker-Wheeler, Co., Ampere, N. J.—Bulletins 56 and 57, supplementing bulletin 55 and describing Crocker-Wheeler generating sets. In one the prime mover is the Case engine built by the New Britain Machine Company, New Britain, Conn., and in the other the engine built by the W. D. Forbes Company, Hoboken, N. J., is used.

THREE-PHASE TRACTION SYSTEM. The Railway Electric Power Company, New York City.—A publication setting forth the characteristic features and advantages of the Ganz three-phase alternating-current traction system, with particular reference to the results obtained from its three years' use abroad. The company controls the American patents for the Ganz system.

SILVEY STORAGE BATTERY. The Dayton Manufacturing Company, Dayton, Ohio.—Bulletin No. 130, published by the Storage Battery Department of the Dayton Manufacturing Company and containing information relative to the use of the Vilvey storage battery in connection with isolated lighting plants. Diagrams of connections are given for the various Silvey systems.

COMMON-BATTERY NON-MULTIPLE SWITCHBOARDS. The Kellogg Switchboard & Supply Company, Chicago, Ill.—A handsomely executed catalogue of standard size, designated Bulletin No. 11, illustrating and describing the various types of Kellogg common-battery non-multiple switchboards and their accessories. The bulletin also contains diagrams of connections printed in two colors.

BUSINESS NEWS.

THE AMERICAN BLOWER COMPANY, Detroit, Mich., has received from the National Tube Company a large and important order for immediate execution, embracing heating equipment for the tube company's five new butt weld mills at Loraine.

THE ABBOTT ELECTRIC COMPANY, Boston, Mass., has added a supply department to its business. The company carries a line of motors in sizes ranging from 1-12 to 10 h.p., as well as rheostats, controllers, circuit-breakers, ceiling and desk fans, switchboards and storage and dry batteries.

ECONOMICAL ELECTRIC LAMP COMPANY, New York City, is bringing out something entirely new in the way of a window demonstrator which is termed a "silent salesman." This is an attractive automatic device for showing how the light may be turned up or down by using "economical" lamps.

THE RISDON-ALCOTT CO., Mount Holly, N. J., reports that it has just shipped to the Cramer Electric Company, Hailey, Idaho, an 800-h.p. turbine unit consisting of three wheels on horizontal shafts for setting in a concrete flume. These wheels are to be direct-connected to a Crocker-Wheeler generator.

THE LAGONDA MANUFACTURING COMPANY, Springfield, Ohio, reports that it has been so overcrowded with orders that it was necessary for them to run their factory all night during the greater part of the month of July. The increased work necessitated the employment of two sets of men for operating the machines and doing bench work.

CROCKER-WHEELER CO., Ampere, N. J., reports that it is in receipt of an order for a 200-kilovolt-ampere, three-phase, 60-cycle, engine-type, alternating-current generator for the Ivorydale (Ohio) lighting and power plant of the Proctor & Gamble Co. This machine is a duplicate of the first Crocker-Wheeler alternator ever built, which was installed ten months ago in the Atlanta plant of the Proctor & Gamble Co.

WORCESTER ELECTRIC MANUFACTURING COMPANY, Worcester, Mass., has recently added another story to its factory, which will give the company over 5000 square feet of additional floor space. The company manufactures a line of knife switches, switchboards, panel boards, cabinets, combination switches, fuse blocks, etc., and the additional space was greatly needed, since in order to make immediate shipments it was necessary to carry a large stock of slate and ready-to-assemble panel boards and switches.

THE MORSE CHAIN COMPANY, Trumansburg, N. Y., is building at Ithaca, N. Y., a plant of five times the capacity of the present one. The old plant was originally started for the manufacture of bicycle chains, but in 1901 the company brought out its high-speed, silent-running chain, and since that time has had a rapidly growing business. In the line of power transmission the Morse Co. has in service chains transmitting over 75,000 h.p. and is furnishing drives up to 500 h.p. for a single transmission.

CRESCENT ELECTRICAL MANUFACTURING COMPANY, Rochester, N. Y., states that it has been compelled to increase its factory space and to add new machinery owing to the demands for its products. The company has taken up the manufacture of switch and panel-boards. This department, we are informed, is in charge of one of the most expert designers and builders of this class of work in the country. The company has also added to its regular lines a number of porcelain specialties, fuse-blocks, etc.

THE CHANDLER & TAYLOR CO., Indianapolis, Ind., has recently secured contracts for its enclosed self-oiling, direct-connected engines in the following institutions: Purdue University, Lafayette, Ind.; Indiana State Normal School, Terre Haute, Ind.; Girls' Industrial School, Indianapolis, Ind.; Michigan College of Mines, Houghton, Mich. These engines are built in accordance with the recommendations of the Society of Mechanical Engineers and the American Institute of Electrical Engineers for direct-connected units.

THE PELTON WATER WHEEL COMPANY, New York and San Francisco, reports new orders as follows: Homestake Mining Co., Lead, S. D., an 800-h.p. Pelton wheel unit, direct connected to an electric generator. The Nevada Power Mining & Milling Company has contracted for an additional Pelton wheel of 3,000-h.p. maximum capacity, the wheel being direct-connected to an electric generator and operating under a head of 990 feet. This company is now installing two Pelton wheels for direct connection to 750-k.w. generators and proposes to transmit power to Tonopah and Goldfield, Nev. Through Mitsui & Co., San Francisco, an order was placed for a 500-h.p. wheel for use in an electric light station in Japan.

THE MARINE ENGINE & MACHINE COMPANY, Harrison, N. J., has removed its offices to 126 Liberty Street, New York, where they occupy the entire fourth floor. The company has recently secured the following contracts: Four direct-connected electrically controlled elevators for the Hutchins Building, Fifth Avenue and Thirty-ninth Street; eleven electric elevators for the College of the City of New York; one tandem electric elevator for building of the New Orleans railways; one electric elevator in the Hartford Building; two for the Pennsylvania Railroad Company at Long Island City; one electric elevator for the Willett Realty Company's new building, West End Avenue and Eighty-second Street, and one automatically controlled residence lift for E. W. Luster, 16 East Sixty-seventh Street.

THE PELTON WATER WHEEL COMPANY, San Francisco and New York, has just closed a contract for a water wheel installation for D. J. Aguirre & Co., of Tepic, Mexico. The head available is 174 feet, and the plant consists of two Pelton wheel units of 700 h.p. capacity each, direct connected to General Electric generators; also two Pelton wheel units for driving exciters. Sturgess oil type governors will be used. Pelton wheels are employed at the sugar plantation of Aguirre & Co., there being six wheels at present employed for driving heavy sugar rolls by means of direct connection, machine shops, electric lighting plant, etc. The company states that its export trade in Pelton wheels has largely increased in the past year, the company having made large shipments to Central and South America, Japan, and the Strait Settlements. Indications for further increase in these directions are most favorable.

THE PEERLESS ELECTRIC COMPANY, Warren, Ohio, states that among recent orders booked are the following: From the Empire Plow Company, of Cleveland, Ohio, for a 100-kw. generator and motors aggregating 110 h.p., for individual drive. The Kalamazoo, Mich., Railway Supply Company is installing 20 h.p. and 35 h.p. Peerless motors. The Southard Novelty Company, of Columbus, Ohio, has completed a model equipment consisting of a 25-kw. generator and thirteen Peerless motors. Boston, Mass., University is putting in two Peerless motors for laboratory duty, duplicating an equipment some time ago furnished the Massachusetts Institute of Technology. Printing press individual drives have recently been supplied to the United States Indian Training School at Carlisle, Pa., the Solvay Process Company, Solvay, N. Y., and the Glessner Medicine Company, Findlay, Ohio. An equipment that is attracting considerable attention is at the South Sharon, Pa., Steel Works of the Carnegie Co., where one hundred Peerless motors are being used on the conveyor system for handling steel from the rolls. The installation was designed by the Peerless Electric Company's engineers.

WESTINGHOUSE ELECTRIC & MANUFACTURING COMPANY has closed contracts with the Nelson Morris Company for nineteen Type CCL induction motors varying in sizes from 5 to 50 h.p. and totaling 410 h.p., and with the Decatur Car Wheel & Manufacturing Company, Birmingham, Ala., for eight motors of the same type. These are the latest design of induction motors which have been built by this company and have only recently been placed on the market. The Illinois Steel Company has also ordered eighty direct-current motors having an aggregate capacity of 3920 h.p. These motors are of the railway type and range from 30 to 75 h.p. The Hawaiian Electric Company, of Honolulu, has contracted for two 1200-kw., three-phase, 2200-volt, engine-type generators, two 125-kw. exciters, and seven 500-kw., oil-insulated, self-cooling transformers. The Rumford Falls Power Company, of Rumford Falls, Me., has ordered one 550-kw. and one 800-kw., alternating-current generator, which will be direct-connected to water wheels. The order from the latter company also includes two 450-h.p. variable-speed induction motors and 120 Type OD transformers for use on the distributing lines.

CENTRAL STATION NEWS

Readers are cordially invited to contribute to this department items of news relating to plants in their vicinity.

ALABAMA.

ENSLEY.—The City Council has defeated the resolution to call an election to vote on issuing bonds for a municipal electric light plant.

CITRONELLE.—The Business Men's Association of Citronelle, will consider propositions for the establishment of an electric light plant. C. W. Thomas is secretary of the association. The town has a population of 1,500.

OPELIKA.—It is reported that the capacity of the Opelika electric plant is to be increased three-fold to furnish power for the railway, and light and power to Opelika and Auburn. Capital, $300,000. It is stated that work of construction is to be commenced within thirty days.

ELBA.—The Pea River Power Company has been incorporated with a capital stock of $100,000. The company proposes to light the city with electricity and to supply current for commercial lighting, heating and power. The incorporators are Charles Henderson, H. D. Boyd, J. M. Garrett, B. W. Page, Y. W. Rainer and W. B. Perdue. The headquarters of the company will be in this city, but the plant, it is understood, will be located at some distance from here.

ARIZONA.

DOUGLAS.—The Douglas Improvement Company is reported to have decided to double the capacity of its water system and improve the electric lighting service.

ARKANSAS.

LUXORA.—Wm. Wood, of the Luxora Water & Light Company, writes that it is proposed to construct an electric light plant at a cost of $3000.

DARDANELLE.—It is reported that bonds have been sold by the city for an electric light plant and the building of the plant is to be started immediately.

JONESBORO—It is reported that the Jonesboro Improvement District will expend about $220,000 for the purchase of the water and lighting plants, and the construction of a sewerage system.

CAMDEN.—George Wilson, chief electrician of the Little Rock Railway & Electric Company, was in Camden recently installing a new 90-kw. alternator and a 15-kw. transformer, thereby producing 30 per cent more capacity than the old plant. The Camden company recently sold out to J. A. Trawick and J. A. Van Etten, of Little Rock, and George D. Rosenthal and William Hand, of St. Louis.

CALIFORNIA.

QUINCY.—The electric plant of H. C. Flournoy has been sold to Miss A. L. Gasner of this place.

OROVILLE.—The Oroville Light & Power Company is soon to commence work on a large power plant near Prentz.

UKIAH.—It is stated that bids will be received until Sept. 6 for a franchise to maintain certain electric transmission lines along public highways.

GILROY.—The citizens have voted in favor of issuing $51,000 bonds for the purpose of constructing sewers, providing water and electric lights and completing the City Hall.

ANAHEIM.—C. A. Copeland, of Los Angeles, has submitted to Council a report on improving and enlarging the water works and electric light plant. He estimates the cost at $40,000.

LOS ANGELES.—The details of the contracts let by the Edison Electric Company of Los Angeles for the equipment of Kern River No. 1 power plant include four 5,000-kw. three-phase generators, two exciters and step-up transformers for 75,00 volts and four Allis-Chalmers waterwheels, which are to be direct-connected.

MARYSVILLE.—The Marysville & Nevada Power & Water Company, it is reported, is having surveys made under the direction of Engr. Waggoner for a canal system that will irrigate many thousands of acres of land in Yuba County. At the point where the survey crosses Dry Creek, it is stated, that provision is being made for the installation of an electric light plant.

COLORADO.

DENVER.—It is stated that the Denver Gas & Electric Co. will expend about $150,000 in improvements. The company has been awarded a 5-year contract for lighting the streets with 50-c.p. lights.

CONNECTICUT.

STAFFORD SPRINGS.—Judge Reed has extended the time four months for the local electric light company to continue to do business under the receiver.

PLAINFIELD.—An electric power plant is to be built at the Quinebaug River, near the Canterbury bridge. The water power there has been examined by some railroad men who are favorably impressed towards utilizing it for trolley purposes.

DELAWARE.

DOVER.—The Harrington Light, Heat & Power Company has been incorporated with a capital of $25,000. The incorporators are Harrington and Philadelphia men.

FLORIDA.

MARIANNA.—The citizens have voted to issue $9,000 bonds to construct an electric light plant.

LAKELAND.—The Council has under consideration the question of increasing the capacity of the electric light plant, also putting same on duplicate basis, figuring on two 150-h.p. compound engines, a 100-kw. generator and a 150-h.p. boiler. W. B. Clay, Supt. Electric Light plant.

ST. AUGUSTINE.—The citizens have voted for a municipal electric light plant and extension of water works. A franchise for electric lighting was also granted to T. R. Osmond for the St. Johns Light & Power Company, which proposes to manufacture gas, electricity or other illuminants for light and power and to construct and operate electric railways.

JACKSONVILLE.—The following are the bids opened by the Board of Trustees for furnishing a motor generator set of about 300-kw. capacity; (*a*) Synchronous motor set; (*b*) alternate bid for induction motor set: Crocker-Wheeler Co., Ampere, N. J., *a* $6,925, *b* $7,600; General Electric Co., Schenectady, N. Y., *a* $6,073, *b* $5,430; Electric Machine Co.; Minneapolis, Minn., *b* $7,035; Ft. Wayne Electric Co., Ft. Wayne, Ind., *a* $5,623, *b* $5,331; Allis-Chalmers Co., Cincinnati, O., *a* $7,713; Westinghouse Electric Co., Pittsburg, Pa., *a* $6,671, *b* $5,380, and National Electric Co., Milwaukee, Wis., *a* $6,700.

GEORGIA.

COCHRAN.—This town has voted for $17,000 5 per cent. bonds for water and electric lights.

LAGRANGE.—Ludwig & Co., of Atlanta, have secured the contract to construct the municipal electric light plant for Lagrange.

CORDELIA.—John P. Emerson, an electrical engineer, is reported to be preparing plans for an electric light system in Cordelia and other places.

MONROE.—The Electric Supply Company, of Savannah, has secured the contract to construct the municipal electric light plant for about $20,000.

WINDER.—It is proposed to install at the city electric light plant a 30-kw. alternating-current generator, switchboard, etc. D. W. Robertson is superintendent.

THOMASVILLE.—The City Council is stated to have granted the Municipal Investment Company, of Chicago, Ill., and Columbus, Ga., a franchise for an electric light plant.

FORT GAINES.—Eugene E. Gaddis, Secy. Interstate Water Works & Construction Company, of Washington, D. C., which recently secured a franchise for water works and an electric light plant at Fort Gaines, writes that this company expects shortly to take bids for the construction of several water works and electric light plants. Nothing definite has yet been done.

ILLINOIS.

FREEBURG.—The Village Board, it is reported, has decided to erect a $10,000 municipal lighting plant.

SHAWNEETOWN.—A. M. Searles has received a franchise for water works and an electric light plant.

CLAYTON.—It is proposed to purchase at once a 60-kw. alternator for the municipal electric plant. I. M. Brown is superintendent.

OTTAWA.—The Ottawa Power Company has been incorporated with a capital of $5,000. Jas. A. Sheldon is one of the incorporators.

ALPHA.—The Tri-County Light & Power Company expects to extend its lines to North Henderson and Viola. W. I. Taze is manager.

BLOOMINGTON.—The Peoples Gas, Electric & Heating Company will probably rebuild its plant in the course of a year. J. N. Moncrieff is superintendent.

ROODHOUSE.—The Roodhouse Light, Heat & Power Company has been incorporated, with a capital of $30,000. Edmund C. Kreider, Sr., is one of the incorporators.

LOAMI.—The Sangamon County Light, Heating & Power Company has secured a 25-year franchise in this village. The village also contracted for five 2,000-c.p. arc lights for five years.

DIVERNON.—D. H. Garvey, Village Clerk, writes that the contract for constructing an electric light plant has been awarded to the Fort Wayne Electric Company, St. Louis, Mo., for $7,672.

WAUKEGAN.—The City Council has adopted a resolution authorizing H. Thacker, City Clerk, to procure bids for furnishing 200 5-ampere arc lamps for street lighting on a 3, 5 or 10-year contract.

EDWARDSVILLE.—The City Council has granted a franchise to the Slocum & Siegel Gas Company for erecting, maintaining and operating a gas and electric plant for the purpose of furnishing power, light and heat.

CHICAGO.—Shepley, Rutan & Coolidge are preparing plans for the enlargement of the Hyde Park plant of the Commonwealth Electric Company. The estimated cost of the work is $150,000. The new building will be of brick, stone and steel, and two new 1,000-kw. motor-generator sets will be installed at present, room being provided for six sets. The new apparatus being installed will change the frequency from 25 to 60 cycles.

LOCKPORT.—Bids will be received until Oct. 11 by the Board of Trustees, Sanitary District, Chicago (S. D. Griffin, Clerk) for furnishing electrical apparatus and materials and for installing same in the power house of the Sanitary District of Chicago, near Lockport, and transmission line along the right of way of said District of Chicago. Bids may be submitted as a whole or separately on the following: Main switchboard and instruments; transfer boards, oil circuit-breaker switches and knife switches; remote controlled rheostats for generators; bus bars and bus bar and circuit compartments; conduits, service wiring, transformer and generator connections; transformers and lightning arresters; transmission line towers or poles; erecting towers or poles; copper and aluminum conductors; erection of cable; high tension insulators; electric traveling crane. Cost reported to be $160,000.

INDIANA.

FRANKLIN.—The Franklin Water, Light & Power Company's building has been destroyed by fire.

DANA.—The citizens at a special election voted to install a modern electric light plant in that place.

MATHEWS.—Charles Sampson has been granted a franchise to install an electric light plant in Mathews.

NORTH MANCHESTER.—Dr. D. Ginther and others are reported interested in the construction of an electric light plant at this place.

VALPARAISO.—The Valparaiso Light & Fuel Company has sold its gas and electric light plant to Charles H. Geist, of Chicago, for $60,000.

FRANKFORT.—It is proposed to add a 120-kw., alternating-current generator to the city electric light plant. J. T. Small is superintendent.

NEWPORT.—The Town Trustees are reported to have granted E. E. Sayler, of Saybrook, Ill., a franchise to install an electric light plant at Newport.

WORTHINGTON.—The Indiana Water & Light Company contemplates installing a new arc light system, the adoption of meters and the extension of lines.

NORTH VERNON.—It is proposed to install at the city electric light plant before the fall, an additional 150-kw. unit and boiler. A. B. Berkshire is superintendent.

INDIANAPOLIS.—Officials of the several roads centering at this city have decided on building a power, heat and lighting plant southeast of the Union Station train sheds, to cost $50,000.

MUNCIE.—Among the improvements contemplated by this city is the rewiring of the city electric lighting system and the purchase of 100-ft. stacks. Harry L. McCullough is superintendent.

NOBLESVILLE.—The S. M. Smith Company, owner of the electric light plant, proposes to change from the open arc to enclosed direct-current, 6.6 ampere lamps and rebuild the pole lines. O. N. Eiler is manager.

COLUMBUS.—The Columbus Street Railway & Light Company contemplates constructing a power house, making extensions to the street railway and electric light systems and the addition of a heating plant. R. F. Gottschalk is president.

GREENFIELD.—The City Council has decided to repair the electric l[illegible] plant. The proposition to take individuals [illegible] partnership with the city was not received favorably. Neither was it thought to be advisable to combine the electric and water plants.

JASONVILLE.—The Jasonville Electric Company has been incorporated with a capital stock of $9,000 by David W. Wetnight, H. L. Hyatt and H. L. Hannah, who are directors. The company will receive bids for the construction of an electric light plant.

BRAZIL.—The Brazil Electric Company's new power house on West Main Street, which was recently put in operation, is a model and up-to-date plant. The machinery now installed consists of a 250-kw. Westinghouse generator driven by a four-valve Fleming engine. The two other generators located at the power house at the brewery which have been furnishing current since the company began business, will be moved at once to the new power house and put in position on the foundations which have already been completed for them. The company will then be equipped with the latest approved machinery and will be in a position to furnish excellent service.

PORTLAND.—The City Council of this city has reduced the rate for electric light current to a point lower than that of any other paying plant in Indiana. The light committee and Superintendent Baily reported that it had been found possible to grant a reduction. The new scale is: For 10 kilowatts, 8 cents per kilowatt; 30 kilowatts, 7 cents, and 60 kilowatts or more, 6 cents. The minimum charge is reduced from 75 to 60 cents, the city furnishing the meter. The old rate ran from 9 cents to 7 cents and each rate was stationary to such an extent as to make the reduction equal to 30 per cent. The committee says a sufficient profit is left to pay all expenses of the electric light department, including salaries, and give the city its seventy street arc lights free. When the city plant was under private ownership these seventy arc lights cost $80 each per year.

INDIANAPOLIS.—According to recent statistics gathered by the State Statistician for the year ending June 30, 1905, 32 cities of the 84 in Indiana owned their electric light plants, and 52 cities were lighted by contract with private corporations or parties. The entire cost of lighting for all the cities was $890,666.44. The cost of the 32 cities with municipal plants was $320,327.61, and for the 52 cities lighted by private contract $570,388.83. The receipts from this source in the 32 cities maintaining municipal plants was $345,961.46, leaving an overplus of $23,633.85 for these cities. The average cost per city of those owning plants was $10,010.23, and of those renting the lights was 10,960.15. The average cost of the latter was $955.92 per city greater than the former. Although the number of lights of each are not given, and for this reason no true basis can be had, yet the advocates of municipal ownership are claiming a victory over private management as to cost to the consumer. The total receipts of all the cities of the State maintaining electric light plants during 1905 was $10,022,550.48.

INDIAN TERRITORY.

BARTLESVILLE.—The Bartlesville Electric Light & Power Company has been incorporated.

COWETA.—The Coweta Rolling Mill, Light & Power Company has been organized with a capital stock of $15,000.

CLAREMORE.—The Claremore Light & Power Company has been incorporated, with a capital of $25,000. Incorporators: J. M. Bayless, F. A. Neilson, W. W. Bryan and others.

CHICKASHA.—The Chickasha Light & Power Company (C. E. Ross, Mgr.) proposes installing a 250-h.p. Corliss engine, a 150-h.p. boiler, brick building, and repairs and additions to its lines.

IOWA.

ELDORA.—The Eldora Electric Light Company will make extensive improvements to its plant.

SUMNER.—L. L. Stewart is stated to have secured a franchise for an electric light and power plant.

DENISON.—The Denison Electric Light & Power Company contemplates installing a 50 or 60-kw. unit and a boiler.

PANORA.—The electric light company has under consideration the construction of an electric light plant on the river at Rees' Mill.

BEDFORD.—The Bedford Light, Heat & Power Company proposes to install two new 60-cycle alternating-current generators, one of 40-kw. and the other 100-kw. capacity. M. L. Burt is president.

MADRID.—The Madrid Electric Light & Power Company wants estimates on installing storage batteries of sufficient capacity to carry lights after 12 o'clock and also carry a day current. W. Zenar is chief engineer.

ALBIA.—The Albia Electric Light & Power Company has just started a day circuit, and is in the market for small direct-current motors of ½ to 25 horse-power, 110 and 220 volts. A. R. Jackson is the purchasing agent.

OXFORD MILLS.—The Zinn Electric Light & Power Company is being incorporated by H. A. Zinn, F. E. Zinn and A. L. Zinn, with a capital of $35,000. The company purposes buying the water power and rights, also the mill property of J. R. Zinn & Son at this place.

KEOKUK.—The Keokuk & Hamilton Water Power Company proposes to develop electric power at the foot of Des Moines Rapids and transmit it to cities in the states of Iowa, Illinois and Missouri. It is proposed to develop a minimum of 60,000 horse-power. The estimated cost of the proposed work is $6,000,000. John N. Irwin, of Keokuk, is president; R. R. Wallace, of Hamilton, Ill., is secretary, and Lyman E. Cooley, of Chicago, Ill., is consulting engineer.

ANAMOSA.—The Anamosa Electric Light & Power Company is being incorporated by H. A. and F. E. Zinn, of Oxford Mills, this state, and Park Chamberlain, of this city, with a capital of $35,000. The company will take over the plant, water power and mill property of the Metcalf Light & Power Company and will overhaul the plant and add new boilers, generators and transformers.

KANSAS.

OTTAWA.—F. A. Sharpe, of Lawrence, has petitioned for a franchise for an electric light plant.

HAYS CITY.—The Hays City Electric Light & Power Company proposes to install a 65-kw., 1,100-volt alternator.

ALMA.—A company has been organized by local men at Alma; they are installing a small light plant, alternating system.

GARDEN CITY.—The Garden City Electric Company will soon add to its equipment a 75-kw. dynamo and a 100-h.p. Corliss engine.

LINCOLN.—A committee has been appointed, including A. Marshall, J. Albert Smith and others, to investigate and report on the question of constructing water works and an electric light plant.

WICHITA.—The Wichita Railroad & Light Company is stated to have secured the contract for furnishing 271 arc lights for five years at an annual cost of $14,454. Each light will be run with a power of 460 watts and be lighted at dusk and burn until 1 o'clock. The company will furnish additional lights at $66 per light per year.

KENTUCKY.

LEWISPORT.—Jesse Emmick is interested in the construction of an electric light plant.

PIKEVILLE.—The Pikeville Electric Light Company will install a 100-kw., 250-volt, direct-connected generator.

SOMERSET.—Bids will be received by T. R. Griffin, Mayor, and the Board of Council, for a twenty-year electric light franchise.

RUSSELL.—E. E. Fullerton, of Greenup, writes that bids will be received for the construction of an electric light plant at Russell; probable cost, $5,000.

NEWPORT.—The question of issuing $50,000 of bonds for the purpose of erecting a municipal electric light plant will be submitted to a vote of the people of Newport at the next election. It requires a two-thirds vote to carry.

MIDDLESBOROUGH.—The Middlesborough Electric Light, Heat & Power Company may move its plant to the water works; if not, it is proposed to install a dynamo at the present station and a motor at the water works station. The company would like information about cost of iron poles and undergrund conduits. Address W. M. Todd, manager.

STOUGHTON.—Bids will be received by the Electric Light Committee for a 100-kw. belted three-phase alternator; 100-kw. steam turbo-alternator; two switchboards with instruments; 75-light constant-current transformer; 50 series alternating-current enclosed-arc lamps; water-wheel governor for two 100-h.p. wheels; a 150-h.p. boiler and a boiler feed pump and heater.

LOUISIANA.

WILSON.—The question of constructing water works and an electric light plant is under consideration here.

MARKSVILLE.—Sealed bids for the construction of a system of water works and electric light for the town of Marksville have been received.

ALGIERS.—The Orleans Levee Board has granted permission to the New Orleans Railways Company (A. L. Black, Electrical Engr., 317 Baronne St., New Orleans) to lay a number of cables across the river for the purpose of furnishing the necessary lights and electric wires to Algiers.

ARCADIA.—A company has been organized here with a capital of $5,000 with J. L. Dalton as president and M. L. Tooke as secretary and treasurer. The company has bought the Dalton-Lord electric light plant located here, and it is reported will make considerable improvements and additions.

MAINE.

WATERVILLE.—The Messalonskee Electric Company is reported to have in contemplation the development of another water power. W. Wyman, Mgr., Waterville.

OAKLAND.—The Messalonskee Electric Company, whose incorporation was recently noted, proposes to construct an electric light plant at Oakland to cost $125,000. L. Metcalf, 14 Beacon St., Boston, Mass., is the engineer.

FORT FAIRFIELD.—B. D. Whitney, of Fort Fairfield, engineer of the Maine & New Brunswick Power Company, writes that survey is now being made for the proposed power plant of this company on Aroostook River. A. R. Gould, of Presque Isle, Me., is one of the parties interested.

AUGUSTA.—The Southern Power & Improvement Company has been organized at Augusta, for the purpose of manufacturing, generating, buying and selling electric energy for lighting, heating and power, etc., with $10,000 capital stock, of which nothing is paid in. President, I. E. Fairbanks, of Augusta.

LEWISTON.—The Alfred Light & Power Company, which is controlled by the Atlantic Shore line, has taken over the Linscott and Ester water privileges, which were purchased by Bodwell Brothers some time ago. In developing these privileges they will make one privilege at the Ester dam and that will give them a water power capable of developing 800 horse-power.

OLDTOWN.—The Milford Construction Company has closed a contract with Jas. B. Mullen, of Bangor, Me., to construct a dam and powerhouse. The plant consists of a concrete dam about 1,000 feet long across Penobscot River at Oldtown giving about 25 feet head and a powerhouse containing twelve 1,000-h.p. generators, direct-connected to water wheels. The power produced by the new plant will be transmitted to Bangor, fifteen miles away.

MARYLAND.

LONACONING.—The Lonaconing Electric Light & Power Company expects to install a 90-kw. dynamo. Wm. Atkinson is manager and purchasing agent.

ANNAPOLIS.—Andrew Westervelt, Secretary Maryland Heat, Power & Light Company, writes that about $40,000 will be expended in improvements. Howard E. Crook, president.

BALTIMORE.—The United Electric Light & Power Company is reported to have awarded contracts for the equipment of its power station at Westport as follows: Ten boilers of 700 h.p. each to the Babcock & Wilcox Boiler Company, of New York, four engines of 3,000 h.p. each, and overload capacity of 4,500 h.p., to the McIntosh & Seymour Company, of Auburn, N. Y., and four generators of 2,000-kw. capacity each and overload capacity of 50 per cent, to the General Electric Company, of Schenectady, N. Y. The building, contract for which will soon be let, will be one story, 255 x 110 feet. Between the water front and the building will be extensive coal-storage yards, in addition to the bunker storage provided in the building. A gantry crane 275 feet long will span the distance between the building and the water front to pick up and carry coal.

MASSACHUSETTS.

HOLYOKE.—About $9,500 will be spent on improvements for the municipal electric light plant.

GLOUCESTER.—The Gloucester Electric Company proposes to add to its equipment a 500-kw. Curtis steam turbine.

QUINCY.—The Quincy Electric Light Company may issue $50,000 stock at par, $100, to pay for additions to plant made prior to July 1.

BRIDGEWATER.—The property of the Bridgewater Electric Light Company has changed hands recently, the new owner being Lawrence Cleare of this town.

PLYMOUTH.—At the annual meeting of the Plymouth Electric Light Company the following officers were elected: James N. McCoy, president; Frank C. Calley, treasurer; George H. Adams, clerk; James N. McCoy, Fred P. Weeks, Warren G. Chase, George H. Adams and Frank C. Calley, directors.

HUNTINGTON.—The gas and electric light commissioners have issued an order approving the issue of $5,000 of new capital stock by the Huntington Electric Company for the purpose of purchasing the electric lighting plant and business in Huntington formerly owned and operated by ex-Representative Henry E. Stanton.

FALL RIVER.—The Fall River Electric Light Company is to issue $250,000 capital stock, to be offered to stockholders at $130 a share. The proceeds of 190 shares must be used for the cancellation of a like amount of floating debt on account of the purchase of land, and proceeds of the remaining 2,310 shares are to be used in payment of additions made subsequent to May 1.

NEW BOSTON.—Engineer H. F. Keith, of Mt. Washington, Mass., with a corps of engineers, is reported to have arrived at New Boston, to make surveys and ascertain the cost of an electric power plant, a charter for which is reported to have been granted by the recent Connecticut Legislature. The company proposes to sell and transmit electric power to various cities in Massachusetts and Connecticut.

LEOMINSTER.—The Heat, Light & Power Corporation of Boston has made a deal for the purchase of the Leominster Electric Light & Power Company. The ratification of the deal and the transfer of stock will follow the annual meeting of the trustees of the Leominster company. The price agreed upon is about par for the capital stock of the Leominster company, which is $50,000. The Heat, Light & Power Corporation already operates several plants in Worcester county, besides others elsewhere.

CAMBRIDGE.—The Cambridge Electric Light Company has completed arrangements for a reduction in its tariff to customers to take effect from and after October 1, 1905. The basic rate for incandescent house lighting will be changed from 16 2-3 cents to 15 cents per kilowatt hour. The old rate of 16 2-3 cents allowed a reduction of 15 per cent. for prompt payment, making the rate 14.17 cents net. The new rate allows a reduction of 10 per cent., making the net price 13½ cents, a saving of .67 cent. In addition the company will supply free renewals of lamps, so that the total reduction to customers will be about 10 per cent. The reduced rates will also apply to small stores and offices.

MICHIGAN.

ADRIAN.—The Citizens' Light & Power Company contemplates installing a 500-h.p. turbine and boiler outfit.

ALPENA.—Richard Collins has been awarded the contract for the power house of the new water works, at $16,055.

L'ANSE.—The Superior Construction Company, of Houghton, is reported to be preparing plans for a municipal lighting plant for L'Anse.

ROSE CITY.—Frank G. Bell and James Monaghan have made application to the City Council for a franchise for an electric light plant.

SAGINAW.—The Bartlett Illuminating Company is stated to have secured the contract for lighting the city for five years, at $60 per light per year.

MARSHALL.—P. A. Mumaw, Village Recorder, writes that probably nothing will be done this year toward improving the water works and electric light plant.

MASON.—A new boiler, engine, alternating-current dynamo, switchboard, etc., are needed for the municipal electric light plant. R. E. Darling is superintendent.

GRAND RAPIDS.—The city authorities have been requested to open negotiations for the lease of the municipal electric lighting plant to a syndicate of eastern capitalists.

HASTINGS.—The Hastings Gas Company has sold its plant to the Thornapple Electric Company, which will hereafter be known as Thornapple Gas & Electric Company.

ESCANABA.—The Board of Public Works is reported to have petitioned Council for an appropriation of $14,000 to purchase additional machinery for the electric light plant.

PONTIAC.—The Pontiac council has not yet settled the street lighting proposition. The Pontiac Standard Lighting Company, the Pontiac Light Company and the Clinton River Power Company are bidders for the contract.

KINGSLEY.—The village has let the contract for furnishing electric lights to A. Gibbs, of Mayfield, Mich. The contract calls for five arc lights and more to be furnished as needed. Mr. Gibbs will also furnish commercial lighting.

KALAMAZOO.—The old factory buildings of the Kalamazoo Electric Company have been purchased by the Kievet & Lounsberry Company, manufacturer of engines and boilers. The plant will be remodeled and put in shape for the new company in a short time.

HOUGHTON—The Houghton County Electric Light Company has elected the following directors: Henry G. Bradlee, James R. Dee, Waldo E. Forbes, Henry R. Hayes, William L. Putnam, Russell Robb, Charles A. Stone, Edwin S. Webster and Charles D. Wyman.

HART.—The Pere Marquette Power Light Company, it is stated, has been granted a 10-year franchise by the Council to furnish current to the village. The company will dam Ruby Creek, build a turbine plant and furnish light and power to Pentwater, Hart and Shelby.

BIG RAPIDS.—The Michigan Heater Company, which is rebuilding the burnt portion of its plant for the Hanchett Sewage Works, is also figuring on generating electric power to supply its own needs, the needs of the Hanchett Sewage Works and also to give the city a day current.

DETROIT.—The Public Lighting Commission of Detroit has let the contract for a new turbine engine, with a capacity for 4,000 arc lamps, to the Westinghouse Machine Company of East Pittsburg, Pa. Of the bids put in for this unit several weeks ago, the Westinghouse was the lowest at $61,283.

STANDISH.—The Rifle River Power Company has petitioned the Board of Supervisors of Arenac County, at Standish, for permission to construct three dams across Rifle River, the power developed to be used for electrical purposes. Geo. D. Silsby, President; Frank F. Kleinfield, Secretary, and H. E. Terry, Engineer, all of Saginaw.

PONTIAC.—The Pontiac Savings Bank and the Citizens' Savings Bank, of Holly, have taken possession of the Holly Milling Company at Holly. This also includes the Holly Electric Light & Power Company. C. H. S. Poole, president and majority stockholder of the company, it is said, is indebted to the banks in the sum of $15,000.

JACKSON.—The Commonwealth Electric Company has commenced the erection of a big dam in the Kalamazoo River, near Ceresco, five miles west of this city. It is the purpose of the company to furnish more direct power for the Jackson & Battle Creek Traction Company, and it is thought that 1,000 horse-power can be obtained from the dam.

CASS CITY.—Surveys are now being made for the construction of a dam for the municipal electric light plant, about four miles southwest of Cass City, on Cass River. If the report is satisfactory the water power plant will be built next spring, for which a new equipment of dynamos, motors and pumps will be needed. Wm. N. Strube is superintendent and chief engineer.

MONROE.—The City Council recently passed a resolution for the sale of the municipal lighting plant to the General Construction Company, Ltd., for $25,000, including a 10-year contract and franchise, lights at $56 per year. Both the sale and contract will have to be ratified by the people at a special election. Geo. T. Wolf, of Three Rivers, is one of the stockholders of the company.

BENTON HARBOR.—The power at the Buchanan village dam, which is controlled by Charles A. Chapin, is to be transferred in part to Benton Harbor and St. Joseph. Another dam will be constructed at King's landing, where Chapin has a large site. A recent decision of the Supreme Court gave Chapin the right to sell the power where he desired, despite the exclusive contract with Buchanan.

ANN ARBOR.—The Washtenaw Light & Pow-

er Company, of this city is to be united with the light and power system of Detroit, and within a few months a feed wire will be run from the Geddes plant to the county line to connect with a feed wire from Delray. The companies concerned are all controlled by the North America syndicate, which is preparing to develop extensively the power of the Huron River.

MUSKEGON.—The Shaw Electric Crane Company is planning to drive all of the machinery of its great shops at Muskegon Heights by electric current, to be furnished by the Grand Rapids-Muskegon Water Power Electric Company. The machinery is now driven electrically from the Shaw Company's own plant. A new 400-h.p. rotary converter will be put in by the Shaw Company.

DETROIT.—C. Hayward Murphy, of the Murphy Power Company, writes that it is proposed to construct a power house for the generation of electricity and steam; also a cold-storage warehouse. J. F. Lewis is Superintendent and Engineer.

The Public Lighting Commission (H. P. Hetherton, President) will within one year install one 2,000-kw. unit.

CLARE.—The village has renewed its contract with the Clare Electric Company for lighting the streets for five years at $4.90 per month for each light. Senator Doherty desired a contract to the end of his franchise nine years hence and offered light for $4.75 a month if the longer contract was granted. The city expects to be in shape to take over the lighting plant at the end of the five-year contract. The rate established will make the cost of lighting the streets $800 a year.

GRAND RAPIDS.—The Cascade Electric Company, which has acquired flowage rights on the Thornapple River, is seeking a franchise in the city to furnish commercial lighting and power. The proposed franchise prohibits the company from charging more than 15 cents per kilowatt-hour for lighting and 4 cents per horse-power-hour for power, and forbids the company disposing of the franchise to a competitor. The management of the enterprise is vested in Frederick C. Miller, and associated with him are Ernest A. Stowe, Stephen Sears, Robert W. Irwin, A. Hompe, C. C. Follmer, Henry Idema, Walter C. Winchester and Guy W. Rouse, all Grand Rapids men.

MINNESOTA.

PINE CITY.—The Pine City Milling & Electric Company has contracted for a new dynamo of 750-light capacity.

STARBUCK.—Mr. A. H. Dreyer, superintendent of the village lighting system, reports the addition of a new 30-kw. dynamo and a 50-h.p. engine.

MARSHALL.—It is proposed during the coming year to remodel the entire equipment of the municipal electrical light plant. E. Simmons is superintendent.

BROWNS VALLEY.—E. R. Marshall, City Recorder, writes that a committee has been appointed to investigate the question of constructing an electric light plant.

RUSHFORD.—The Rushford Power Company has been granted a 30-year franchise for an electric light system here. The secretary writes that the proposed work contemplated by this company will cost about $18,000. D. J. Tew, C. H. Grier, J. Webster and others are among the parties interested.

MISSISSIPPI.

HOUSTON.—Bids will be received until Sept. 1 by J. M. Griffin for $13,500 water and light bonds.

PONTOTOC.—The citizens are reported to have voted to issue bonds for the construction of an electric light plant.

SARDIS.—The Panola Electric Light & Power Company expects to put in a series arc light circuit for street lighting about January 1 next.

GRENADA. —The improvements contemplated at the municipal electric light and water plant are reported to include the purchase of two new generators. B. C. Adams, Mayor.

PHILADELPHIA.—The Philadelphia Compress, Electric Light & Ice Manufacturing Company has been incorporated with a capital stock of $30,000 by A. M. Boyd and others.

GLOSTER.—This city is reported to have in contemplation the installing of duplicate dynamos and engine within twelve months at the city electric light plant. Howard E. Pigford, Mgr.

HAZLEHURST.—The citizens are reported to have voted to issue $10,000 bonds, to be used for enlarging the school grounds, adding more water mains, and increasing the lighting facilities.

UNION.—The Gulf States Investment Company has been incorporated with $200,000 capital stock, by S. M. Jones, F. L. Riley and R. W. Jones, to operate lighting plants, water works, sewerage systems, etc.

MISSOURI.

SKIDMORE.—The question of lighting this place by electricity is reported under consideration.

CAPE GIRARDEAU.—The Cape Girardeau Water Works & Electric Light Company (Thos. Fox, Supt.) will construct new gas plant this fall.

KANSAS CITY.—The Kansas City Electric Light Company (R. E. Richardson, Mgr.), it is reported, will put in new conduits.

JOPLIN.—The Spring River Power Company proposes to construct a new power plant. The Arnold Company, of Chicago, Ill., is the engineer.

COLUMBIA.—John S. Bicknell, City Clerk, writes that it was voted August 8 to issue $10,000 water and electric light bonds and $10,000 public sewer bonds.

ST. LOUIS.—The Board of Public Improvements is considering bids for furnishing electricity at the city institutions for one year from September 1. During the present year the expense has been $22,000. The contract includes power for all of the fire engine houses and other city buildings.

CARONDELET.—Henry C. Scott, president of the Edison Electric Company of Carondelet, St. Louis, has entered a protest with the Board of Public Improvement of St. Louis, alleging that the Union Electric Light & Power Company has violated its agreement with the city of St. Louis by refusing to allow the Carondelet company to string wires on the Union poles in South and West St. Louis. No room on the poles is given as the basis for refusal, but Mr. Scott offers to buy the poles and rent them to the Union company at the price stipulated by the city.

MONTANA.

LIVINGSTON.—Ground has been broken for the new power plant which the Livingston Water-power Company will erect on the Yellowstone River. The company expects to expend about $200,000.

BUTTE.—Samuel T. Hauser, of Helena, former Governor of Montana, is interested in the construction of a second dam across the Missouri River. It is proposed to transmit the power to Anaconda.

NEBRASKA.

NELSON.—The Nelson Electric Light Company has its power house enclosed, and will soon begin installing the machinery.

FALLS CITY.—This city has voted an issue of $36,000 bonds for public improvements, of which $10,000 are to be used for constructing an electric light plant.

YORK.—The York Electric Light & Power Company and the York Gas Company have effected a consolidation and will be known as the York Electric Light, Gas & Power Company. C. A. Haas of Omaha has been elected president and J. A. Peffer manager.

NEVADA.

WINNEMUCCA.—It is reported that the electric light plant has been damaged by fire.

RENO.—A deal for the consolidation of Reno's two electric companies has been pending for some time, but H. C. Cutting, its promoter, has left the city, and it is believed that the project is now off.

NEW HAMPSHIRE.

CONCORD.—The Concord Electric Company has closed its plant at Sewall's Falls for repairs and improvements, and is supplying electricity from its steam plant on Bridge St. and from Garvin's Falls.

NEW JERSEY.

NUTLEY.—The Town Council has granted a four-year contract to the Public Service Corporation for the lighting of the streets of the town at $16 per lamp.

WOODSTOWN.—The Woodstown Ice & Cold Storage Company, which lights this town, proposes to install a larger dynamo and engine. C. F. Moore is manager.

NEWARK.—Wm. J. Lansley, of Englishtown, engineer for the Manalapan Light Company, writes that the cost of the proposed work contemplated by this company is $40,000. The General Electric Company furnishes the generators.

ATLANTIC HIGHLANDS.—At the municipal electric light plant, it is expected to change over to alternating enclosed arcs and the alternating system to 2,000 primary and 60 cycles. A new dynamo and engine will also be installed. F. E. Price is superintendent.

KEARNY.—The Kearny Common Council has discovered that it has no power to issue bonds for a municipal plant, and has instructed its Lighting Committee to make a contract with the Public Service Corporation to light the streets for one year only at the reduced price offered by the company—$97 a year for arc lights and $15 a year for incandescent lights. The reduced offer made by the corporation was for a term of five years, and it is probable that the company will refuse to renew the contract, which expired on August 1, for a year at the reduced prices, and will compel the town to pay $100 a year for arc lights and $16 for incandescents.

NEW MEXICO.

RATON.—The Raton Electric Light & Power Company will install a new boiler, engine and a 150-kw. alternating-current dynamo.

CARLSBAD.—A large power dam has been finished to replace the one destroyed by the storm last fall, and this town is again lighted by electricity.

ROSWELL.—The Roswell Electric Light Company has in contemplation the purchase of an entire new equipment for its power house. J. H. Cook is superintendent.

LAS VEGAS.—The City Council has granted a 50-year franchise for street railways and electric lights to Wm. A. Buddecke, of St. Louis, Mo., owner of the present electric railway system. Extensions to the system to cost $15,000 have already begun.

SILVER CITY.—The City Council has granted a 50-year franchise to Geo. T. Schmelzel and associates for electric lighting purposes in this city. The franchise requires that work be commenced on the installation of the plant within ninety days and that the plant be in operation within six months.

NEW YORK.

LOWVILLE.—The Wetmore Electric Company proposes to install a 500-kw. alternator and a pair of water wheels. L. Wetmore is manager.

CHATHAM.—The electric light plant at Chatham has been sold to the Lindewald Light & Power Company, which is composed of Chatham capitalists.

SALAMANCA.—This village proposes to take over the present water and lighting plants on January 1, 1906, if it is voted to do so at the special election, to be held soon.

LESTERSHIRE.—The Village Board of Trustees has contracted with the Light, Heat & Power Company of Binghamton for five years for the lighting of 30 lights and the main street.

PENN YAN.—The Yates Electric Light & Power Company proposes to rebuild and install two 400-h.p. Victor turbines of the horizontal type, direct-connected to two 150-kw. generators.

NORTH TONAWANDA.—The Tonawanda Power Company, of North Tonawanda, has secured the contract for lighting the city (bids

opened July 1) at $75 per arc light per year for a term of two years.

BUFFALO.—It is reported that the control of the Niagara, Lockport & Ontario Power Company has passed into the hands of a new syndicate of capitalists headed by John J. Albright, of Buffalo, and Mr. Westinghouse, of the Westinghouse Company, and it is stated that extensions are to be made.

LOCKPORT.—The citizens of Lockport are considering a proposition just made by the Albright, Green and Hayes interests of Buffalo, representing the Ontario Power Company, to furnish to the residents of Lockport electric power at $16 per horse-power. They purpose to furnish power in blocks of 100 horsepower at the transmission station on the Ernest farm. The offer is receiving favorable consideration from the business interests of the city.

NORTH CAROLINA.

FAYETTEVILLE. — Electric light bonds amounting to $30,000 have been sold.

ROCKINGHAM.—It is proposed to install a new dynamo at the municipal electric light plant.

SOUTHPORT.—The town of Southport is considering the question of a municipal electric light plant. Several bids for the plant have been received.

RALEIGH.—The Raleigh Electric Company proposes to construct two miles of railway and extend the lighting system. W. J. Andrews is president and manager.

ASHEVILLE.—The Asheville Cotton Mills will soon be operated by electric power from the Weaver power plant on the French Broad River, five miles from Asheville, N. C.

MORGANTON.—W. A. Mauney, of Kings Mountain, and J. M. Torrence, of Morganton, will organize a company to construct an electric light plant and erect a cotton factory.

WINSTON-SALEM.—The Winston-Salem Power Company, with $125,000 capital, has been chartered in North Carolina, and will develop electrical properties, etc. F. H. Fries and others are the incorporators.

GREENSBORO.—The State has authorized the Greensboro Electric Company to increase its capital stock from $250,000 to $500,000, the additional issue being of preferred stock. John Kerr is the president of the company.

CHARLOTTE.—The development of the Catawba River by the Southern Power Company, of Carlotte, will, it is predicted, result in the establishment of many new small industries at points reached by the lines of the new $7,500,000 concern. A total of 75,000 horse-power will be developed.

OHIO.

STRASBURG.—Contracts are being let by the Strasburg Electric Company for doubling the capacity of the plant.

URBANA.—Architect Wm. Miller, of Springfield, is preparing plans for the $5,000 electric lighting plant to be erected here .

HUBBARD.—The incorporated village of Hubbard has issued bonds to the amount of $2660 to be used for additional electrical equipment.

MOUNT VERNON.—Mr. Carl Hoster and Samuel Blumenthal, of the Hoster Brewing Company, intend to install a large electric plant.

TOLEDO.—Frank I. Consaul, chief engineer of the Board of Public Service, estimates the cost of constructing a municipal electric light plant at $470,400.

BELLEFONTAINE.—Seventeen bids were received for the $50,000 electric light improvement bonds at Bellefontaine a few days ago. The highest was $53,672.

ADA.—The Ada Water, Heat & Light Company will require about ten miles of construction material for its extension to Algiers. B. S. Young is secretary and manager.

TOLEDO.—It is reported that the question of holding an election to vote on the issuing of $500,000 bonds for a city lighting plant is under consideration by the City Council.

OBERLIN.—The Oberlin Gas & Electric Light Company, of Oberlin, has been incorporated with a capital of $10,000, by W. B. Whiting, C. F. Brooks, A. J. Sperry and others.

CAREY.—At the village electric light plant it is proposed to add a 75-kw. alternating-current generator and a separate engine for the arc lighting. Harry C. Fink is manager.

GALION.—The Crawford County Gas & Electric Company intends constructing a new power house at a cost of $40,000. S. N. Blake, 15 Westminster St., Providence, R. I., is the president of the company.

PLYMOUTH.—All bids received August 9 for furnishing material and equipment for an electric light and water plant have been rejected and new bids were called for August 28. John T. Bulman is Clerk of the Board of Public Affairs.

READING.—Engineer Geo. Hornung, of Cincinnati, has been engaged to design an entire new plant for Reading to take the place of the present electric light plant. New boilers, engines, generators, street lamps and line work will be required.

COLUMBUS.—The Board of Public Service of Columbus has signed a contract permitting the Columbus Railway & Light Company and the Public Service Company to use the city poles for their lines at 15 cents a contract. The companies were refused the use of the poles some months ago.

ARCANUM.—The following are reported to be the bids opened by the Board of Public Affairs for the construction of water works and an electric light plant: Ryan Construction Company, Indianapolis, Ind., $37,000; Baker, Niswonger & Warner, Arcanum, $34,914; P. H. Porter, Clinton, Ky., $34,816; and the Olds Construction Company, Fort Wayne, Ind., $34,743.

OREGON.

TIPTON.—W. A. McNaughton, of Tipton, it is stated, is arranging for the construction of an electric power plant on Strawberry Creek.

OREGON CITY.—The Portland General Electric Company is reported to be arranging to construct an electric plant on the east side of Willamette River in Oregon City, just below the falls. E. Hippeley, of Portland, is chief engineer.

BAKER CITY.—It is reported that a corps of engineers has been engaged by the Baker Light & Power Company to make surveys from power site on Rock Creek over the ridge into Bourne, and along Cracker Creek to the various mines using power.

PORTLAND.—Jas. Barrett, it is stated, has secured the contract to build a stone power house 50 x 50 and 30 ft. high at the golf links for the Oregon Water Power Company. It is also stated that he has secured the contract to construct a dam and canal or tail race at Cazadero that will require 7000 cubic yards of stone. Both contracts are in connection with the power plant which is being constructed on Clackamas River.

SPRINGFIELD.—An Eastern syndicate which owns electric plants in Spokane, Walla Walla, Salem and other cities, has purchased, according to reports, through its agent, A. Welch, of Salem, the plant of the Lane County Electric Company, at Springfield, which furnishes light for that town and Eugene. The syndicate will take control of the plant in October. It is stated to be the intention of the company to increase the plant to 1000 horse-power, and also that the construction of a system of electric railways in Willamette Valley is contemplated.

PENNSYLVANIA.

WEATHERLY.—The Town Council has decided to construct a new electric light plant.

LOCK HAVEN.—The Electric Light Company has in contemplation the enlargement of its plant on E. Church Street.

COLUMBIA.—The Lancaster County Electric Light & Power Company has decided to construct a power station at Columbia.

KUTZTOWN.—This borough has decided to issue bonds to the amount of about $8000 for the construction of an electric light plant.

HUGHESVILLE.—The Citizens' Electric Light & Power Company is preparing plans for a power plant. John B. Fox is secretary.

WOMELSDORF.—Wm. H. Dechant, of 536 Penn Street, Reading, is preparing plans for the construction of an electric light plant at Womelsdorf.

HYNDMAN. — The Hyndman Electric Light, Heat & Power Company expects to install a larger engine in the near future. N. A. Blair is president.

MAHANOY CITY.—The Mahanoy City Light, Heat & Power Company (Wallace Haldeman, manager) will shortly install a 300-h.p. water-tube boiler.

SOMERSET.—The Somerset Electric Light, Heat & Power Company will add a 300-kw. alternator and a 600-h.p. engine. J. M. Bricker is manager.

SHAMOKIN.—The Shamokin Light, Heat & Power Company expects to replace its present machinery with 600-kw., 60-cycle, 2200-volt, two-phase generators.

LEWISBURG.—Philadelphia capitalists are reported to have purchased the plant of the Lewisburg Gas & Electric Company, and will make some improvements.

TREMONT.—The Tremont & Pine Grove Electric Light & Power Company proposes to extend its system to Pine Grove, a distance of six miles, and to Donaldson, one mile. Geo. Bernd is superintendent.

WILLIAMSPORT.—The Lycoming Electric Company has decided to lay conduits for underground wires in connection with the building of its proposed new power plant on Hepburn Street. Ernest H. Davis is manager.

MILLERSBURG.—Dreibelbis & Company, of Reading, are completing plans for the construction of a 50,000-h.p. plant about a mile north of Millersburg, along the Susquehanna River. The probable cost of the proposed work is $1,500,000.

PHILADELPHIA.—Articles of incorporation have been filed by the Wyoming Gas & Electric Company, with a capital of $150,000, to manufacture and operate gas and electric plants. The incorporators are John McPeak, Wm. F. Eidell and Frank R. Hansell.

READING.—The Reading Illuminating Company, recently incorporated with a capital of $100,000, is making preparations to construct a power plant and install the necessary equipment in the way of wires, cables, conduits, etc. The directors are Gustav Ulbricht, of Brooklyn, N. Y.; Ralph W. Gifford, of New York, N. Y., and Daniel J. Driscoll, of Reading.

M'CALL FERRY.—A mortgage of $10,000,000 has been filed in the Recorder's office at York to secure a bond issue for the McCall Ferry Power Company, a corporation of New York capitalists, who propose building a power plant on the lower Susquehana River near McCall Ferry. The Knickerbocker Trust Company, of New York City, is reported to be named as the trustee for the bondholders.

PITTSBURG.—H. P. Dilworth, of the Dilworth Coal Company, and Chas. Arbuckle Jamison, of Arbuckle & Company, and Stewart Robinson, a realty dealer, are reported to have secured from the U. S. Secretary of War the right to use water flowing over Springdale dam, in the Allegheny River, for power purposes. It is reported that a $400,000 plant will be constructed and power will be furnished for the traction roads in Allegheny Valley and power and light lines will be extended to Tarentum, New Kensington, Oakmont, Creighton, Natrona and Parnassus.

SOUTH CAROLINA.

SUMTER.—The Sumter Electric Light Company has been incorporated with a capital of $200,000.

HARTSVILLE.—There is reported to be some talk of constructing water works, a sewerage system and electric light plant here.

ANDERSON.—The stockholders of the new Hatton's Ford Power Company, at Anderson, recently met and organized by the election of a board of directors, who then chose officers, with

R. S. Ligon, of Anderson, as president. It is estimated that 6000 horse-power is available at the shoals to be developed. The company is capitalized at $150,000 and will offer power for light and manufacturing purposes.

COLUMBIA.—The Columbia Electric Street Railway Light & Power Company is reported to have taken over the Columbia Water Power Company. Among the improvements contemplated is the relaying of rails on Main Street, the entire ovehauling of the electrical appliances and the thorough equipment of the entire plant. Extensive improvements and additions to the power plant are also contemplated. The new officers include Edwin W. Robertson, president, and W. M. Shannon, electrician.

SOUTH DAKOTA.

BELLE FOURCHE.—The franchise for an electric light plant in Belle Fourche has been let to the Belle Fourche Power & Water Company, which is controlled by A. H. Marble, A. A. Moodle and others.

TENNESSEE.

CLARKSVILLE.—The Queen City Electric Light & Power Company proposes installing a 500-kw. Curtis turbine, a 200-kw., three-phase, alternating-current generator, a 250-kw. motor generator set, new switchboard, three water-tube boilers, etc.

BOLIVAR.—The following are the contracts awarded for furnishing material for the water and light plant: Two 60-h.p. return tubular boilers, Southern Engine & Boiler Works, Jackson, Tenn., $1000, and 100-h.p. engine, at $1247; heater and feed pump, to E. G. T. Colles & Company, Chicago, Ill., $186; electrical apparatus, Electric Supply Company, Memphis, Tenn., $2266, and electrical supplies to Ewing-Merkle Company, St. Louis, Mo., $755. Granbery Jackson, Nashville, Tenn., is the engineer.

KNOXVILLE.—The properties of the Knoxville Traction Company and the Knoxville Electric Light & Power Company of Knoxville, have been consolidated into one company, which will be known in the future as the Knoxville Railway & Light Company. This company has been incorporated with a capital stock of $2,000,000, the incorporators being C. H. Harvey, E. E. McMillan, William S. Shields, F. L. Fisher and Leon Fender. Charles H. Harvey, president and general manager of both companies as they had existed heretofore, says that the charter was taken out for the purpose of consolidation of the two interests to expedite the work of improving the lines and service.

TEXAS.

SAN SABA.—The San Saba Light & Ice Company has increased its capital stock from $15,000 to $30,000.

WHITNEY.—Collier Bros. are reported interested in the construction of an electric light plant at Whitney.

DALLAS.—The Egan Electric Company has been incorporated with a capital stock of $15,000 by G. H. Egan, D. L. Gobble and G. G. Wright.

MASON.—The Mason Electric Light Company is now owned by W. Ellebracht, of Mason. It is proposed to install a 70-h.p. engine to take the place of the two engines now in use.

SAN ANTONIO.—The San Antonio Gas & Electric Company proposes installing a 500-kw. alternating-current generator. It is reported that C. A. Zilker, of Bloomington, Ill., is promoting an organization with a capital of $500,000 to build an electric light plant.

DALLAS.—The Dallas Electric Light & Power Company has obtained sanction for the erection of its proposed electric light and power plant, the permit stating that the building will cost $125,000, exclusive of the machinery. It is understood that the mechanical equipment will cost about $350,000. The building will be 75 x 100 feet, of brick and steel. Construction work has been begun.

LLANO.—John W. Maxcy, designing engineer, of Houston, writes in regard to the construction of a power plant on Llano River, and a system of irrigation, that the probable cost of the proposed work is $85,000, and will include masonry dam 900 feet long and 18 feet high, penstocks, two turbines, draft tubes, electric generator, electric transmission line, 200 horsepower to be developed for lights, water works, etc.

UTAH.

PROVO.—The citizens are reported to have voted to issue $91,000 bonds, to be used for the completion of the water works and the construction of a municipal electric light plant.

SALT LAKE CITY.—The County Commissioners are reported to have granted Emil J. Raddatz a franchise to construct and operate an electric transmission system to Bingham Junction and Sandy.

DESERET.—An ordinance has been passed by the Council, according to reports, granting a 50-year franchise to the Utah Light & Railway Company. R. F. Hayward, electrical engineer, Salt Lake City.

VERMONT.

BARNET.—The Pioneer Electric Company will install new water wheels this fall. A. S. Hunt is manager.

ST. JOHNSBURY.—The St. Johnsbury Electric Company intends making improvements to its plant, but has closed all contracts for the improvements. E. E. Gage, superintendent.

ESSEX JUNCTION.—L. M. Farnham, of Boston, Mass., has, with Mr. Nash, of Burlington, been in consultation with S. A. and C. W. Brownell regarding the development of the water power on the south side of the river for an electrical plant. Plans have been submitted and are under consideration.

VIRGINIA.

STAUNTON.—It is stated that a receiver has been asked for the Augusta Electric Company. The company has failed to pay interest, but claims a contract whereby forfeiture will not lie, and to test this point application has been made for a receiver.

PULASKI.—John F. MacKee, Mayor, writes that bids were received on August 15 for the construction of a building and new machinery for a 150-kw. dynamo. The present plant, 75-kw. dynamo, engine and boiler, will be for sale as soon as new plant is completed.

WINCHESTER.—E. Purcell & Company, of Harrisonburg, are reported to have secured the contract for constructing a dam, power house and raceway along the Shenandoah River, near Millville, for the Winchester & Washington City Electric Railway Company, which is to be used for furnishing power for electricity in Winchester and other towns in this section.

RADFORD.—The Grayson Electrical Corporation, it is stated, will build a power house at Graysontown, eight miles from Radford, to light the towns of Christiansburg, Childress and Riner, furnish power for a contemplated trolley line from Cambria to Christiansburg, besides such factories as may be established along the line. The company has a contract with the town of Christiansburg for the exclusive right to furnish light and power to the town for thirty years. Guy Grayson is president and W. C. Grayson, vice-president.

WASHINGTON.

GRANITE FALLS.—O. Lewis, of Snohomish, is reported to have secured a franchise for an electric light plant.

TACOMA.—The Mountain Home Electric Company has been incorporated with a capital of $30,000 by J. J. Hewitt, of Tacoma, and Seymour H. Bell, of Sumpter, Ore.

BLAINE.—The Blaine General Electric Company, it is reported, has been incorporated with a capital of $50,000 for the purpose of supplying Blaine with light and power. It is to be run by the owners of the Monarch Mill.

PORT TOWNSEND.—A company of local capitalists, who were refused an electric light and gas franchise by the City Council at the last session, are negotiating with the Port Townsend Electric Company for the purchase of its plant and franchise.

PULLMAN.—Improvements are to be made to the city electric light plant. The entire line is to be rebuilt and an electric pumping engine installed for city pumping, and a 75-h.p. motor, direct-connected to a centrifugal pump, 18 additional arc and 50 series incandescent street lamps, 25 to 40 commercial arcs and 1500 commercial incandescent lights are to be installed, and other improvements made. The Washington State College is to be supplied with power. D. F. Staley, Mayor; H. V. Carpenter, Chairman Electric Light Committee.

WISCONSIN.

AUSTIN.—A. S. Campbell is building a power plant near here to supply the city with electricity.

KAUKAUNA.—The Kaukauna Electric Light Company has applied for a lighting franchise in Little Chute, Wis.

BURLINGTON.—At a special election the proposition to vote $12,000 for a municipal electric lighting plant was carried.

JANESVILLE.—The Janesville Electric Company proposes extending its system to Milton and Milton Junction. P. H. Korst is manager.

PRINCETON.—The citizens, it is reported, voted to issue $12,000 bonds to purchase the plant of the Citizens' Electric Light & Power Company.

FLORENCE.—The Pine River Improvement & Power Company is reported incorporated, with a capital of $100,000, by E. W. Hopkins and E. A. Edmunds.

GREENWOOD.—The contract to construct an electric light plant has been awarded to W. D. Lovell, of Minneapolis, Minn., at $14,950. Elias Peterson, City Clerk.

SHAWANO.—The Flattock Water Power Company, of Shawano, has been incorporated, with a capital of $50,000, by H. C. Zachow, Chas. H. Hartley and Frank S. Baker.

FOND DU LAC.—The Independent Light, Heat & Power Company, of Fond du Lac, has been incorporated with capital of $25,000, by Robert Free, G. R. Hoffman and Frank D. Fulton.

PLATTEVILLE.—The Platteville Electric Light & Power Company will this fall add a 50-kw. generator and an 80-h.p. engine, direct connected; beginning early in the year 1906 the company contemplates installing machinery to double the capacity of the plant. J. H. Evans is secretary.

STOUGHTON.—Bids have just been received for electrical apparatus and power equipment, the work to be let as follows: Power house, 150-h.p. water-tube boiler, 150-h.p. steam turbine and generator, 100-kw. generator and 2 exciters, 2 switchboards, arc light transformers, 50 arc lamps, water wheel governor for two 100-h.p. wheels; condenser, feed-water heater and pump, old arc machine and switchboard for sale. John Holton, Chairman of Electric Light Committee.

WYOMING.

LARAMIE.—W. C. Sterne, of Littleton, Colo., secretary of the Arapahoe Electric Company, of Littleton, is reported interested in the construction of an electric light plant at Laramie.

CANADA.

ST. MARYS, ONT.—The citizens are reported to have voted to issue $15,000 bonds for the extension of the electric light plant and water works.

INGERSOLL, ONT.—The Ingersoll Electric Power & Light Company proposes installing new boiler, station equipment, etc. H. Richardson, manager.

BRANTFORD, ONT.—The Brantford Electric & Operating Company, Ltd., proposes installing a 500-h.p. steam plant. Louis W. Pratt, superintendent.

MOOSE JAW, N. W. TER.—Bids will be received by John D. Simpson, secretary-treasurer, for a 200-h.p. boiler, 350-h.p. engine, condenser, feed pump and heater, 225-kw. alternating-current generator, exciter and switchboard.

WESTMOUNT, QUE.—Improvements are to be made here at a cost of $200,000, including the construction of an electric light plant. Ross & Holgate, of Montreal, Que., are the engineers in charge. A. D. Shibley, assistant secretary-treasurer.

American Electrician.

Vol. XVII. New York, October, 1905. No. 10.

MODERN RAILROAD TERMINAL POWER PLANT.

GENERATING STATION OF THE NEW YORK CENTRAL & HUDSON RIVER RAILROAD AT WEEHAWKEN, N. J.

The New York Central & Hudson River Railroad has recently completed at its Weehawken, N. J., terminal a magnificent power plant, the purpose of which is to generate electricity to light the large car storage and classification yards, depots, shops, elevators, docks, and to furnish power to repair shops, transfer bridges, roundhouse, grain elevators, etc. The plant has a total capacity of 2000 rated boiler horse-power, and embodies in its design the latest practice for power and lighting service. Alternating current is used almost exclusively, 600-volt current being used for power and 2300 volts for lighting, the latter being stepped down to lower voltages where desired, and transformed into direct current in a few instances. The electric lighting system comprises both arc and incandescent lamps, enclosed arcs and 110-volt, 32, 16 and 8-c.p. incandescent lamps being used. A huge export grain elevator lately erected on Pier 7 is equipped throughout for motor drive, the total capacity installed aggregating 3300 horse-power, and in order to to provide a minimum risk from fire and explosion these motors are all of the induction alternating-current type.

FIG. 1.—ENGINE ROOM, TERMINAL POWER PLANT OF THE NEW YORK CENTRAL RAILROAD AT WEEHAWKEN, N. J.

The length of the yard at Weehawken is over a mile and a quarter and power is used at widely scattered points, the depot and roundhouse being at one end of the yard, the marine shops at the other end, and the huge grain elevators in the middle. The point of greatest power consumption being at the elevators, the power plant is located almost exactly at the middle of the yard for economical reasons. It was impossible to locate it close to the elevators because of poor foundation facilities, so the power house was erected in a recess at the foot of the Palisades at a point opposite the elevator on Pier No. 8. This situation is inaccessible for yard track purposes and is of sufficient size to provide for the power house and also for considerable extension. The transmission distance to the elevators from this point is over a thousand

feet, but since 600-volt alternating current is used for distribution this is not prohibitive. The distance to the marine repair shop at the north end of the yard is about half a mile, while the distance to the depot at the south end is over 3500 feet.

The power house is an exceptionally well-designed structure of steel and brick, divided longitudinally into an engine room located on the river side and a boiler room on the west side. There is a 12-ft. high basement under the engine room for steam piping and auxiliary equipment, while under the operating floor of the boiler room there is a 10-ft. high basement for the ash conveyor system. Concrete enters largely into the construction of the building, the wall and engine foundations and the floors being of this material. The entire main roof and the roof of monitors are constructed of 3-in. concrete slabs reinforced with No. 16 galvanized iron wire. The most notable feature of the power house construction is that the floor of the basement is at ground

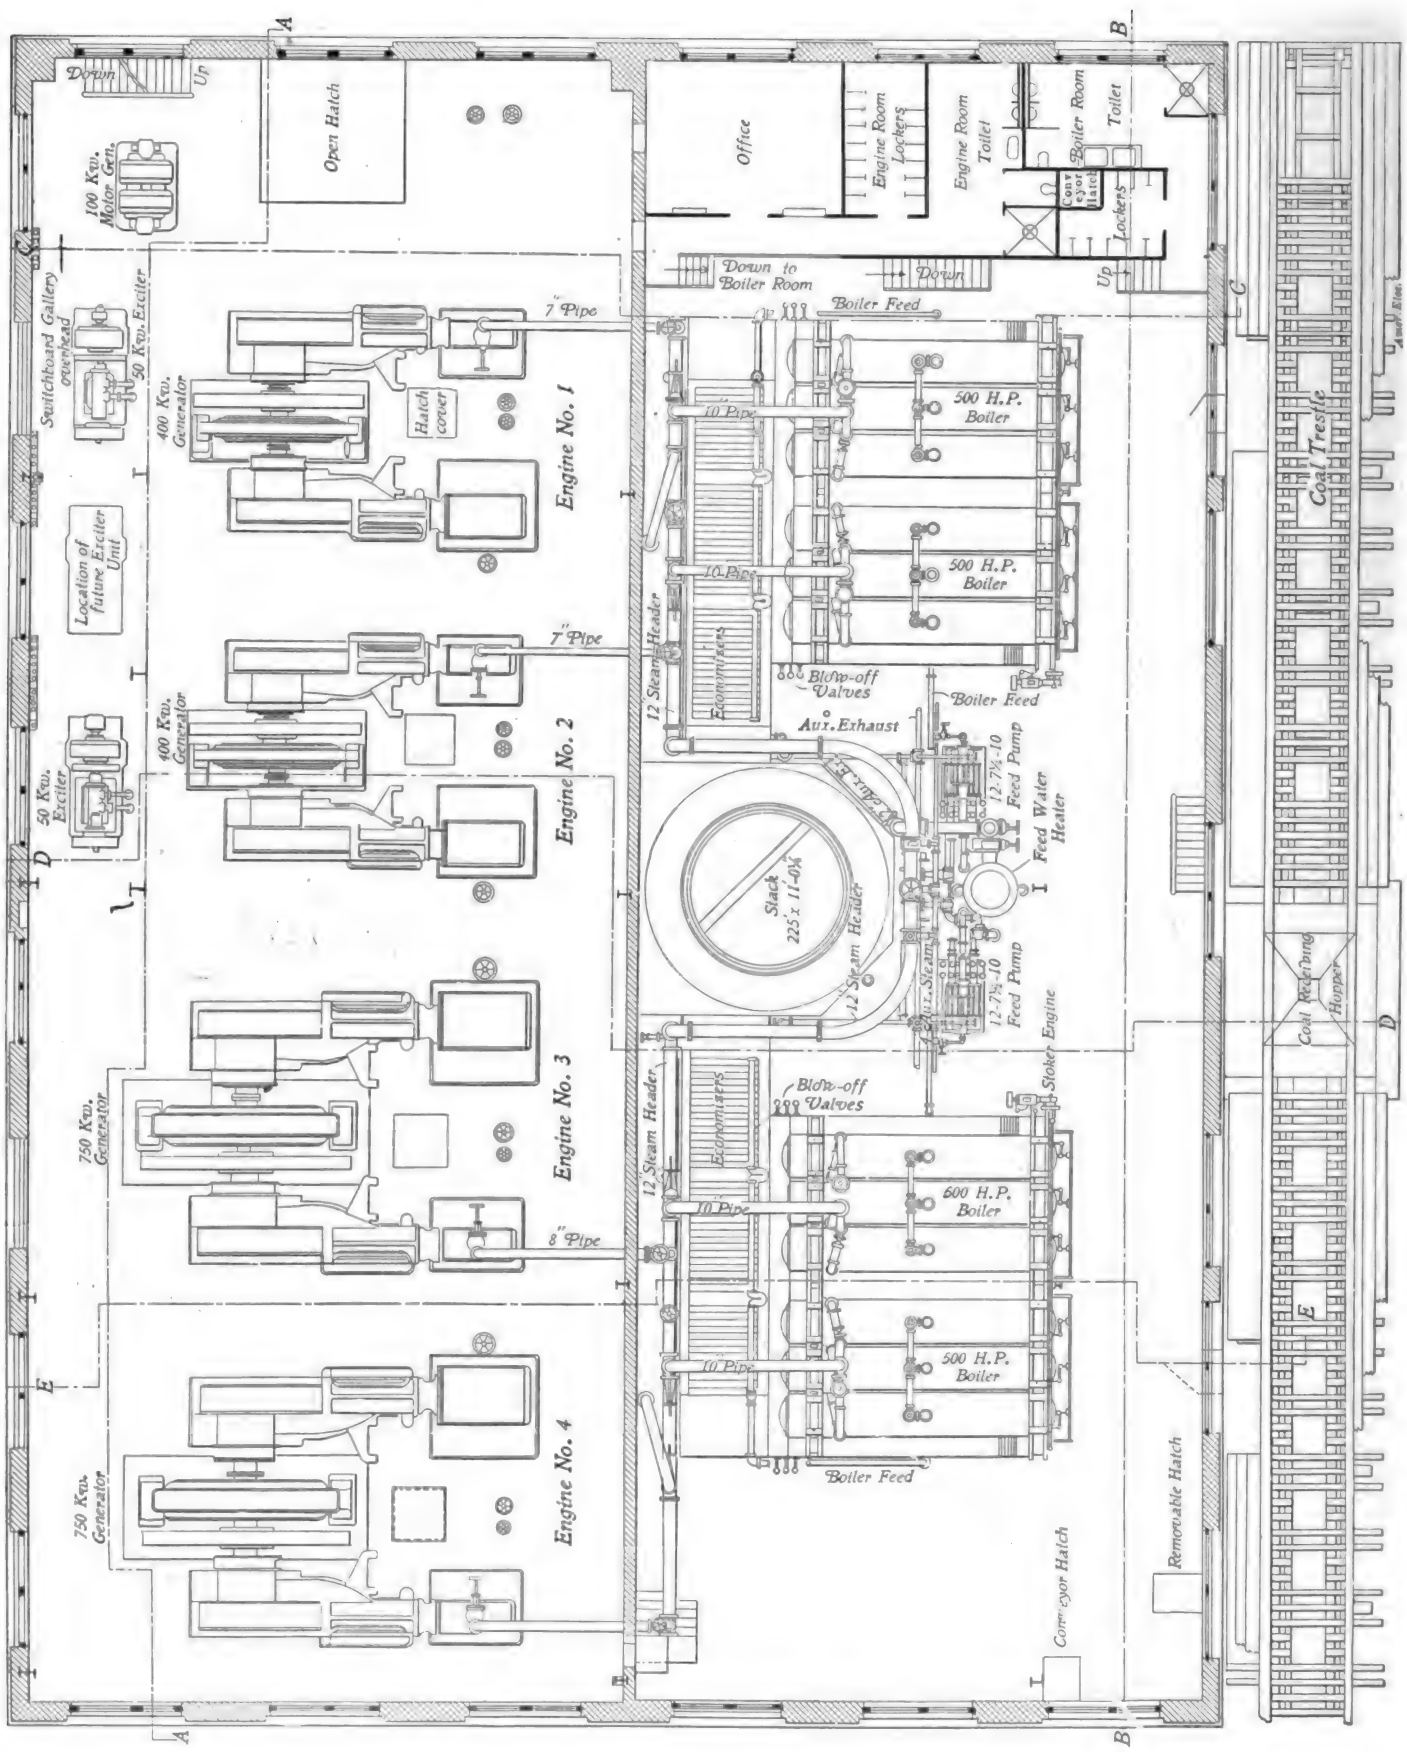

FIG. 2.—PLAN VIEW OF THE ENGINE AND BOILER ROOMS OF THE NEW YORK CENTRAL TERMINAL POWER PLANT AT WEEHAWKEN, N. J.

level. This not only renders the basement light and conveniently accessible, but also permits of its being well ventilated and dry, a point often overlooked in many power plants.

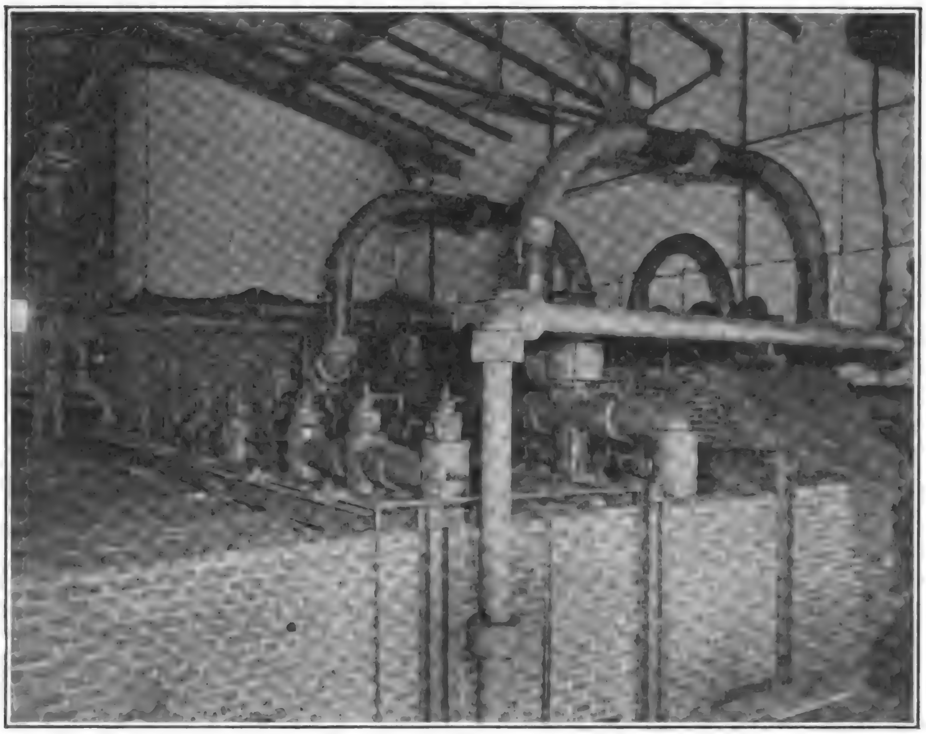

FIG. 3.—STEAM PIPING ABOVE BOILERS.

The boiler equipment consists of four 500-h.p. horizontal water tube boilers set in two batteries of two each, one on either side of the chimney. The boilers were built by the Altman & Taylor Machinery Company, Mansfield, Ohio, and each is equipped with a Foster superheater supplied by the Power Specialty Company, of New York City. The boilers are carried upon wrought-iron supports independent of the brickwork. Other details of the boiler equipment and superheater are given in the following table:

BOILERS.

Nominal Horse Power	500 H. P.
Heating Surface	5,000 sq. ft.
Working Pressure	150 lbs.
Test Pressure after Erection	200 lbs.
No. of Sections	21
No. of Tubes	252
Kind of Tubes	"Knobbled," Hammered Charcoal Iron.
Diameter of Tubes	4 inches
Length of Tubes	18 ft.
No. of Steam Drums	3
Length of Steam Drum	23 ft. 3⅝ ins.
Diameter of Steam Drum	36 ins.
Thickness of Steam Drum Plate	⅜ in.
No. of Mud Drums	1
Diameter of Mud Drum	12 ins.
Length of Mud Drum	12 ft. 6 in.
Thickness of Mud Drum Plate	1¼ ins.
Size of Steam Opening	10 ins.
Number and Diameter of Dry Pipes	3—5 in.
Outside Dimensions of Setting	23 ft. 3 ins. by 15 ft.
Maximum Height of Boiler Above Floor Level	18 ft. 3 ins.
Shipping Weight per Battery	196,000 lbs.

SUPERHEATERS.

Type	Flue Fired
Square Feet of Superheating Surface	1,250 sq. ft.
No. of Tubes	24
Diameter of Tubes	4 inches
Shape of Tubes	⊃
No. of Sections	3
Diameter of Connections to and from Superheater	3—5-in. pipes.

The boilers are equipped with safety high and low-water alarms, which, together with other boiler fittings, are finished in polished brass. The feed and other auxiliary pipe connections are of heavy brass and the blow-off piping is fitted with flange connections. The feature of the boiler and superheater construction is that all joints are made metal to metal, without packing of any kind. The superheaters are located in the setting above the water tubes and form an integral part of each boiler. They are provided with proper connections for by-passing, and are designed to raise the temperature of steam delivered from each boiler at its rated pressure of 150 pounds per square inch to 550° F.

Roney stokers were installed by Westinghouse, Church, Kerr & Co., and each pair of stokers is operated by a Westinghouse special stoker engine. With coal supplied in proper size and with proper firing, the stokers are guaranteed to consume the coal completely and smokelessly. Other information regarding the stoker equipment is contained in the following table:

STOKERS.

Type	Roney Overfeed
Width, Over All	12 ft. 6 ins.
Length, Over All	8 ft. 2 ins.
Grate Area	112 sq. ft.
Weight, Each	21,600 lbs.
Size of Stoker Engine.	4½ in. cylinder diameter, and 4-inch stroke
Horse-power of Stoker Engine, at 80 lbs. steam pressure	5 H.P.
Horse-power Required to Operate Each Stoker,	1 H.P.
Draft Required by Stoker, inches of Water	⅜
Draft Required at 150 per cent. Overload, Inches of Water	½
Rating, Coal per sq. ft. of Grate per Hour	15 lbs.
150 per cent. Overload Rating, Coal per sq. ft. Grate per Hour	22 lbs.

Two fuel economizers, made by the Green Fuel Economizer Company, Matteawan, N. Y., are installed in the smoke flues at the rear of the boilers. Each unit consists of eight vertical cast-iron tubes con-

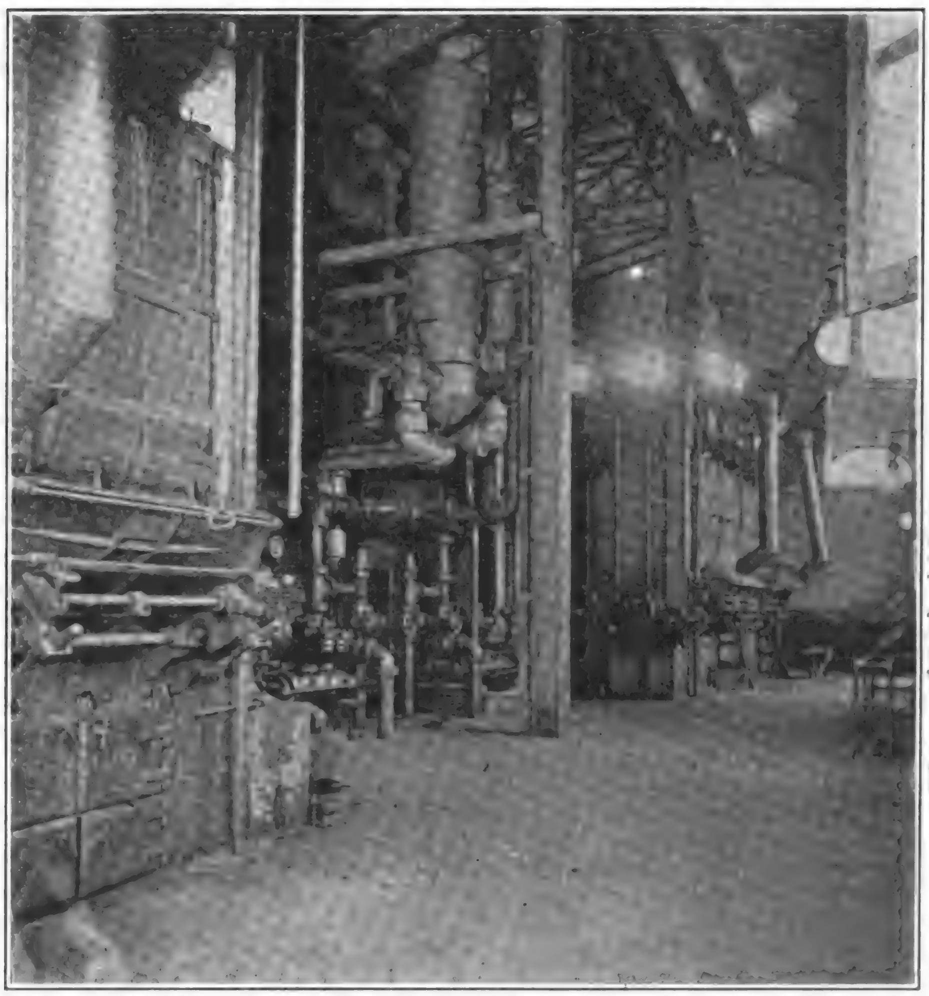

FIG. 4.—BOILER ROOM OF THE NEW YORK CENTRAL TERMINAL POWER STATION.

nected to headers at top and bottom, each row forming a section. The feed-water enters at the cooler end of the flue and leaves at the end nearest the end of the boiler. The usual scraping devices are employed for removing soot from the tubes, and these are driven by three-phase alternating-current induction motors. The principal dimensions of the economizers are tabulated below:

ECONOMIZERS.	
No. of Tubes in Each Section	8
No. of Sections in Each Economizer	44
Length and Diameter of Tubes,	10 ft. by 3⅞ ins. diameter
Total Heating Surface of Each Economizer,	4,576 sq. ft.
Power Required to Operate Scrapers	2 H.P.
Size of Scraper Driving Motors	2 H.P.
Test Pressure for Economizer and Fittings,	350 lbs. Hydrostatic

The stack is of the radial brick type and of ample size to handle normal and 50 per cent. over loads on the present boiler equipment and the two additional boilers for which space is reserved. It is 225 feet high with an internal diameter of 10 feet, but is proportioned for an increase of 50 feet, or 275 feet future height. The base is square, but changes to half-octagonal above the boiler room floor. The round section of the chimney begins just above the economizers. The chimney was built by the Alphons Custodis Chimney Construction Company, New York.

A complete system of conveyors and elevated storage hoppers is provided for handling and storing coal and ashes. A transverse belt conveyor carries the coal from the receiving hopper, and a longitudinal bucket conveyor elevates it to the storage bins above. The system has a capacity for handling 30 tons of coal per hour. A coal trestle is provided at the rear of the building, next the Palisades, by means of which carloads of coal are dumped directly into the receiving hopper and crusher. The pockets for the coal are of steel construction; these are 13½ x 15 feet square at the top, and the chute opening at the bottom is 19 feet above the boiler room floor. The ash pockets are of similar construction, but instead of slanting toward the boilers they slant toward the outside wall so as to deliver ashes into the cars on the trestle outside. The hoppers are carried partly by the side wall and partly by steel columns rising at the boiler fronts and extending to the roof trusses. The total storage capacity is 140 tons of coal, and the ash hoppers are designed to take care of three days' accumulation. The entire system is automatic in its operation.

FIG. 5.—VIEW OF STATION SHOWING CABLE TOWER AND CONDENSER.

Coal is dumped direct from the cars into the receiving hopper, whence it passes into a large coal crusher capable of taking care of 30 tons of coal per hour. From the crusher the coal is delivered into the conveyor system consisting of a belt conveyor running transversely a distance of 18 feet and a bucket conveyor which receives the coal from the belt conveyor and carries it to the storage pockets. The belt conveyor is 18 inches wide and is designed for a belt speed of 400 feet per minute. The main bucket conveyor is of the usual link type. Automatic trips are located over the storage pockets to dump the buckets wherever desired. A reversible variable-speed, three-phase alternating-current motor is used to drive the bucket conveyor, while the belt conveyor and coal crusher are driven through a counter shaft by a variable-speed, three-phase non-reversible, alternating-current motor. The ashes are taken directly from the ash-pits by the main bucket conveyor, an apron being provided to permit of their being scraped into the passing buckets. The entire conveyor equipment, including the crusher, was furnished by the Exeter Machine Works, of Pittston, Pa.

The boiler feed and blow-off piping have been carefully designed, so that troubles from leakage of blow-off valves are provided against, and the possibility of shut down of any boiler, due to lack of feed-water supply, is eliminated by a duplicate system of feed piping. The boiler-feed piping system is carried entirely in the basement below the boiler-room floor. A duplicate source of water supply for the boiler feed pumps is provided at the southwest corner of the boiler room basement, where connections are made with the high and low-pressure water mains of the city of Weehawken, N. J. Duplicate suction connections lead from Worthington water

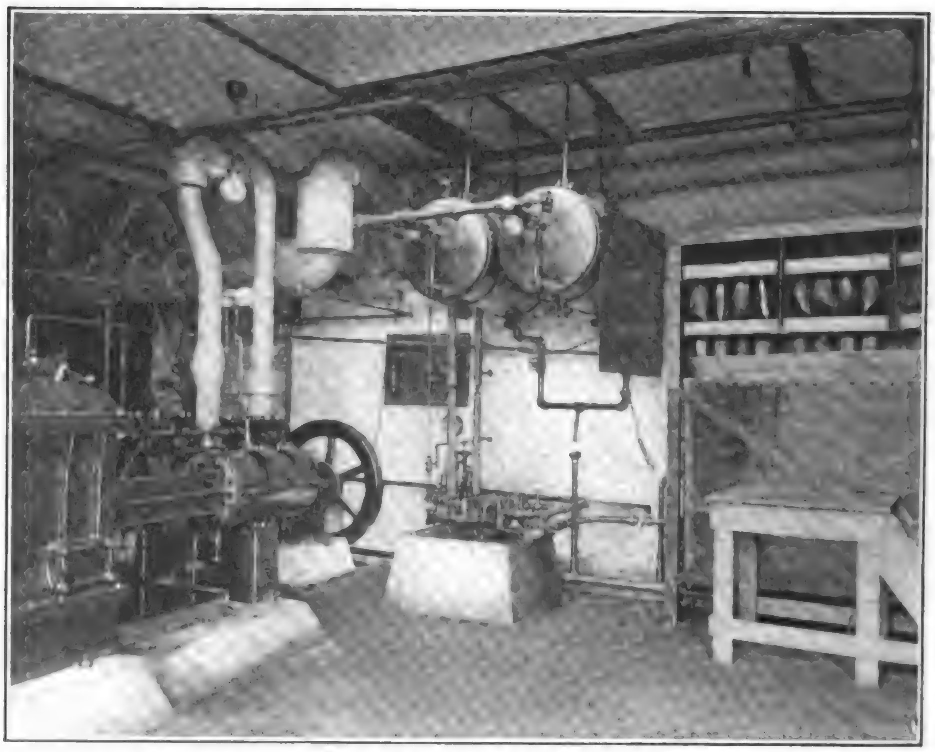

FIG. 6.—CONDENSING AND OIL FILTERING OUTFIT IN BASEMENT.

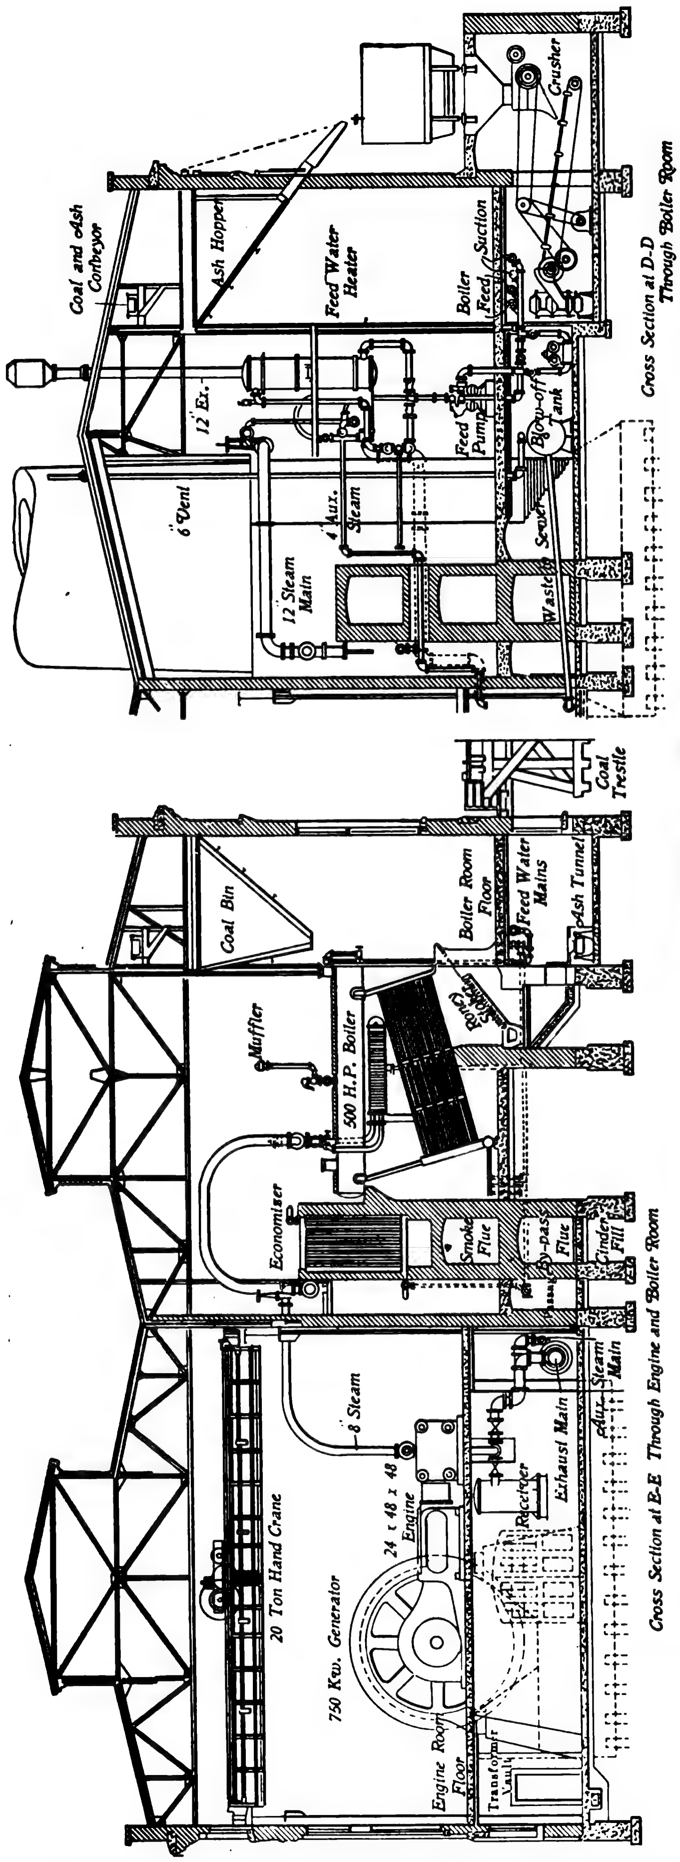
meters to the feed pumps. These pumps deliver through the feed-water heater to the economizers, thence to duplicate 4-inch feed mains, from which connections are made to the boilers. The feed enters at the base of each of the three steam drums of each boiler.



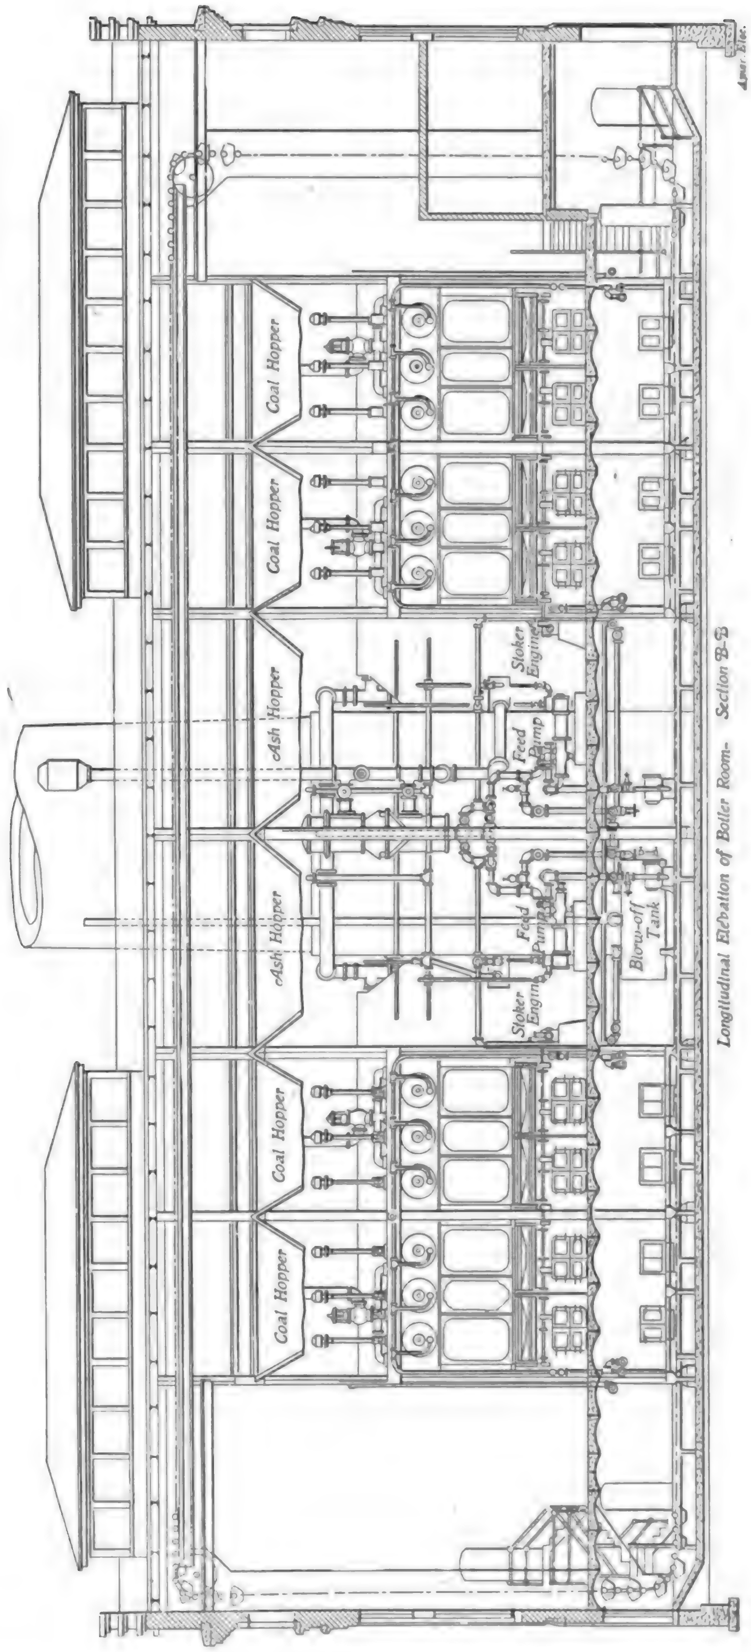


Fig. 7.—Cross-Sectional View of Station and Sectional and Longitudinal Elevation of Boiler Room.

The feed-water connections are very flexibly arranged. Either the feed-water heaters or the economizers may be by-passed, or both may be by-passed at once, so that in this way either one or both of the feed pumps may deliver either cold or hot water to the boilers through either leg of the duplicate system of piping. Galvanized mild steel pipe, tested at 400 pounds hydrostatic pressure for 48 hours, is used throughout the entire feed system, and relief valves are located in the delivery of each pump, so that excessive pressure in the feed system, due to a delivery pipe from the pump being clogged, is prevented.

Two boiler feed pumps are provided, each of which is capable of feeding the entire equipment. The pumps are Worthington outside-packed plunger pressure pumps, with "pot" valves fitted to handle cold water. Each has steam cylinders 12 inches in diameter and water cylinders 7½ inches in diameter, with a common stroke of 10 inches. The capacity of each pump is 22,000 gallons of water per hour delivered against a pressure of 300 pounds at a piston speed of not over 100 feet a minute. The pumps are located on the boiler room floor adjacent to the base of the stack. The feed-water heater is located directly above the feed pumps, upon a special steel platform, as shown in Fig. 7. This heater is a vertical Wainwright enclosed-tube type heater and is capable of raising the temperature of 70,000 pounds of feed water per hour from 40° to 100° F., with 7000 pounds of exhaust steam at atmospheric pressure. The blow-off piping system includes, besides the three blow-off connections from each boiler, a blow-off from each economizer and one from the feed-water heater. These all empty into a special blow-off tank through a 4-inch blow-off main; a 6-inch overflow leads from this tank to the sewer. The blow-off connections from each boiler consist of three 2½-inch asbestos-packed blow-off cocks at the mud drum, these cocks being connected to the blow-off main through a 2½-inch Cadman angle blow-off valve. The blow-off piping is flange-connected and tested under high pressure. Tees and crosses are used in place of elbow fittings wherever possible, blank flanges being applied to the vacant sides, thus permitting ready access for cleaning out pipes. The blow-off tank is located beneath the feed pumps and consists of a horizontal cylindrical tank 4 feet in diameter and 11 feet long. It is designed to withstand a pressure of 200 pounds per square inch and is fitted with two inlets on the top for receiving the blow-off connections from the boilers, and a 6-inch pipe leads from the top of the tank to the roof. This serves as a vapor discharge to atmosphere. A 6-inch overflow also leads from the side of the tank to the sewer.

Figs. 2 and 7 show plan and elevation views of the power house as well as the steam piping system. The main system is laid out with great care to provide for expansion, and lap-welded mild steel pipe is used throughout. The system begins at the 10-in. emergency and hand-stop valves on the connections from the three superheaters of each boiler and lead through easy bends to a 12-in. steam header on the boiler room side of the division wall, from which connections are made to the engines and auxiliary steam pipe system. The steam header is carried on a pipe gallery in the rear of the economizer setting at a height of 19½ feet above the boiler room floor. Where the gallery is interrupted by the base of the stack, the header is carried around in a loop with double-elbow vertical off-set connections at each end. The header is arranged in sections, so as to permit of individual connections between adjacent boilers and engines. There are four sections connected by stop valves, and each of the sections connect with one boiler and one engine. This makes a flexible and convenient arrangement, since the equipment can be cut into four practically separate and individual power plants. The header is fastened rigidly at the middle point of each portion of the gallery and allowed to expand in either direction. Provision is made for expansion at intermediate points of support. Ten-inch stop valves are provided in each boiler connection, one at the boiler outlet and another close to the header. Two valves are provided in each engine connection, one the engine throttle and the other an angle valve just above the header. All connections are made to the header at the top side. The connecting pipes are arranged with long radius bends, the sharpest of these being of 4-foot radius, which lead from each section to the auxiliary steam header in the basement. Drainage is carefully provided for in the entire system, and condensation is minimized by nonconducting coverings on all steam pipes.

An auxiliary steam piping system is provided to supply the pumps, stoker engines, exciter engines and condenser pumps. This auxiliary header extends through the engine room basement at the rear of the large exhaust header. It is made up of two sections of 8-inch pipe, each fed from the main steam header by 4-foot radius bends; both sections are joined together at the middle by a long radius bend of 6-inch pipe to provide for expansion. A 4-inch branch supplies the pumps in the boiler room, and a 6-inch loop extends across the engine room basement to supply the exciter engines and condenser pumps. Auxiliary connections are also provided from this header to the low-pressure cylinders of the large engines. The auxiliary header is divided into two sections by a stop valve so as to eliminate a complete shut down in case of accident.

The main engine equipment consists of two 1200-h.p. and two 650-h.p. compound condensing Corliss engines direct connected to three-phase, alternating-current generators. They are of the heavy-duty cross compound type, with receiver, and the generators are located between the cranks. The engines are of the improved horizontal Corliss design recently brought out by the Westinghouse Machine Company. They operate at a throttle steam pressure of 140 pounds and at an exhaust vacuum of 25 inches. They are designed with particular reference to parallel operation and have similar characteristics of speed regulation. The engine guarantee provides that when the load is suddenly thrown on from no-load to full-load the engine shall not vary in speed sufficiently to permit the generator to run ahead or fall behind a machine running at absolutely constant speed of the same number of revolutions per minute, by more than .15 of one degree. The important dimensions of the engines are presented in the following table:

TABLE I.—ENGINE DIMENSIONS

	1200 H.P.	650 H.P.
Diameter of high-pressure cylinder	24 ins.	20 ins.
Diameter of low-pressure cylinder	48 ins.	40 ins.
Length of stroke	48 ins.	42 ins.
Speed, normal full load	94 rev. per min.	120 rev. per min.
Horse-power, indicated, normal	1,200 h.p.	648 h.p.
Cut off, high-pressure cylinder, normal	26 per cent.	
Cut off, low-pressure cylinder, normal	37 per cent.	
Cut off, high-pressure cylinder, maximum	75 per cent.	
Diameter of crank shaft, center	21 ins.	17 ins.
Diameter of crank shaft, bearings	18 ins.	15 ins.
Diameters of piston rods, each	5 ins	4½ ins.
Face of crosshead gibs	22 ins. long by 11 ins. wide	
Crosshead pins	length 9 ins.; diameter 8 ins.	length, 7¼ ins.; diam., 6¼ ins.
Crank pins	length 9 ins.; diameter 9 ins.	length, 7¼ ins.; diam., 7¼ ins.
Main bearings	length 36 ins.; diameter 18 ins.	length, 30 ins.; diam., 15 ins.
Length of connecting rods, center to center	132 ins.	115½ ins.
Diameter of connecting rods, at center	6 ins.	5 ins.
Diameter of flywheel	216 ins.	180 ins.
Width of face of flywheel	17 ins.	14 ins.
Weight of flywheel	60,000 lbs.	40,000 lbs.
Thickness of piston, H. P. Cylinder	12 ins.	10 ins.
Thickness of piston, L. P. Cylinder	24 ins.	20 ins.
Diameter of main throttle valve	8 ins	7 ins.
Diameter of main exhaust valve	18 ins.	14 ins.
Length of engine, over all	33 ft. 6 ins.	28 ft. 8 ins.
Width of engine, over all	27 ft.	21 ft.
Height of engine, over all	12 ft.	10 ft.
Total weight of engine, complete	280,000 lbs.	195,000 lbs.

The governors are of the safety fly-ball type and control the cut-off in both the high and low-pressure cylinders. The speed control is such that speed variation does not exceed 2 per cent for a 5-pound change in steam pressure above or below normal, and 3 per cent when full rated load is instantly thrown on or off. In addition to the safety feature of the governor, the engines are fitted with Monarch safety stops, which are arranged to automatically cut off the steam supply in case the engine speed increases more than five revolutions above normal. The engines operating the exciters are 90-h.p. vertical cross-compound non-condensing engines of standard Westinghouse design. Each is direct connected to a 50-kw., direct-current generator and operates at the same steam pressure and superheat as the larger engines.

The cylinders of all the engines are designed to permit two reborings, and expansion and contraction are carefully provided for in their construction. Metallic packings are used throughout and each cylinder is covered with magnesia non-conducting covering and lagged with polished sheet-iron lagging with copper corner strips. Snifting valves are provided on each cylinder and connections are also provided at each end for indicators.

The oiling system is quite complete. A complete automatic closed oiling system is provided on each engine, in addition to triple sight-feed lubricators and hand cylinder oil pumps upon each cylinder. Drip pans and return pipes collect and lead the

used oil back through an oil filter and purifier to a 150-gallon return tank, whence it is pumped to an elevated 150-gallon supply tank. A complete piping system leads from this tank to the various sight-feed oil reservoirs and to all other parts of the machinery requiring lubrication.

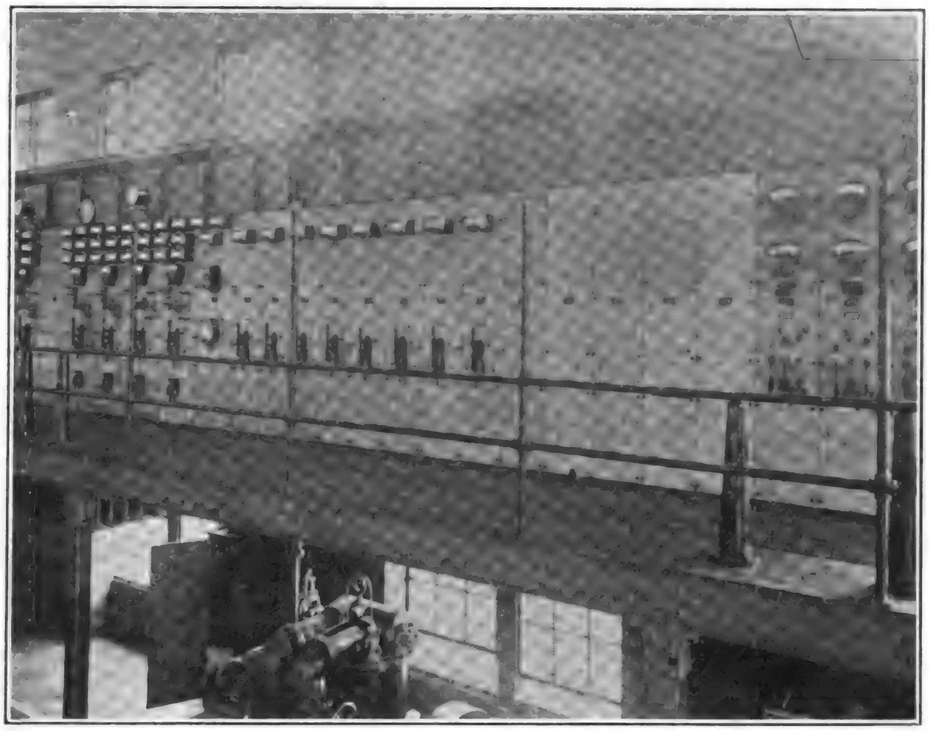

FIG. 8.—PARTIAL VIEW OF SWITCHBOARD.

Two systems of exhaust piping are installed; one taking care of the exciter engines, condenser pumps and boiler-feed pumps, and the other taking care of the exhaust from the main engines. The former delivers to the atmosphere through the feed-water heater, while the latter delivers to the condenser. The main exhaust is made up of two sections, one of 20-inch and the other of 30-inch cast-iron pipe running horizontally through the engine-room basement to the condenser connection outside the southern end of the building. The condenser, which is shown in Fig. 5, is of the barometric central-jet type. It is situated over the hot well and is connected to a 30 x 20 x 20 x 24-inch cross in the exhaust pipe riser, on the top side of which cross is a 24-inch atmospheric relief valve. The condenser has two cast-iron cones, each flanged for a 20-inch exhaust connection, and it also has a 10-inch cold-water injection connection. A dry air connection is provided, and a 10-inch tail pipe extends from the condenser chamber to the hot well. Circulating water is furnished by two steam-driven centrifugal pumps, which take their suction through special strainers and foot valves from an intake well receiving water from the Hudson River. The suction connections are of 12-inch, and the delivery of 10-in. pipe. A dry vacuum pump is provided for removing the accumulated air from beneath the condensing cones. The capacity of the condensing outfit is sufficient to take care of 55,000 pounds of exhaust steam and to maintain the vacuum when the generators are running at their full rated load. The capacity of the circulating pumps is sufficient for condensing all the steam and also provides for heavy overload.

The engine room is provided with a 20-ton single-trolley traveling crane, having a 50-ft. span. This was furnished by the Alfred Box Company, Philadelphia, Pa., and is operated by hand power from a platform suspended from the bridge.

FIG. 9.—MOTOR-GENERATOR AND EXCITER UNITS.

The electric equipment at the power house comprises two 750-kw., 600-volt, three-phase, 25-cycle, alternating-current generators built by the Bullock Electric & Manufacturing Company, two 400-kw., 2300-volt, three-phase, 60-cycle alternators built by the General Electric Company; one 100-kw., 2300-volt, 60-cycle, 600-volt, 25-cycle motor-generator; two 50-kw., 250-volt, direct-current exciter units, one 20-h.p. and one 15-h.p., 220-volt induction motors, one 5-h.p. and four ¼-h.p., direct-current motors. Nineteen 110-volt, alternating current, and eight 220-volt, direct-current arc lamps, together with 185 16-c.p. incandescent lamps are used in lighting the station.

The switchboard is located on a gallery in the southeast corner of the engine room, as shown by Fig. 1. It is of standard General Electric make and is made up of 28 panels. Their order from right to left is as follows: Three exciter panels, five blank panels and eight feeder panels. The first of these feeders is blank, the next feeds Piers 2, 3, 4, ice house and transfer bridges for car floats; the next supplies power to the coaling station and the next furnishes power to the central station auxiliaries. Then follow lighting panels, one feeds the marine repair shop and new ferry house, another serves Piers 2, 3, 4, transfer bridges, old grain elevator, yards and signal tower, another lights the passenger station, engine and gas house, coaling station and milk sheds, while the last serves the power station. A totalizing panel for the 2300-volt current comes next, followed by four panels, two of which are devoted to the motor-generator set and two to the 2300-volt generators. The next panel is vacant and is followed by two 600-volt generator panels and one totalizing panel for the 25-cycle current. The last three panels on the board are feeders supplying the new grain elevator with electricity for light and power.

The circuits supplying light and power to the new grain elevator run across the yard in underground conduit to a manhole in front of Pier 8 and then continue parallel

to the Hudson River to a manhole in front of Pier 7, whence the wires lead to the elevator.

The elevator equipment consists of twenty-three 100-h.p., 550-volt, three-phase, 25-cycle induction motors driving elevator legs; two 75-h.p., seventeen 40-h.p., two 10-h.p. and one 5-h.p. induction motors with their starting compensators, fuse casings, etc. These are with few exceptions of General Electric make. Seventy-eight 32-c.p., three hundred and thirty-five 16-c.p. and ninety-six 8-c.p. incandescent lamps are used for lighting this elevator and two 4000-watt and three 2000-watt electric heaters are also installed.

The other feeders for lighting and power are carried from the switchboard in lead-covered cables of No. 2 B. & S. wire to the top of the cable tower shown in Fig. 5, whence they are distributed on overhead pole lines to the various points of current consumption. The main pole line skirts the foot of the Palisades and branches, carrying sub-feeders cross the yards to the water front wherever necessary.

The motor equipment along the water front and in the yards is as follows: At the transfer bridges for car floats two 10-h.p., 440-volt induction motors are used in operating the aprons; the coaling station is equipped with a 15-h.p. induction motor, and the ice house has one 3-h.p. and one 5-h.p. induction motor for operating an ice crusher, etc. Piers 1 and 2 have each two 5-h.p. induction motors for operating bag and sack conveyors and one 1-h.p. motor. Pier 4 is equipped with one 1-h.p. and four 5-h.p. induction motors; it is lighted by forty-six arc lamps and four incandescent lamps.

Piers 2 and 3 have 336 and 273 incandescent lamps, respectively, with an arc lamp outside each pier. Enclosed arc lamps are used throughout the yards, at the marine repair shop, ferry house, yard master's office, ice house, transfer bridges, marine and locomotive coaling station, ferry bridges, passages, waiting rooms, racks, railroad platforms, immigrant waiting room and express sheds. A small motor-generator is located in the railroad station to furnish 220-volt, direct current for operating fan motors in the restaurant.

The transformer equipment throughout the yard is as follows: At the ferry house Pier 17, one 7½-kw.; marine repair shop, one 15-kw. and three 30-kw.; grain elevator, Pier 8, one 25-kw.; Pier 4, two 15-kw. and three 7½-kw.; shop and signal tower, one 10-kw.; Pier 3, one 30-kw. and three 3-kw.; paint shops, one 5-kw.; ice house, one 5-kw.; Pier 2, one 30-kw. and three 10-kw.; transfer bridge, three 5-kw.; milk platform, one 10-kw.; coaling station, three 5-kw.; engine house, one 5-kw.; sub-station near ferry, one 100-kw.; marine coaling station, one 3-kw. and three others.

We are indebted to Mr. Edwin B. Katte, electrical engineer of the New York Central & Hudson River Railroad, who designed the plant, and to Mr. J. Stehlin, mechanical engineer, for courtesies extended in the preparation of this article.

METALLIC PACKINGS.

BY R. T. STROHM.

Metallic packings for the rods and stems of steam engines, compressors and the like, are intended not only to fulfil all the purposes for which fibrous packings are used, but also to give increased durability. Being made of metal, it is reasonable to suppose that the amount of wear between the packing and the rod will be considerably less than in the case of fibrous packing. This conclusion is borne out in practice, since a rod which is properly packed with a metallic packing will give a much longer service, before repacking, than if it were supplied with the ordinary fibrous kind.

But, further than this, the metallic variety is also intended for situations and conditions under which the ordinary packings

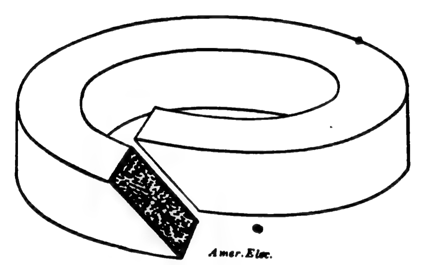

FIG. 1.

would fail entirely, or at best have only a short and unsatisfactory life. Engines using highly superheated steam or even saturated steam of extremely high pressure, present such conditions. The vegetable nature of most of the fibrous packings makes them readily susceptible to the action of steam at high temperatures. It is true that fibrous packings composed largely of asbestos have been put forward for high-pressure work, and have met with success. But there is this point to be remembered: No fibrous packing can preserve its original inherent lubricating qualities for any great length of time when subjected to high pressures and temperatures. And this accounts for the burning out of some fibrous packings. Once the material has lost the greater portion of the lubricant with which it was originally saturated, it will grow dry and hard, and repacking will be necessary to prevent damage to the rod.

With metallic packing there is no need of anxiety on the part of the engineer lest the packing char or burn. Its metallic nature prevents such action. However, it does become necessary to furnish continuous lubrication so that the friction with the rod shall be reduced to a minimum, the wear lessened, and the life of both rod and packing extended. In this case, there is no reliance, for continuous operation, upon the lubricant contained in the packing when first put in place. It is to be understood that the foregoing remarks apply to those forms of packing built up of solid metal rings, and not to the plastic varieties.

In Fig. 1 is shown a form of metallic ring packing, made up in rings of the proper size to fit the rod and stuffing-box. These rings are placed one on top of the other until sufficient to fill the stuffing-box properly, after which the gland is tightened, as in the case of fibrous ring packings.

The material of which the ring is composed is a soft anti-friction metal, which, after being drawn into fibres, is wound into rings of approximately the size and shape required and then saturated with graphite and high-grade mineral oil. The rings are next placed in molds and heavy pressure is put upon them to bring them to the exact size, after which they are covered with a thin coat of rubber. This rubber simply holds the rings in shape while they are being handled, and is quickly worn off on the side next the rod, leaving a bright, soft, oily, metallic surface against the rod. The ring is elastic, and, being of a metallic alloy which melts at more than 500° F., there is no danger of its failing even under extraordinary conditions of pressure and temperature.

There are a number of packings of this nature, differing simply in the form in which they are sold. In one case, the babbitt is fused with graphite so as to form a spongy mass, into which oil is mixed until a plastic substance is formed which may be pressed easily into any stuffing-box. In another, the mixture has a granular appearance, and is put up in long, narrow cotton bags, much resembling sausages. Lengths are cut from these to form rings which are applied in the same way as rope packings. The cotton soon wears away, leaving the composition next the rod.

In Fig. 2 is shown a form of wedge packing. Each of the rings *A*, *B*, *C* and *D* is made in two pieces, molded to the wedge form as shown, with one flat face and one beveled on each. The flat faces of each pair of adjacent rings are placed together, so that when a slight pressure is brought to bear by the gland, the rings slip

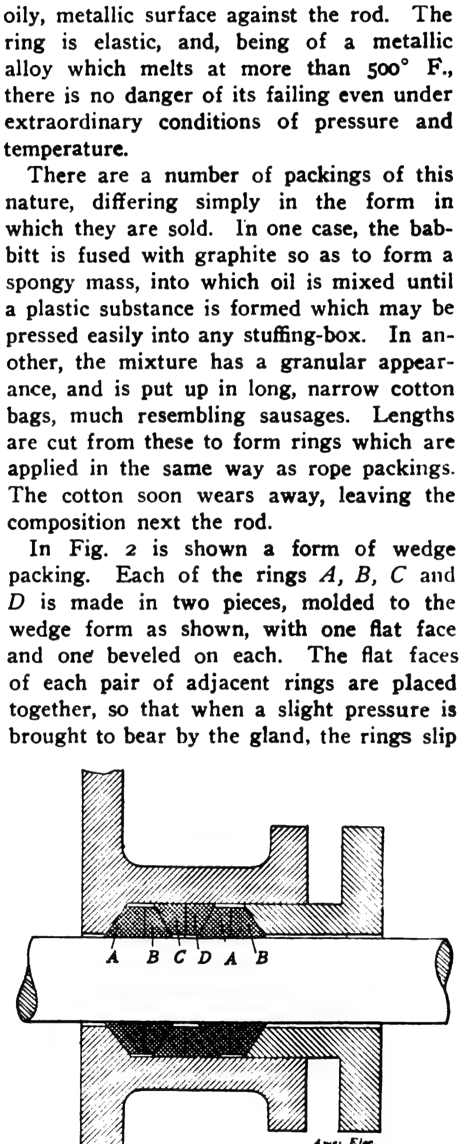

FIG. 2.

along their beveled faces, the rings *A* and *B* being forced against the rod and *C* and *D* against the walls of the stuffing-box. The rings are composed of bearing metal and graphite, and can be made to fit any form of stuffing-box.

A simple form of metallic packing is shown in Fig. 3. It is composed of rings made in halves, which are placed around the rod in such a way as to break joints. The central ring *A* is forced against the rod, and the end rings *B* and *C* against the wall of the box. Thus, the babbitt ring *A* makes the joint. The spaces between and out-

side the rings permit the collection of condensation and lubricants, which are relied upon to keep the packing cool. This is a floating packing, also; that is, it follows the rod when the latter has a slight lateral movement due to imperfect alignment.

The great majority of metallic packings, instead of being either plastic or elastic, are of the solid type, like that illustrated in Fig. 4. This figure shows the packing applied to a rod without making use of the old stuffing-box and gland, which is the manner in which many metallic packings must be applied. The reason is that the construction of the packing is such as to prevent its going into the stuffing-box.

The packing consists of three pairs of

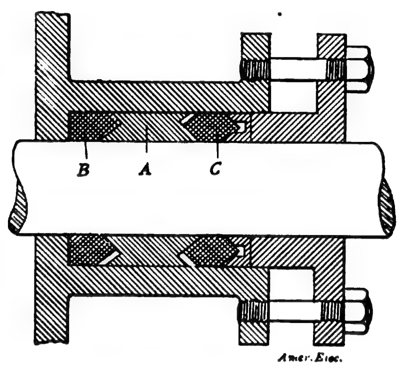

FIG. 3.

rings at *A*, *B* and *C*, each pair contained in grooves in a casing. These grooves are just wide enough to allow the two rings to fit in snugly side by side, and not too tightly to prevent lateral motion. The packing rings thus are floating, that is, moving with the rod, so that if the rod is not centered exactly, or if it is slightly bent, the rings are free to follow it in its lateral movement in the box.

Each ring is composed of three sections, the mode of cutting the ring being clearly shown in Fig. 5. The three segments meet along the faces *A*, *B* and *C*, and, if these lines are prolonged, they will intersect so as to form an equilateral triangle whose center is at the center of the rod. The purpose of this is obvious. Frequently, the

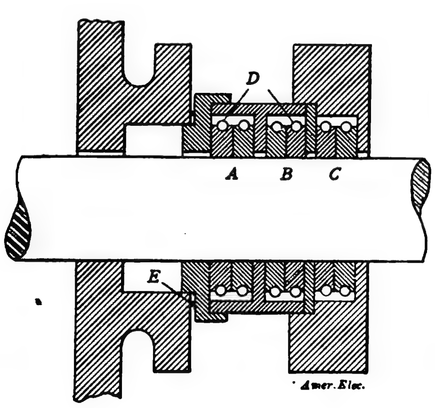

FIG. 4.

rod is not uniform in diameter, or, perhaps, it may be worn slightly oval. If a solid ring were used about the rod, leakage would certainly follow. But, with the three-piece ring, the sections may adjust themselves to the shape of the rod. If the rod diameter increases slightly, the sections are forced apart, sliding upon the flat surfaces *A*, *B* and *C*. This enlarges the triangle formed by these faces, but its center still lies at the rod center.

A spring, *D*, surrounds each ring, lying in

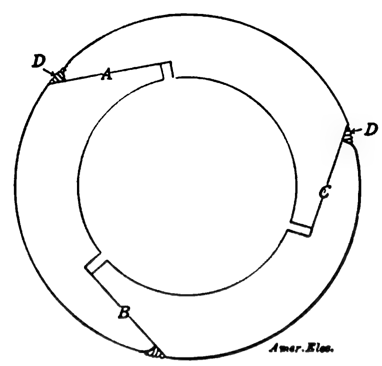

FIG. 5.

a groove cut for it in the back of the ring. It is made of a composition of metals which is unaffected by heat, and it holds the segments of the ring together, close to the rod at all times. The rings themselves are commonly made of soft grey iron, since it meets all ordinary requirements. However, for special conditions, brass and bronze may be used. The casing containing the rings is made of cast-iron, and it is customary to put a lead wire gasket against the flange of the stuffing-box, as at *E*, to prevent leakage past the casing.

The casing containing the packing rings may be made either solid or split in halves. It is evident that if made solid it will be

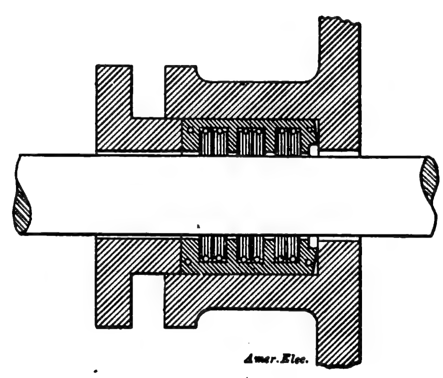

FIG. 6.

necessary to disconnect the piston rod in order to apply the packings. The split case, on the other hand, may be placed on the rod and then bolted together.

A packing of somewhat similar nature is shown in Fig. 6. Here, however, the ordinary stuffing-box is used as a receptacle for the case containing the rings. The rings are laid together in pairs, each pair occupying a separate groove, allowing lateral vibration. Each ring is composed of two pieces, which are dowelled together and surrounded by a spring. In applying the packing, the rings are placed on the rod so as to break joints, the case placed over them and screwed together, and the whole slid along the rod into the stuffing-box. Both the rings and the case are given a coating of cylinder oil while they are being put together, and a lead joint is made between the bottom of the case and the bottom of the stuffing-box.

The packing illustrated in Fig. 7 differs in some of its details from the two just described, although its general arrangement is much the same since it has six rings, in three pairs, placed in casing compartments. The casing, however, is not a single piece, but is made up of several separate parts. The packing rings, also, are different. In each pair there is a broad ring and a narrow ring. The broad ring, shown at *A*, is of three segments, held together by the usual outside spring. But one segment carries the dowel pin *B*, which fits into the opening between two of the segments of the adjacent narrow ring, *C*. This provision assures the placing of the rings of each pair in such relative positions that the points where the segments of one ring meet shall

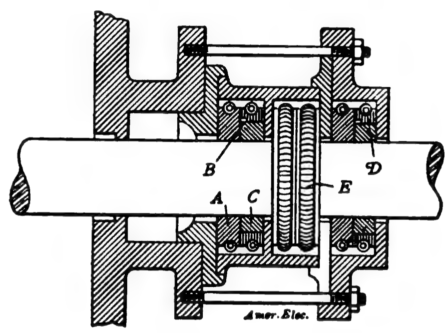

FIG. 7.

come midway between the points on the adjacent ring. The narrow ring *C*, while composed of three parts, is surrounded by an outer or cap ring *D*, which is grooved to contain the spring, *E*. It will be observed that when the packing is applied outside the box, it extends for a considerable distance along the rod. If there is very little clearance between the crosshead boss and the gland, it may be impracticable to use metallic packing of this kind.

Some novel features enter into the construction of the packing shown in Fig. 8. The usual three-part casing is used, containing three pairs of packing rings, which are free to move sidewise in their several

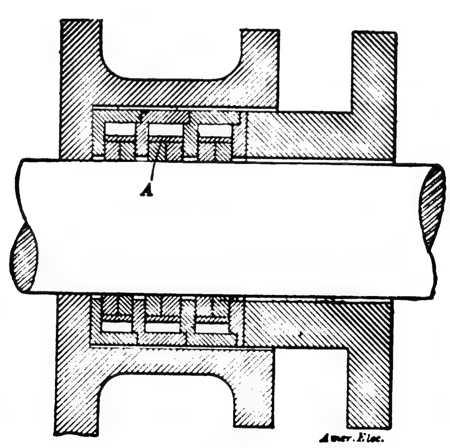

FIG. 8.

compartments. Each one of the rings is divided into three pieces, which do not meet one another when placed around the rod, but are held together by a split ring, *A*, against which press flat springs. This is perhaps more clearly shown in Fig. 9, which represents a section at right angles to the

axis of the rod. In this figure, the three parts of the ring are shown at *A, B* and *C,* surrounded by the split ring, *D.* Between this ring and the solid outer casing, *E,* a number of flat springs, *F,* are placed. The pressure of these springs forces the ring segments tightly against the rod, while the ring, *D,* prevents displacement of the

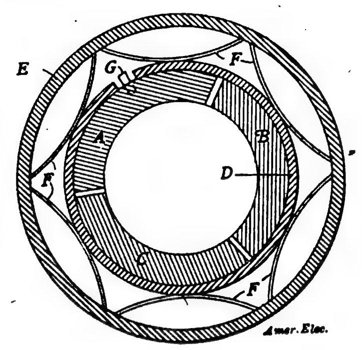

FIG. 9.

pieces. The pin, *G,* which is placed in one of the sections, and extends into the opening between the ends of the split ring, *D,* prevents the rings from turning on the rod, and thus assures the fact that the ring joints of adjacent rings shall always be staggered, thereby avoiding leakage.

Fig. 10 shows a longitudinal section of a packing which presents a number of interesting features. At the bottom of the stuffing-box is a flanged ring, *A,* which serves to hold one end of the helical spring, *B* central in the box, thus preventing its touching the rod and scoring it. This spring presses against the follower plate *C* and thus holds the packing in position. The outer face of the ring plate *C* is beveled and fits snugly against the babbitt packing ring *D.* The latter in turn bears against a smaller babbitt ring *E,* which is beveled at the same angle as *D* along the outer face. Both of the rings *D* and *E* are enclosed by the casing *F.* It is evident that the pressure of the spring *B* is transmitted to the follower *C* and thence to the packing rings, which, because of the wedging effect

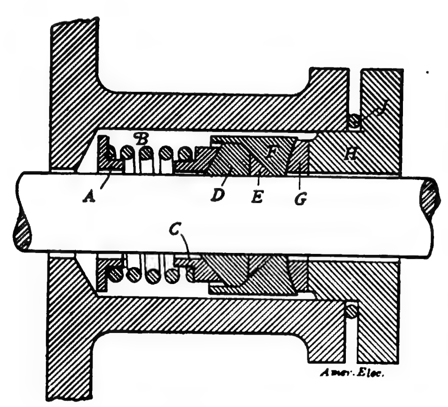

FIG 10.

of the casing *F,* are forced tightly against the rod, sliding inward upon both *C* and *F.* The rings *D* and *E* are split, but their joints are staggered to prevent leakage, a lug on *E* being supplied so as to insure the correct relative positions of these rings. The straight projection or lip at the inner end of the casing *F* is to enclose the ring *D* and receive the follower *C.* The outer end of the casing is given a concave face, which fits upon the convex surface of the ring *G.* The curved surface along which *F* and *G* meet is spherical, and the joint is, therefore, a ball joint, which permits the rod to move somewhat in any direction, laterally, without causing leakage. The joint between the ring *G* and the gland *H* is a ground

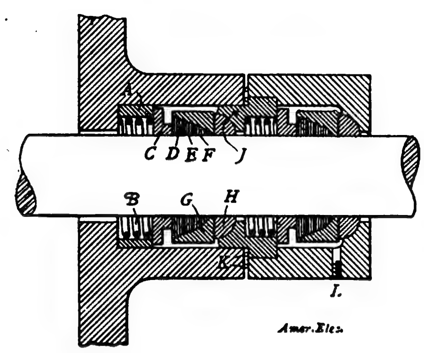

FIG. 11.

joint, to preclude escape of steam. Thus all chance of leakage along the rod is cut off. Between the gland and the flange of the stuffing-box a joint is made with a soft copper wire *J,* thus effectually preventing escape of steam at this point. This packing is not designed differently for each separate case, but is capable of being applied to any engine without necessitating any change in the stuffing-box. This is a point considerably in its favor.

A packing which has great flexibility is shown in Fig. 11. The flat ring *A* is placed at the bottom of the stuffing-box, and inside it the coiled spring *B.* Upon the spring is set the collar or flanged follower *C,* its flange bearing against the soft metal packing rings *D, E, F,* enclosed in the cup *G.* Then a ball ring *H,* whose cross-section is a quadrant, is located with its flat face against the outer end of the cup, and the ball seat, with its concave face, is laid up against the ball ring. This ball seat *J* holds a second spring, which is followed by another series of rings in the same order as previously described. Thus, there are prac-

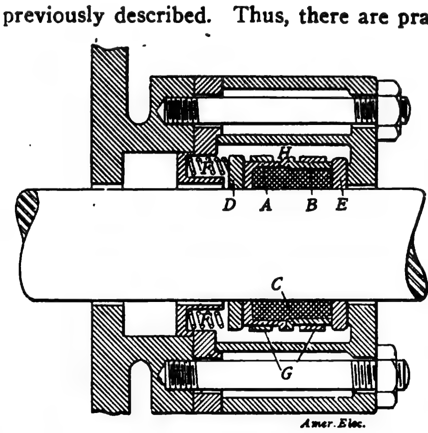

FIG. 12.

tically two sets of packing, one in the stuffing-box and one in the casing outside it.

As in the previous type, the pressure of the spring is just sufficient to hold the parts in place against the friction. The setting of the packing rings against the rod is done by the steam pressure, so that the friction is not the same at all points of the stroke, but varies nearly with the change of pressure in the cylinder. The taper on the inside of the cup *G* serves to force the rings against the rod, when they are acted upon by the steam pressure. The ball joint permits vibration without leakage. A copper or lead wire joint is made at *K* to prevent escape of steam. At *L* is a small hole tapped for the attachment of a drip pipe, by which all moisture of condensation which works out along the rod may be removed. The same hole may also be used for injecting oil into the casing to lubricate the packing. Oiling in this manner gives a bath of lubricant contained in the casing, through which the rod must move. This avoids the unsatisfactory method of lubrication often adopted—dropping oil on the rod just outside the stuffing-box and trusting that it will work its way inward to the packing.

The babbitt rings *D, E, F,* which come in contact with the rod, are cut in halves, with perhaps a sixteenth of an inch between their ends. When the rings have conformed to the shape of the rod, the ends of the rings will soon meet, which prevents their being jammed further into the cup, thereby prolonging their life, without spoiling the tightness of the joint.

Another packing applied in an external casing is lilustrated in Fig. 12. The packing rings *A* and *B,* lined with babbitt *C,* are held between the two collars *D* and *E.* The faces of these collars are at right an-

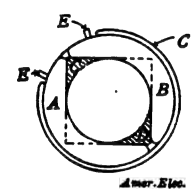

FIG. 13.

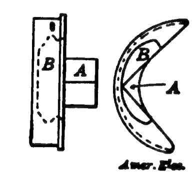

FIG. 14.

gles to the rod axis, and hence the packing rings are free to slide from side to side. The springs *F, F,* serve to hold the rings in place when there is no steam pressure upon them. With steam pressure in the chamber *H,* the rings are held tightly against the rod.

Each packing ring is in two parts, making four segments in all, which are interlocked when in place. Fig. 13 shows a transverse section along the plane in which the two rings meet. *A* and *B* are the two parts of one ring and *C* and *D* the babbitt projections from the other ring. The two parts *A* and *B* are held together by a band spring, *C,* which in Fig. 12 is denoted by *G.* The pins *E, E,* prevent the shifting of the steel spring around on the ring.

In Fig. 14 is shown a single segment, from which its form and construction is apparent. The lug *A* is merely an extension of the babbitt lining *B* of the ring. The distance this lug projects is just equal to the width of a ring. The projection has two flat surfaces, meeting at right angles, and one curved surface whose curvature is that of the rod. When the segments are put together this lug fits beneath the two ends of the adjacent ring, as shown at *C,* Fig. 13.

These are by no means all of the types of metallic packings. There are many more. However, the various kinds illustrated will

serve to indicate the ends toward which designers have worked to produce a good metallic packing. First, tightness of joint, whether under steam pressure or under a vacuum; second, a minimum of friction and wear; third, simplicity and freedom from continual care and adjustment; fourth, applicability to various conditions without change in the design or construction of the engine; fifth, low first cost and reduced cost of maintenance. The packing which combines the greatest number of these desirable features is, doubtless, the one which will be in greatest demand.

FIRE PROTECTION IN TELEPHONE EXCHANGES.

BY H. S. KNOWLTON.

The importance of preventing fire losses is recognized today in practically every branch of modern industry, but it would be difficult to point to any application of electricity on a large scale where continuous service is of greater consequence than in the telephone exchange. Valuable as is the central station in urban and suburban life, and indispensable as is the street railway to both city and rural communities, the telephone is beyond question the greatest time-saving device of modern times, and therefore the one thing above others which the business world is least able to spare, even for a single hour.

At first blush, the telephone exchange of today might seem to be subject to but a slight fire hazard. There is no generation of power on an enormous scale; the building is frequently heated by either a hot-air furnace of usual design or by a low-pressure steam boiler; the central office equipment presents no high-voltage problems in itself, and the wire plant is reasonably well protected from foreign currents by the lightning arresters and heat coils installed on the main distributing frame or in cable boxes outside the office. A careful examination of many exchanges, however, will show even today practices which deserve criticism, despite the lessons of the great conflagrations of 1904 in the United States and Canada. A great deal has been written about fire risks during the past year, and much has been done to reduce hazards in electrical work no less than in other spheres of activity; but as long as the maximum of precaution is not observed, so long is the subject of vital importance.

The fire risk in the modern telephone exchange depends upon the external hazard, the internal conditions and the precautionary measures adopted. It is often difficult to so locate the building that it will be free from dangerous exposure to adjacent or adjoining structures. If a ramshackle barn, shed, shop or tenement occupies abutting property, it is at times possible to purchase such realty at a fair price and entirely renovate it or else sell the site again for fire-proof buildings only. When this cannot well be done, recourse should be had to seamless fire shutters of wood covered with tinned iron and having locked joints, at all exposed windows. In case such windows cannot be equipped with shutters—and often for aesthetic reasons this is the case—these windows should be glazed with wired glass set in metal-covered frame and sashes. On front windows, as in executive offices, etc., the risk is seldom as great as on the sides and rear, so that in cases where clear glass is used the metallic frames and sashes should be supplemented by tightly-fitting asbestos roller curtains. In all cases it should be possible to close shutters from outside as well as from within.

Empty boxes and packing material should not be allowed to accumulate on the roof, and rubbish of any kind has no business in the yard unless it is stored in covered waste cans of metal construction. In the telephone business there is a constant tendency for rubbish to accumulate on account of the thousands of individual pieces of equipment used in central office work. These all come from the factories carefully packed, and the disposal of the packing cases and boxes is a matter of more than passing importance. Ashes have no rightful place in wooden barrels, and in the matter of these general hazards, the problem does not differ widely from that met in factory and power plant work. Incidentally, it is worth while to provide every telephone office surrounded by a yard with a coil of hose and movable hand reel capable of covering the premises, locating faucets on each side of the building about two feet from the ground. On the roof a hose and water supply is also extremely useful in case sparks and burning brands are blown upon it from external fires. The point of greatest danger from external hazards is usually in the operating room behind the switchboard. Windows are generally cut in the wall here in order to provide ample light for inspection and repair work in connection with the complex cable and cord circuits, relays, lamp and jack banks, etc., which make up the operating features of a multiple board. Wired glass and metal sashes can almost always be used in such windows with perfect satisfaction.

Into modern exchanges 500-volt central station power circuits are frequently carried to supply motor-generators for storage-battery charging or elevator service. The usual precautions recommended by the National Board of Fire Underwriters are imperative in such cases, particular care being taken to prevent contact of the circuits with wood or metal work, pipes and other circuits. Gasoline engines are also widely employed in telephone exchanges for driving generators for battery charging work. The use and storage of gasoline is a matter of dangerous risk on telephone property for the reason that the gasoline vapor collects in low places where it is liable to explode when mixed with a certain percentage of air—about one volume of gasoline vapor to ten volumes of air—but if the apparatus is properly installed and maintained danger may be entirely avoided. An automatic valve which will cut off the supply of gas in case the engine stops should be fitted to every gas engine used in a telephone office, and the exhaust piping of either a gas or gasoline engine should be carried up to the roof with the greatest possible directness. It is bad practice to discharge such pipes into chimneys, the better plan being to either run them upward to the roof through special fire-brick flues in the walls or else to extend them outside the building proper. Separating thimbles should always be provided where such piping passes through woodwork. The storage of gasoline should be effected in a tank located well away from the building out-of-doors, say 30 or 40 feet from the walls. Fire protection engineers are unanimous in the opinion that gasoline should never be stored indoors in any quantity. When it is necessary to keep a gallon or two inside temporarily it should be held in a strong can with a self-closing cover, preferably painted with red stripes to call attention to its dangerous characteristics.

In this connection the use of soldering iron heaters operated by either gas or electricity deserves mention. The important point is to provide both irons and heaters with a non-combustible support. It is not uncommon to see heaters in operation on wooden shelves, so hot that the hand can scarcely bear continuous touch, and in other cases gasoline torches are set on operating-room floors in the most promiscuous fashion. Swinging gas fixtures and the careless use of flexible lamp cord around wood and metal work are responsible for fires in many cases. Paper should never be wrapped around incandescent lamp bulbs, particularly in the vicinity of switchboards. Wire guards ought to be used on all portable lamps, and half shades of metal in cases where screening is necessary. Insulated keyless sockets are also preferable. Gasoline torches and electric heaters ought never to be left burning or connected to the supply circuit during the lunch hour, as the deserted condition of work rooms at such time of day offers especially favorable chances for the spread of incipient fires.

In a properly designed and operated telephone exchange there should be slight occasion for the use of matches. An alternative means of lighting the building is always important in case the regular service fails. Many offices are equipped with gas jets for emergency use, while others rely on candle lanterns. The careless use of matches is one of the most common facts of life, and in the telephone exchange precisely the same caution needs observance as makes for safety elsewhere. This means the storage of all matches in metal boxes with self-closing covers, instead of placing bunches on wooden shelves, on stray brackets, etc. Incidentally, the careless use of tobacco in work rooms, store rooms and closets deserves severe condemnation, and the employment of sawdust spittoons and combustible waste baskets has no place in the telephone office.

A liberal supply of fire extinguishers, fire pails, sand buckets with scoops, dogskin gloves, asbestos or woolen blankets and waterproof covers should form a part of every exchange's equipment. The use of water about the switchboard is poor policy, and here compressed carbonic acid gas extinguishers are specially advantageous. Dry powder extinguishers or bellows filled with

such powder are often desirable, and for general use in hallways, closets and offices this type finds much favor. Sand buckets may be proportioned through the plant as follows: One bucket in the terminal room or at the main distributing frame, and in the operating room one near the head of the board and one for each five sections. Corrosive solution ought never to be used about switchboards and desks, distributing frames, etc., except in extremes to put out the fire when all other means are unavailable. Asbestos blankets are preferably about 36 inches square, and good practice provides one for at least every ten sections of the switchboard. They are particularly useful in putting out fires caused by high-tension crosses. Waterproof covers for switchboards and machinery are desirable in the event of the operating or the power room being flooded by the fire department. To avoid damage by water, switchboard cables should be run at least four inches above the floor, and whenever such cables pass through the floor the opening should be lined with a galvanized iron guard, preferably projecting above the opening high enough to prevent water from flowing through. It is also important to provide such openings with closely fitting covers so that drafts of air cannot circulate between floors.

The proper maintenance of fire-protection apparatus is a matter of the utmost importance. Good practice now provides that water pails be refilled at least once a week, that weekly inspections by a responsible employee be made of the entire equipment, and that extinguishers be discharged and refilled certainly every twelve months. Valves and hose should be tested at least once a week, and fireproof shutters and doors ought also to be tried with equal frequency to make sure that they are in good condition. Thermostat alarms in out-of-the-way corners of the plant are desirable, and between the cord shelf and the multiple jacks on the switchboard asbestos fireproof barriers can be installed with profit. The nearest fire engine house should be equipped with a direct telephone line from the exchange.

The safety of the operating force is of paramount importance, and ample facilities in the way of fire-escapes should be installed. On account of the strict discipline necessary to insure good service, telephone operators as a class are usually cool-headed and can be managed in times of emergency with more than ordinary confidence. Nevertheless, fire drills are worth instituting in offices where the operating room is above the second story, and there is good reason to provide at least two separated exits from such rooms to the street. Fire protection in telephone exchanges is a matter of many small details, but it is not a question of large expense, and there is no excuse whatever for the continued existence of extra hazards in such installations.

Old Engine—An engine, one hundred years old, has been displaced by a steam turbine at Greencroft Mill, Hyde, England. The crank shaft of the engine made 30 r.p.m.; that of the turbine makes 10,500 r.p.m.

ELECTRICITY IN SOUTH AFRICAN MINES.

BY GEORGE E. WALSH.

The use of electric mine pumping apparatus in the South African mines has developed rapidly in the past year, and ever since the close of the Boer war activity in working the old and new mines has progressed steadily. Electricity is gradually displacing steam and compressed air in South African mines for operating hoists, drills, stamps and general mine haulage, but in none of these departments is the change quite so noteworthy as in the pumping line. Attention has been called recently to the durability of the motors used in the Knight's Deep mine prior to the war for pumping purposes, which after being abandoned for over two years in the flooded mine were taken up and put into successful operation again. This incident is of value as indicating the kind of work demanded in many mines of pumping machinery. Unless the pump motors are water-proof and reliable in damp places they cannot prove of great utility. Compressed air displaced steam to a large extent in the chief African mines because of this very quality.

Electric mine pumping is accepted on the Rand as the most serviceable and satisfactory of any system yet tried. Nearly 3,000,000 gallons of water have to be pumped out of the Knight's Deep mine every twenty-four hours, which requires some 12,000 horse-power. At the Robertson shaft three electrically-driven pumps have been in operation for some time, delivering some 400,000 gallons of water a day against a head of 1,250 feet.

At the De Beers consolidated mines at Kimberley, electrical pumps have recently been put in operation. Two of them are of the centrifugal high-pressure type, coupled directly to polyphase motors, each capable of raising 1,000 gallons of water per minute to a total height of 320 feet. The pumps are operated by motors developing 150 horse-power at 730 revolutions per minute. A smaller pump is operated by a 75-h.p. motor, and the water is raised 160 feet at the rate of 1,000 gallons per minute. The pumps are connected with the motors by flexible couplings. The overload capacity of the motors is 100 per cent, and the efficiency of the pumps is 75 per cent at full pressure. The motors are of the enclosed type and practically waterproof and damp-proof. They are so arranged that they can be operated with the least possible fear of damage or injury from weather or careless handling. The pumping can go on night and day when the rest of the power of the mine is shut down. As the air is renewed very slowly in such deep mines the rise in temperature of the motors caused by continuous use is important. In the Kimberley mines the full rise in temperature averages only 18 degrees Centigrade after the motors and pumps have been in operation at full load for many hours.

The experience of mining engineers with electricity in African mines has been so satisfactory that there is little likelihood of further extension of steam or compressed air for operating the pumps there. In nearly all gold and tin mines the amount of water present is so great that the workmen are hampered by it, in nearly all cases the rocks which carry the metals being also "water bearing." On the other hand the immense amount of water needed for the machines used to separate the gold or tin and the dross and gangue makes the presence of a fair amount of water important. The right quantity of water may thus prove of distinct value to miners and engineers have the problem of providing pumps of the right sort to solve before anything else.

The gold mines of South Africa are very deep in many instances, and the amount of water required to be pumped out is enormous and the distance very great. In both the tin and gold mines, the lodes are nearly always at an angle with the horizontal, and the inclination is rather deep. Sometimes the angle leads to such depths that it is impossible to pump the water up to the surface with any degree of success. Several of the shafts have been sunk to 2,000 and even 3,000 feet, and the cost of driving the water up against such a head has been deemed almost too expensive to try. Nevertheless, the presence of gold in paying quantities at these lower depths has stimulated mining engineers to greater effort. Pumping units have been tried on the Rand which force the water up against a head of 2,000 feet and more.

In these experiments electricity has been found the most efficient for a number of reasons. The loss which occurs in steam pipes in deep mines practically excludes steam-operated pumps from use at any depth greater than 1,000 feet. In tests made with steam pipes in mines it was found that steam under a pressure of 45 pounds per square inch through a pipe one inch thick and 7½ inches in diameter lost through condensation 0.183 pound per square foot of surface when the engine was standing, and 0.274 pound when the engine was working. This was equivalent to the loss of 500 pounds of water per hour when the engine was idle and 750 pounds when in operation, in the cases under test.

Further tests made with steam pipes a trifle under 2,000 feet in length, showed a loss of 0.113 and 0.265 pound of water per square feet of surface per hour with the pipes covered. Uncovered pipes showed a loss equivalent to almost one pound of water per superficial foot of pipe exposed. Accepting these tests as representing a fair average of loss, it was assumed by the engineers at the Knight's Deep mine that about 230 pounds of coal per hour would be consumed to make up for the loss of power through condensation in a pipe 2,000 feet long.

On the other hand, the loss of electric power through long circuits underground is almost a negligible quantity. In the German mines of the Harpener Bergbau large electric units have been used which show low cost of operation in deep pits. The depth of one of the shafts where an electric hoist and electric pumps are used is 1,968 feet. The power house is equipped with

a 600-h.p. horizontal compound steam engine direct-connected to three-phase generators delivering current at 2,400 volts with a frequency of 25 cycles per second. This current is used for operating mine hoists and pumps. The latter are far under ground, and the total distance over which the current is transmitted to operate them is 2,460 feet. Double-acting pumps are installed at the bottom of the shaft, and they raise 176 cubic feet of water per minute a distance of 1,476 feet. The motors which operate these pumps run at 65 r.p.m. and operate directly from the 2,400-volt power circuit. The saving obtained from these electric motor-driven pumps is so great that the profits of mining at depths below 1,000 feet have been increased surprisingly.

The added advantages of lighting the shafts and tunnels electrically and of protection from fires and explosions have also tended to increase the preference for electricity in gold mines. In coal mines the danger of fire when the air is full of fine dust and gases has led to the installation of electric units located above ground or with every possible protection when placed in the mines. In most of these cases the frame of the motor and the cases in which the fuses are enclosed are ground securely and the fuses themselves are placed in gas-tight boxes. The slip rings of hoisting motors are also encased in tight boxes. Where the sufficient precaution is taken to prevent the different parts from causing fires or explosions in shafts where the air is liable to carry large quantities of inflammable gases and coal dust, all danger is practically eliminated.

At a recent meeting of the Mining Institute of England, the question of electricity in coal mines was discussed, and as a matter of safety it was decided that pressures of 3,000 volts or more should not be used at all, and the consensus of opinion was that pressures as high as 650 volts should not be used outside the main intake airways or chambers directly supplied from them. Cables carrying high pressures in the mines should be enclosed in armor or iron pipes, and all metal conduits should be connected to earth.

The three-phase system has found more advocates in the mines than the direct current owing to the absence of commutators and the general simplicity of the three-phase machinery. Nearly every kind of mining machinery has been adapted for driving by three-phase motors.

SHOP SYSTEM FOR ELECTRICAL CONTRACTORS.

BY LOUIS J. AUERBACHER.

The shop and accounting system of any electrical contracting business very naturally varies according to the amount of business done, so that it is out of the question to give a system which is applicable to all cases. That described herewith is suitable for a concern doing a general contracting and jobbing business and employing from 15 men upwards. The system is simple and accurate, and the forms used are the result of a gradual development. They are designed to avoid the cumbersome detail common in many record forms, and have been evolved with the life of a number of concerns who make a daily use of them.

WIRE, CONDUIT & CO.
ELECTRICAL CONTRACTORS
[illegible]

Job C № 1350

New York, Sept 11 1905

Charge to John Jones

For work at 1450 - 6th Ave.

Order received by B.B

Order acknowledged 9/12 — Work commenced Sept 12 — Foreman Smith

Contract account X — Work completed ____

Contract new 725.00 — Charged ____

L. & M. or R. ____ — Bill ____ — C/f sent customer ____

Description of work

FORM A (*White*).

Actual size, 9 inches wide by 8 inches high.

The orders, or contracts, received are divided into two classes; those in which a contract for a stated price has been made, and those classed as time and material jobs.

As an example, a contract for wiring a house at a price of $1,000 is received. The original order or contract, properly signed, is filed in a special file, which should be kept in a safe. The order is entered, in duplicate, on a blank, Form A. One copy is given to the foreman and the other is kept in the book. The orders are consecutively numbered, and the contract is then known as job No. C1. The price is not put on the copy given to the foreman, as it is not considered good policy to have the prices of contracts generally known, except to the firm.

The foreman is expected to learn the exact nature of the work, either from verbal description or specification. He then makes

a list of the material needed to start the job. This may be done from an analysis of the estimate, or, better still, by an inspection of the building in which the work is to be performed. The foreman then fills out a "material slip" so that the stock clerk can get the materials promptly to the job.

WIRE, CONDUIT & CO.
ELECTRICAL CONTRACTORS
1000 Ohm Street

Job R №. 7994

NEW YORK, Sept. 11 1905

Gentlemen—Please furnish the material and perform the labor for the following work to be done at 670 West 10th St
and charge same to the account of Wm Bradley
Terms ______ ~~Contract~~ New

Description of work *Order received by* ______

Repair broken circuit wire

FORM D (*White*).
Actual size, 7 inches wide by 11 inches high.

Such a slip is shown in Form B. The stock clerk should be prohibited from filling any orders unless the job number is on the requisition as well as the signature of the foreman or other authorized person.

These slips, after being filled, should be carefully filed, so that all slips for one job are together. A good way of doing this is to fasten them into a blank book by pasting the slips on pages corresponding in numbers to the job numbers. In case there are a number of slips for one number, these may be pasted over one another by gumming the edges.

The getting of the proper material promptly on the job is one of the important duties of the stock clerk. He should promptly notify the foreman of any unlooked-for delay, so that workmen are not kept waiting for the necessary material. The cost of errand boys and proper wagon service should not be stinted, as delays in receiving materials promptly cause a considerable leak in the profits. The stock clerk should insist upon getting a proper receipt from the foreman or wireman on the job, for materials delivered. (See Form C.)

Foremen and wiremen should be instructed to measure for special fittings as soon as practicable, so that the material may be on hand when needed. This refers especially to panels, trims, switch plates and all fittings not regularly carried in stock.

Should any extra orders be obtained in a contract job, the order for same should be entered on a separate blank. If the extra is obtained at a stated price, blank Form A is used.

Many extra orders are usually received verbally; they should be acknowledged at once, stating prices and the work to be performed. This will make the settling of the account a simple matter, as any misunderstanding can be adjusted before the work is under way.

For all orders received on which no price has been set the accompanying blanks will be found suitable. In Form D a different letter is used before the number, to distinguish these orders from the stated price jobs. These orders are made in duplicate, a carbon copy remaining in the book. When receiving such an order the customer should be told the price per hour for labor, and, if

A

Anderson B, C 121 L & M 646-732-926
Adams T. B. C 162 L & M 930-1106-1109

FORM G (*Straw*).
Actual size, 5 inches wide by 3 inches high.

practicable, the prices per unit for material. If the order was given verbally, the customer should be asked to sign an order similar to Form E.

The wireman should fill out the reverse side of the slip (see D1), and when finished with the work have it signed by the customer or his representative. This is a check for both the contractor and his customer, and prevents disputes when the bill is received. Time and material jobs, unless properly handled, often lead to disputes. To avoid these, the customer should be advised as to the progress of the work and the approximate cost of the same. If any difficulties arise which will increase the price, he should be informed. The contractor should insist upon the customer or

	Mdse.	Labor.

FORM H (*White*).
Actual size, 8 inches wide by 12 inches high.

When surplus material is returned from a job a proper return slip is filled out. (See Form F.) This slip should be of a different color than the stock requisition slips, to prevent errors in entering.

All orders, either contract (C) or labor and material (L and M) are indexed, to prevent the omissions of any slips when entering the charge. The bill clerk or bookkeeper should check them off as billed, or start a tracer for any missing orders before billing. (See Form G for index system.) When making out bills the slip numbers should be placed on them. This makes it easy to look up slips should there be any disputes.

In keeping the cost of a job a loose leaf book is best. The page should be numbered to correspond to the job number. The customer's name as well as details of the job should be on this sheet. In an iron pipe job the number of outlets, switches, receptacles and panels should be given. These details should be copied from the specifications by the clerk who keeps the stock book and serve as a check on the material. If the original contract called for 24 switches and the sheet shows that 28 went out, a reason should be given for sending out the four extra switches. The form also serves to keep cost records per outlet, etc., etc.

The cost books should have the material entered up daily and the labor weekly; the cost is running unreasonably high, a conference should be had with the foreman in order to ascertain the reasons and apply the proper remedies.

The stock room should have a complete line of standard material, especially little fittings which are often required in a rush. Much money is also saved by buying goods in so-called standard packages. Where goods are ordered from supply houses or manufacturers a regular order blank should be used, and this should be the only means of obtaining goods. To be valid the orders should be signed by one or two authorized persons. The job number should be on the order as well as the other information. (See Form I for order bank.)

Where materials are ordered to be shipped direct, the foreman or wireman on the job should fill out a slip (Form J) when he receives such material. This enables the stock clerk to check the bill for material as to quantity and quality.

All supplies received should be entered in a receiving book so that the bills can be checked. (See Form K for receiving

usually very lax in bringing back unused material to the shop. A system for keeping track of ladders and special tools supplied to wiremen is necessary. A number of hooks are mounted on a board, and these are numbered to correspond to numbers on ladders and tools. When a ladder is sent out a tag is filled out containing the job number, name of workman in charge and date. This is placed on the hook corre-

sponding to the ladder number, and is left there until the ladder is returned or shifted to another job. A similar system can be applied to pipe cutting and other special tools.

Keeping employees' time records and checking the same is naturally one of the vital parts of any shop system. The names and addresses of all employees, together with their rating, such as apprentices, helpers and journeymen, should be noted in a book for that purpose. If the employee is discharged or laid off, a note should be made, together with the reason. If he is found to be proficient in a certain line, that fact should also be recorded. Men are often laid off during slack times, and should the firm require a good man on iron pipe work, a search of the records will enable a postal to be sent to a number of the right kind of men.

A daily record of the disposition of the men should be kept so that the time sheets can be checked, and the numbers of the jobs they are on should be credited to them. If new L and M job slips are issued and assigned to a man, they should be charged to him.

Time sheets should show the employee's name, classification, rate of wages and daily record, and also expenses. (See Form L for time sheet.) An employee should fill out his own time sheet and have the foreman check same. It should then be checked by the general superintendent or some one else in authority, who would use the daily time book for that purpose. The time sheets should be figured and entered in the time book by the bookkeeper. The time charged against the various jobs should then be entered on the cost sheets. All time charged on L and M order tickets should be compared with those tickets, as a check. This will show if it corresponds to the signed acknowledgment of the customer. (See Form D1.)

The cost sheet of a finished job should be compared with the original analysis of the estimate. This will enable the estimating clerk to check up his work, and if a discrepancy occurs, say in labor, it should be brought to the attention of the proper party and an investigation made as to whether the job was poorly handled or the estimate was wrong. The cost sheet will serve as a check both ways.

If a contractor makes his own special fittings and fixtures, and does his own machine and carpenter work, a shop order system is necessary. All material or work ordered from the shop should be ordered on a special blank. (See Form M.)

FORM L (*White*).

Actual size, 11 inches wide by 8½ inches high.

These blanks should be in duplicate and consecutively numbered.

On the reverse side (Form M1) the foreman notes the time, the materials used, and the cost. This will enable a proper record to be kept in the cost book, and also serve for fixing the price to the customer. Where a large number of L and M sheets are made out, it is well to keep a record of them on a separate sheet. (See Form O.) When the bill is sent out the amount is filled in on the sheet by the bill clerk, which shows that the final entry has been made.

A good card index system for following up contract work is essential. Cards printed as per Form P are used. Space is provided for noting whether the service application to the local illuminating company has been made, if the application for inspection to the local inspection bureaus has been made, and also when the certificates were sent to the electric light company, and when returned. On the reverse side is entered the job number of all slips on the job, also the amount of same, and this is totaled when the job is finished. These cards are kept in three drawers of a card file and shifted as the job progresses. One drawer is labeled "Jobs Started," another "Jobs Completed," and the third, "Bills Sent and Paid." These cards also serve as reference for the head of the establishment, and for the collection department.

The departments of a contracting busi-

ness are divided into the executive, accounting, operating and sales. The executive department naturally directs the heads

cost book. The head of the operating department is the superintendent. He should pass on all estimates and approve all the layouts of different jobs. He is responsible for the profitable and workmanlike results expected, and in large concerns has estimate clerks and draughtsmen to assist him. The foremen report to him, and he should be able to design any special fitting or device found necessary.

Foremen are assigned to districts and should visit all jobs at least once a day, for in no other way can discipline and a fair day's work be obtained from the working force. The foreman should see that proper tools, ladders and material are on the job, and should instruct the workmen how to run their circuits as well as locate outlets, switches, bells, etc., etc. He should order any special panels or other devices in time, so as not to delay the work. If violations are filed oftener than reasonable, he should be discharged for carelessness.

The stock clerk has charge of the stock and the shipping of materials to the jobs. In this department none other than an active, energetic and accurate man should be tolerated, as a careless stock clerk may cost the concern hundreds of dollars. To get the right material to the job quickly, and to order the special devices necessary, requires good judgment and experience. A big leak is possible in this department, and the stock clerk's records should be checked carefully.

The following time and material were used on the enclosed order.

______ Foreman of Shop.

Total Cost______$

FORM MI (*Pearl*).
Actual size, 6 inches wide by 6 inches high.

The stock clerk should be held accountable for all material and tools, and an inventory should be taken at least twice a year. He should keep two files for the material slips; one for those filled and another for those unfilled. He should advise the foreman if he anticipates any undue delays in receiving material ordered, so that the foreman can govern himself accordingly. If the stock clerk finds that he cannot entirely fill an order for material, he should make out a due ticket similar to Form B, except that it should be of a different color and read on top "Due Ticket." The foreman can then see at a glance how many due slips there are and get after the stock clerk.

The sales department should have as many solicitors as are found profitable. In many cases the foremen are used as salesmen, and if they have the time it is a good plan. Workmen on the job, especially in private houses, make the best salesmen for extras, and if properly instructed will bring in considerable business. One salesman should look up the real estate transfers and removals. He should call on parties who have purchased houses and solicit business. If that branch of the work is sufficient to keep a man busy, another should solicit business among architects, builders and decorators. A proper card "follow up" system, of which there are many on the market, should be used.

All requests for estimates should be turned over to the salesman who usually calls on that customer, if it be an old account; if not, the salesmen should be consulted to see if they know the party or any one having influence in that direction.

At certain times in the year removals are frequent and placards in the windows of stores announce the intended removal to other quarters. A call on such parties frequently results in orders.

The system described can be broadened or cut down to meet requirements. The owner may be his own superintendent and foreman, as well as do his own estimating and draughting. The bookkeeper can do all the bookkeeping and collecting, etc., etc.

A system of this kind will be found very valuable and is inexpensive. It must be kept up to be of value, as partial records of costs and other details are worse than none. Oftentimes in an endeavor to improve matters, too theoretical a view is taken leading to the employment of elaborate and complicated forms. Records should be as few and simple as possible. A good system

is additionally valuable, as it does not make a "one-man business" out of a concern. A new man, by consulting the records, should be able to grasp his duties, as well as the swing of the business, at once.

AN INTERESTING GAS ENGINE PLANT.

BY K. S. HOWARD.

Although small gas engines have attained wide usefulness in isolated plant service during the past few years, the range of adaptability which such installations at times illustrate is worth emphasizing again. In certain establishments economy of space is of such far-reaching importance that no boiler plant can be built on the premises, and in all commercial installations it is desirable that the cost of power be reduced as much as possible without hampering the service.

A case in point is the plant of "Green, the Druggist," in Worcester, Mass. The use of electricity in drug stores has increased greatly of late, and the possibilities of the incandescent lamp in the way of effective illumination for advertising and display purposes can no longer be ignored by progressive houses. The advent of the electric sign and the small motor has introduced new methods into many branches of retail business. Most city drug stores are hard pressed for space, and the compactness and cleanliness of electrical equipment long since demonstrated the superiority of electric power in situations where the direct use of gas, kerosene oil or acetylene would be unfavorable to the production of the best quality of work.

The Green plant is located in the basement of the store of that name at Main and Pleasant Streets, Worcester. The corner occupied by the establishment is one of the busiest in the city, and at this point rents are close to the maximum. A large number of 16-c.p. incandescent lamps are used in the store proper, around the soda fountain and counters, in ceiling clusters and in the windows, while outside the building illuminated signs equipped with 4-c.p. lamps are in nightly service. Several large fans and enclosed arc lamps are also in use, and in the basement is a 3-h.p. motor which drives an ice crusher and an ice cream freezer by belting and a short line shaft. These machines are used for the soda fountain supply. Current for lighting and small power work is drawn from the plant by several adjoining merchants.

The plant has been in service some 3½ years and is said to have paid for itself in two years. From the æsthetic standpoint, the equipment offers small attractions because of its exceedingly cramped location, which is so unfavorable as to preclude anything satisfactory in the way of a photograph. Squeezed into little more than a basement closet 21 ft. long, 9 ft. wide and 7 ft. high, and surrounded by packing cases and the miscellaneous débris which only drug and grocery stores seem to accumulate below stairs, it looks as though operating efficiency might be out of the question, at first sight. The aspect of things changes, however, as one examines the equipment and notes the character of the service given.

Gas is supplied from the mains of the Worcester Gas Light Company to the plant through a 60-light meter located under the sidewalk, beneath Pleasant Street. From the meter the gas is led to the engine, which is a two-cylinder Nash machine of 30 horsepower, working on the usual four-stroke cycle, and governed by the hit-and-miss explosion method. The engine is of the vertical type, weighs 26.6 pounds per horsepower, or 8000 pounds total, and occupies a floor space of 72 x 74 inches, with bed plate. It has two 72-in. fly-wheels, makes 275 r.p.m., and drives by belt from a 36 x 16-in. pulley a 17.5-kw., 4-pole General Electric dynamo, over-compounded from 110 to 115 volts, speed 1175 r.p.m., direct current. The full capacity of the engine is 300 16-c.p. lamps, and its cylinders are cooled by city water. A two-panel slate switchboard is placed between the engine and its generator and against one of the walls a 15-point end cell switch for use with the storage battery.

The storage battery is located in a basement room and passageway adjoining the engine room and it consists of 72 of the Electric Storage Battery Company's E-11 cells, in E-11 glass jars, capable of discharging at the rate of 25 amperes on the 8-hour basis, or 100 amperes on the 1-hour rate. These cells are arranged in single rows and in three tiers along the walls of the room and the sides of a narrow passageway through which persons frequently walk, and the jars are protected by doors in front of the wooden skeleton frame which supports them. The cell connections are of the single strap lead type, bolted, and the jars are insulated from the frame in glass trays filled with sand, which is an effective, if unusual method of preventing leaks of current. Ventilation is provided for by grated openings in the sidewalk above. One of the switchboard panels is given up to the battery; it contains a central zero Weston 100-ammeter, an underload circuit-breaker and rheostat for equalizing the charging on both sides of the battery, pressure wire connections being made on the adjoining panel to enable each half of the battery to be plugged into the voltmeter. The battery is charged in two sections, which are placed in parallel by switches on the board. The other panel contains various feeder switches, a voltmeter and an ammeter, field rheostat and a double-throw, double-pole switch for throwing the plant upon the mains of the Worcester Electric Light Company in time of emergency.

The engine and dynamo are usually operated from 2 p. m. to 1 a. m., the battery carrying the load at other hours. The battery is charged from 2 to 5 p. m.; it then is used to help out the engine and generator in the evening peak load, which lasts until 11 p. m., and another hour of charging follows from midnight until 1 a. m. The schedule for cutting in lights is: Two inside arcs, 4 p. m.; fountain lights, 5 p. m.; clusters of incandescents and two outside arcs, 6 p. m.; windows and signs, 7 p. m. Lights are cut out as follows: Clusters and electric sign, 11 p. m.; fountain, midnight; all other lights, 1 a. m., except 6 lights in the store, 1 in the cellar, 1 in the cellar stairway and 1 on the second floor, which burn all night.

Very little attention is required by the equipment beyond reasonably frequent inspection to see if everything is working properly. It is estimated that the cost of power per kilowatt-hour at the switchboard is about 3 cents. That the equipment has stood the regular service of over three years to the satisfaction of its owners is a point of interest concerning its economy and reliability, housed as it is in anything but attractive quarters. The wisdom of the emergency connection with the local central station's circuits is beyond question, although little resort to such current is reported. The plant was installed by Plummer, Ham & Richardson, of Worcester, and on the score of compactness and low power cost it is of considerable interest. Figures of first cost are not at hand, but a reasonable estimate is 4 cents per kw-hour to cover fixed charges and operating expenses, based upon gas at $1 per thousand cubic feet. The sale of current to adjoining premises is also a help in the net cost of operation.

Abstracts from Foreign Contemporaries

Arc Lamp Carbon Ends.—L. Bernard describes in a recent issue of the *Elektrotechnische Zeitschrift* an economical method of using up arc lamp carbon ends. This consists in cementing several ends together so as to form a single carbon. The cementing operation is performed by cutting the ends of the pieces so as to make them fit together and then covering the ends with a paste made of water glass and powdered carbon. The pieces are finally pressed lightly together. Made-up carbons of this kind were found satisfactory in every way. They could be used on either alternating or direct-current circuits and burned just as well as new carbons, even at the joints. The resistance of the made-up carbons is slightly higher than the others, while as regards mechanical strength the made-up carbons when subjected to uniform stress, were found more liable to break between joints than at them.

Electrically-Driven Fire Engines.—It is announced in the *Zeitschrift für Elektrotechnik* that two fire engines and a car for carrying accessory appliances, all electrically-driven, have recently been put into service by the Vienna fire brigade. The accumulators, which, is is said, are sufficient to propel the car for some 28 miles at a speed of 12½ miles per hour, are placed in a compartment in front of the driver's seat over the front wheels. India rubber

tires, 125 mm. (49 in.) thick, are fitted to the wheels, which are 850 mm. (2 ft. 9½ in.) in diameter. Each of the front wheels is provided with a 35-h.p. Lohner-Porsche hub motor. The controller provides for the following speeds: 5.6, 6.8, 12.5, 17.4 and 22.4 miles per hour.

Direct-Current Power Transmission at 57000 Volts.—The *Bulletin de l'Institut Electrotechnique Montefiore* contains the following details of a remarkable high-tension direct-current transmission scheme at present under construction. The transmission is between Montiers, in Savoy, and the town of Lyons, and is over a distance of 110 miles—the greatest yet undertaken in Europe. The power to be transmitted is 6500 horse-power, and it is to be generated at 57,000 volts. This will be obtained by connecting four groups of generators in series, each group being directly driven through a flexible coupling by a turbine of 1570 horse-power. Four generators, giving 3560 volts each, form a group. The receiving station at Lyons will contain six groups of motors coupled to railway generators. Each group will consist of two motors, each taking 73 amperes at 3840 volts. In this installation the earth is employed to limit the static voltage of the line, but it does not actually form one of the conductors, except in case of accidental damage, in which case it acts as a reserve line. In this way the cost of the line is practically the same as when the earth is used as the return, while certain useful advantages are obtained. Thus the stray currents are, normally, entirely suppressed, and, in case of breakdown, are reduced by half, while another important advantage is the fact that the earth is always available as a reserve line in case one of the conductors fails. It is expected that this installation will be at work in less than a year.

The Thury Automatic Regulator.—Some interesting particulars regarding the Thury automatic regulator are given in the London *Electrician.*. This device may be arranged to regulate all kinds of quantities, such as speed, pressure, current, etc., but is primarily intended to keep the voltage of electric generators constant by regulating the field resistance. In order to combine rapidity and reliability of action with sensitiveness, the field rheostat is not actuated directly by the fluctuations in voltage; but is operated by a small electric power motor of about 1/20 horse-power, the regulating mechanism being merely brought into play or stopped by the fluctuations of voltage. Fig. 1 is a diagrammatic sketch of the voltage regulator for alternating-current systems, being practically identical with that used in direct-current installations. H is a toothed wheel keyed to the shaft, *L*, which carries the switch arm of the rheostat. *D* is a casting which is rocked to and fro about the shaft, *L*, by the motor referred to. The pawls, *I* and *I'*, are attached to *D* in the manner shown, but are held off the toothed wheel by the spring-actuated levers, *K* and *K'*. Each of these two levers carries a projection at its upper end; the projection on *K* passes normally above the blade, *C*, while that on *K'* rocks to and fro underneath this blade. Consequently, when the blade, *C*, is lowered or raised, it will strike against *K'* or *K*, respectively, thus permitting pawls, *I'* or *I*, to drop into the teeth of the wheel, *H*. The latter is now rotated in the one or the other direction—thus cutting in or cutting out field resistance—until the blade, *C*, regains its horizontal position, when it no longer strikes against *K* or *K'*. Pawls, *I* and *I'*, are then drawn by spring-action out of con-

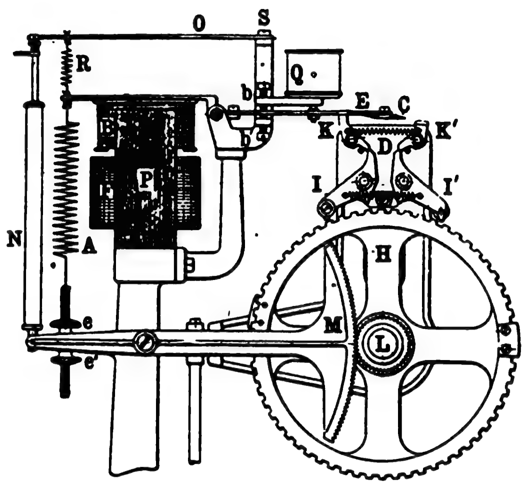

FIG. 1.—THURY AUTOMATIC REGULATOR.

tact with the teeth of the wheel, *H*. Referring to Fig. 1, the electromagnetic mechanism for controlling the position of the blade, *C*, is as follows: *P* is one of the limbs of the laminations which constitute part of the magnetic circut through which a flux is maintained by the coil, *F*. A very light coil, *B*, connected across the bus-bars whose voltage is to be controlled, is free to move up or down above *F*, the movement being limited by adjustable stops, *b* and *b'*. When the voltage of the supply is normal, the current through *B* is such that the lever, *E*, carrying the blade, *C*, is in a horizontal position and nothing happens. But when the supply voltage is higher or lower than the normal, then a correspondingly larger or smaller current flows through the shunt coil, *B*, which rises or falls in consequence and causes the blade, *C*, to move into the way of the oscillating levers, *K* and *K'*, thus actuating the rheostat as previously explained. The coil, *B*, moves against the tension and compression of the two springs, *A* and *R*, the latter being, in its turn, attached to the free end of a flat spring, *O*, fixed at *S*. The free end of *O* is also in connection, through the intervention of a dash pot, *N*, with the pivoted lever, *M*, which takes up a position in accordance with the position of the switch arm by means of the gearing shown. This arrangement, as may be easily understood by reference to Fig. 1, tends to steady the movement of coil, *B*, and to bring it back speedily to its horizontal position after having been deflected. In order to prevent vibrations of the blade, *C*, in regulators for alternating current or where the regulation is required to be unusually sensitive, a dash-pot, *Q*, is also provided. Standard regulators are dimensioned in such a manner that the toothed wheel, *H*, makes one revolution in 30 seconds. If thus the contacts of the rheostat are distributed over two-thirds of the periphery, the regulation between the extremes will occupy but 20 seconds. Of course, a more rapid regulation may be obtained if desirable.

Automatic Clutch and Contact for Arc Lamps.—*The Electrician*, of London, describes the Acton-Worsley automatic clutch and contact for arc lamps, which is a device designed for the easy manipulation of arc lamps suspended from brackets or lofty ceilings, so that by means of a winch and suspension cord they may be lowered to the ground to be trimmed and hauled up again into position without an unsightly festoon of cable. The gear is made to support a weight of over 1 cwt., and is so arranged that when hauled up into position the whole weight of the lamp suspended from the gear is taken off the cord and supported by hooks. There are two parts—the upper part, with a hooded dome, and the lower part, on to which the lamp or other article is attached. All the movable parts are attached to this lower half, so that if anything should go out of gear at any time, it can be lowered for attention at ground level. The device for hooking is very simple, consisting of two large hooks which, by gravity, come into contact with

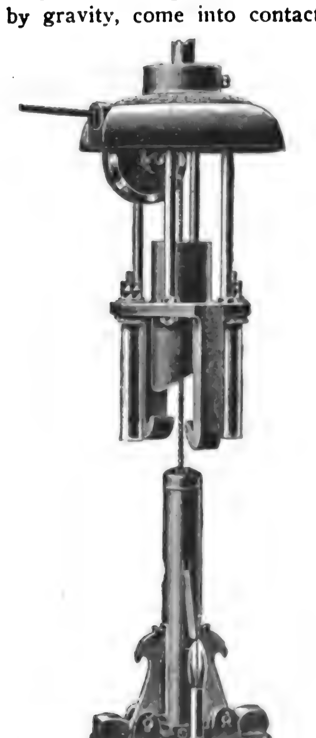

FIG. 2.—ARC LAMP CLUTCH.

two other hooks hanging from the top parts and a small catch-piece which is loosely fixed midway between the two movable hooks. This catch-piece only comes into play when the lower part of the contact gear is hauled up into position. When it is necessary to lower the gear, a slight turn of the winch in the direction of hauling up is made, when the hooks disengage, and the lamp can be lowered to the ground.

The contacts are large, of the plug type, and self-cleaning. A neat cylinder effectively protects the gear from the weather. There are no springs or delicate parts to get out of order.

Electric Transmission of Parcels.—A recent issue of *L'Industrie Electrique* contains a description of an electrically-operated plant for the transmission of parcels and mail matter at high speeds which is now being experimented with by the Société des Chemins de Fer Electro-Postaux. The runs have been made on a circular track of 500 metres (1640 ft.) radius. The car used is 28.8 ft. long by 3½ ft. wide, and weighs 6¾ tons. It has provision for carrying ½ ton of parcels, so long as these do not occupy a space of more than 70 cubic feet. The speed aimed at is 156 miles an hour, and this has been readily attained on trial. The car runs upon a single rail, but is guided by guide-wheels bearing on opposite sides of a special guide-rail. There are two driving-wheels driven by belting from three-phase motors taking current at 1000 volts and at a frequency of 40 cycles per second. It has been found that the speed of 156 miles an hour was attained in five minutes from starting, and on the current being cut off the vehicle came to rest again after the same lapse of time. The retardation on cutting off the current can, however, be greatly increased by means of wind resistances, which are folded down flat on the car when it is running, but are opened out automatically when a certain string is cut by a fixed knife interposed in the path of the car. Forced lubrication is adopted for the principal bearings, which are fed from an oil-pump coupled to a direct-current motor driven by a small battery of accumulators mounted on the car. No details as to the current consumption of the main motors are given.

Some Recent Electrical Patents

Discount Meter.—The increasing application of the principle of a sliding scale of meter rates graded according to the total consumption by a customer of a central station, has led to the development of several forms of meters intended to take care of the sliding scale feature automatically. One of the latest ideas of this general class is illustrated diagrammatically by Figs. 1 and 2 herewith, and has been patented by Mr. Thomas Duncan, of Chicago, Ill. The inventor's method consists broadly of varying the speed of the meter by means of an automatic regulator which varies the resistance of the shunt circuit of the meter and thereby varies its speed when the load exceeds a certain value. Fig. 1 shows one method of doing this, in which sections of a resistance coil, 17, are cut out and into circuit automatically by a solenoid, 19, the plunger of which carries a finger which engages with flexible terminals, 18, connected to the resistance. When the maximum predetermined load is on, the plunger is held down in the position shown, and all of the resistance is inserted in the shunt circuit of the meter, giving its minimum rate of speed per unit of energy. At lighter loads the solenoid plunger is held at higher positions, cutting out more or less of the resistance, 17, and varying the speed of the meter accordingly. The invention also includes an arrangement for giving the consumer a flat discount from his bill by adjusting the speed of the meter. This consists of a second resistance, 13, sections of which are cut in and out of circuit by means of the switch, 14, according to the discount which it is desired to give the customer, the object of this arrangement being presumably to avoid the use of discounts in making out the bills. The supplementary field-winding, 15, is also tapped to a switch, 16, in order that this winding may be strengthened in proportion to the weakening effect when resistance is inserted by means of the switch 14. For example, if no discount is given the switch, 14, rests on the zero contact and the switch, 16, is also set at the zero contact, which gives the meter its normal shunt field. If 10 per cent discount is to be given the switch, 14, is set as shown in the diagram, inserting part of the resistance. To compensate for this the switch, 16, is set on the 10 per cent button, putting in circuit more field winding, which compensates magnetically, but does not counterbalance the resistance inserted by the switch, 14. The meter, therefore, has its normal starting torque with the reduced current flow in the shunt circuit. Fig. 2 illustrates an elaboration of the idea. In this arrangement the automatic grading resistance, 17, is connected in series with the shunt field coils, 19, which act differentially or in opposition to the main field coils, instead of being in series with the armature, the armature being in series with the fixed discount resistance, 13, and another shunt field winding, 15, which is adjustable as in the previous case by means of the switch, 16. The differential winding, 19, is prevented from acting too soon by means of the auxiliary contacts, 20, in series with the winding. These contacts are open, as indicated in the diagram, so long as the load does not exceed the critical point beyond which the sliding discount is to be applied.

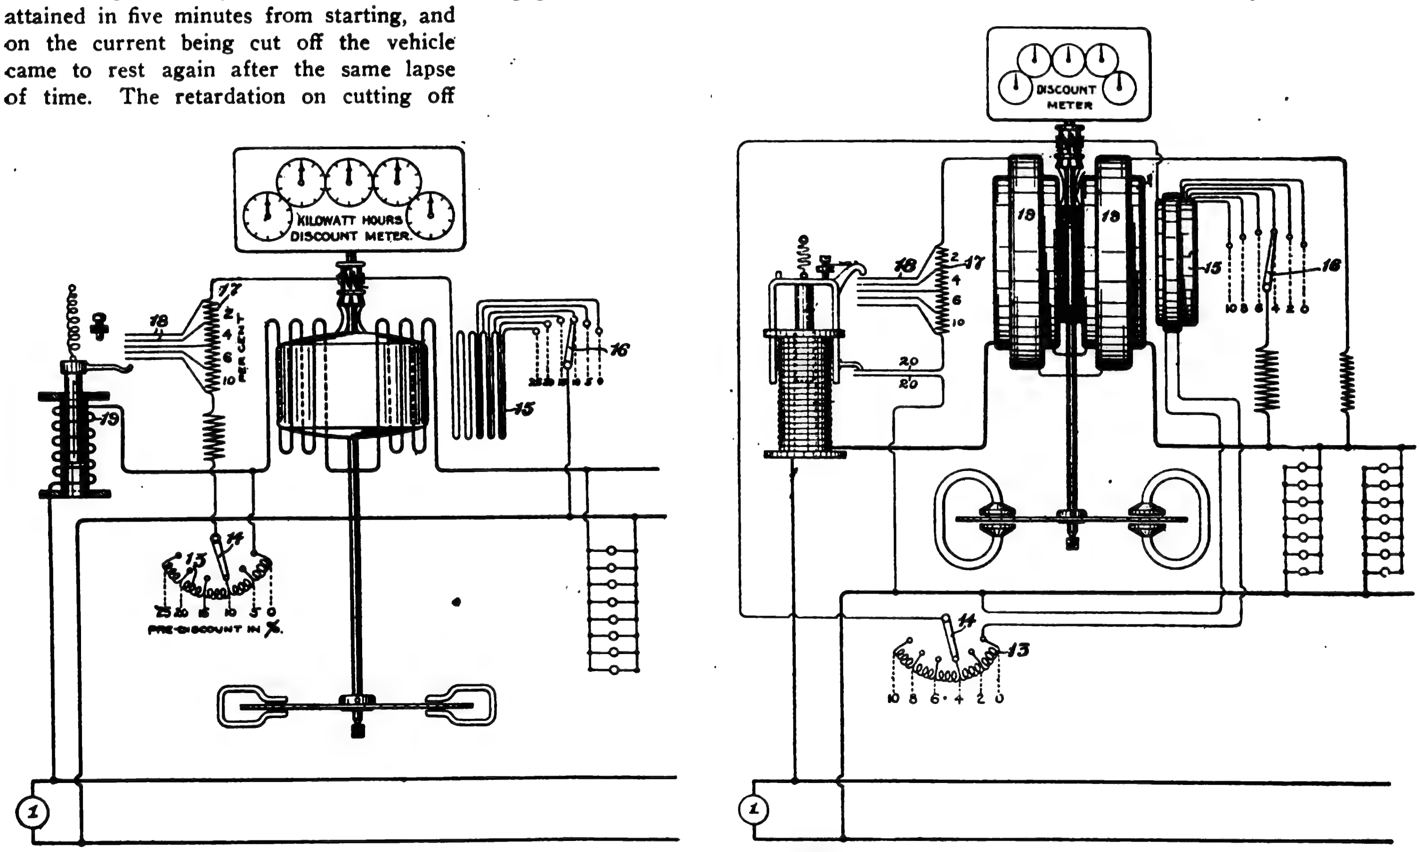

FIG. 1.—DUNCAN DISCOUNT METER.—FIG. 2.

When it does exceed this point, the solenoid closes the contacts, 20, putting the differential winding, 19, in circuit, and further increases in the load cause the solenoid to cut out more and more of the resistance, 17, increasing the demagnetizing action of the field winding, 19. Patents 796,038 and 796,039.

Automatic Regulator for Alternating Current Motors.—It is a fact familiar to those who have followed the development of the repulsion motor that the torque of the machine may be varied by shifting the position of the brushes which short-circuit the armature or rotor winding. Mr. George H. Hill, of Schenectady, N. Y., proposes to utilize this feature of the repulsion motor for the purpose of accelerating its speed automatically, from standstill to full speed, his general arrangement being indicated diagrammatically by Fig. 3. In the diagram the stator winding is represented by *S* and the rotor winding by *R*; the rotor winding is connected to a commutator in the usual way, but for simplicity this is omitted and the brushes, *b*, are shown in direct contact with the winding. These brushes are mounted in a brush-holder ring, *B*, which is adjustable around the axis of the machine and is connected to a similar ring, *e*, by means of a belt, *H*, so that when the ring, *e*, is rotated the brush ring *B* follows its movement. The controlling ring, *e*, carries a coil, *E*, which is arranged in inductive relation to stationary coils, *CC*, the latter being in series with the stator winding. The polarities of the two sets of coils are such that when they are energized the coil *E* tends to turn counter-clockwise, which tendency is opposed by the weight *W* attached to the arm *F*. The drawing shows the equipment as arranged for use on an electric car, so that the ground connections, *GG*, represent one terminal of the supply system; the main terminal of opposite polarity is the wire *T*. When the apparatus is in position of rest, the arm *F* is raised to its horizontal position, where it is held by the latch, *f*; in this position it raises the bridge, *I*, and closes the circuit from the upper ground terminal through the solenoid, *A*, to supply source, *T* (when the switch *s* is closed), which is of the same polarity as the main supply terminal, *T*, but not necessarily of the same voltage. The switch, *s*, being closed under these conditions, current will flow through the solenoid, *A*, and the brush, *I*, to the ground connection which is a common return for both supply sources. The solenoid, *A*, will then raise its plunger and bridge the contacts, 3, 4 and 5, 6. The contacts 3, 4 close the torque circuit to the stator of the machine, and the contacts 5, 6 close the return connection between the solenoid, *A*, and the ground, so as to make the solenoid independent of the bridge, *I*. With the arm, *F*, horizontal the short-circuiting brushes on the rotor commutator are in the position of zero torque and the motor, of course, does not start up. The magnetized current, however, through the stator winding passes through the solenoid, *D*, which releases the latch, *f*, and allows the lever, *F*, to be drawn down by the weight. A shunt current passes from the main terminal, *T*, through the movable coil, *E*, to the ground, and this restricts the downward motion of the arm *F*, and consequently, the circular motion of the brush ring, *B*. When the arm, *F*, falls to a position where the magnetic pull of the coil, *E*, balances the weight, *W*, the brushes will have reached a position where the motor has sufficient torque to start up. As the motor speeds up and the counter e.m.f. in the stator winding increases, the current in the coils, *C*, *C*, will decrease, allowing the weight, *W*, to pull the arm, *F*, still further down, carrying the brushes further around toward the point of maximum torque and increasing the speed of the motor still further. This will continue until the motor is running at full speed and the opposing forces in the regulator are in equilibrium. From the foregoing it will be evident that the regulators operate to produce practically a constant current flow through the stator winding of the motor. The regulator is provided with an auxiliary set of stationary coils, *c*, *c*, which are short-circuited when the plunger of the solenoid, *A*, goes up. When the switch, *s*, is open to shut the motor down the solenoid, *A*, is de-energized, of course, and drops its plunger, opening the two paths of contact. This removes the short-circuit around the auxiliary coils, *c*, *c*, and they then receive current from the main terminal, *T*, and through the bridge piece, *I*, this current passing to ground through the movable coil, *E*. The auxiliary coils and the movable coil, *E*, rotate the ring, *e*, raising the lever, *F*, until it is held in a horizontal position by the latch, *f*. In this position the bridge, *I*, is lifted from its bottom contacts, opening the connection between the main terminal, *T*, and the auxiliary coils, *c*, *c*. Patent 795,392.

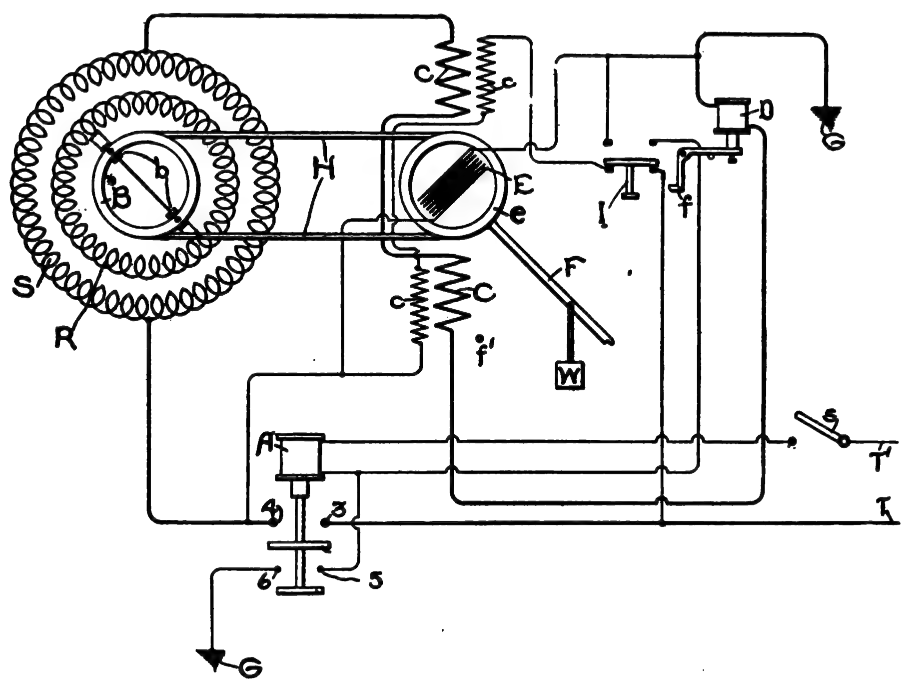

FIG. 3.—AUTOMATIC REGULATOR FOR ALTERNATING-CURRENT MOTORS.

NOTES.

Western Association of Electrical Inspectors.—W. S. Boyd, secretary of the Western Association of Electrical Inspectors, announces that a meeting of this association will be held in rooms 1232-4-6, National Life Building, Chicago, at 10 a. m., October 5 and 6.

Western Society of Engineers—The first session of the meeting of the electrical section of the Western Society of Engineers will be held at the society rooms in the Monadnock Block, Chicago, Friday evening, October 13. J. R. Cravath will read a paper illustrated with numerous lantern slides, on "Do We Need Better Illuminating Engineering?"

Consumption of Electricity in Boston.—Since the advent of the electrical sign in Boston, the amount of electrical current consumed has had such a notable yearly increase that Boston now leads the world in consumption of electric current per capita; that is, in the number of electric light units for each man, woman and child of her population.

Automobile Exhibition in New York City—The Sixth Annual Exhibition of the Automobile Club of America will be held in the Sixty-ninth Regiment Armory, Lexington Avenue, 25th and 26th Streets, New York City, January 13 to 20, 1906. The exhibition will be under the direction of the Exhibition Committee of the Automobile Club of America, 753 Fifth Avenue, New York City.

Ohio Society of Mechanical, Electrical and Steam Engineers.—The annual meeting of the Ohio Society of Mechanical, Electrical and Steam Engineers will be held at Canton, Ohio, November 17 and 18. A number of interesting papers are scheduled for presentation and some proposed changes in the

constitution are to be acted on. Mr. Richard H. Probert, of Akron, is president of the society, and Mr. Corwin J. Miller, of Canton, is secretary.

Fire at Niagara Falls.—Fire started on the night of September 9 in the wire tower of the Niagara Falls Hydraulic Power Company. The fire was upon the wires owned and operated by the Pittsburg Reduction Company. The wires pass through a gate house over one of the waterways and damaged it to some extent, although no damage was done to the power station. The city was left in darkness temporarily, as the power was shut off for the safety of the firemen engaged in extinguishing the burning insulation. Power was delivered to the other customers of the company as soon as the firemen left the building.

Madison Square Garden Electrical Show.—An electrical show will be held at Madison Square Garden, New York City, from December 11 to 23, inclusive. The Director of Exhibits is Dr. George F. Sever, of Columbia University. The office of the Exhibit Committee is at 26 Cortlandt Street, New York City. Among others the following well-known firms have already selected their space and are busy preparing attractive exhibits: National Carbon Company, Harry M. Stevens, Eastern Carbon Works, Joseph Goldfinger, New York Telephone Company, Chicago Pneumatic Tool Company, Electro-Dynamic Company, General Storage Battery Company, G. M. Gest and Ovington Manufacturing Company.

Central Station Advertising.—President Blood, of the National Electric Light Association, has appointed Paul Spencer, of Philadelphia, John F. Gilchrist, of Chicago, and Joseph E. Montague, of Niagara Falls, as a committee to co-operate with the advertising committee of the American Association of Incandescent Lamp Manufacturers in the matter of assisting central stations in the adoption of advertising methods that will result in increased business. It will be remembered that the Lamp Manufacturers' Association made an offer to the National Association at its Denver meeting of $10,000 to be expended for the above purpose, and the offer being accepted this committee has been appointed to complete plans for the work

Welfare Work Medal—The International Exposition of Social Economy, held at Liege, Belgium, has awarded the New York Telephone Company a silver medal in recognition of its welfare work among its employees. The New York Telephone Company has seventeen exchanges in Manhattan and employs about 2,500 operators. In each of the exchanges a suite of rooms has been set aside for the exclusive use of the young women. These suites include locker rooms where each girl may keep her effects under lock and key, a general sitting room supplied with the latest magazines, and a sick room supplied with an emergency medical outfit. In a thoroughly equipped room tea and coffee are served free of charge. The quarters are in charge of a matron who looks after the comforts of the girls.

The Boston Edison Company and the Newspapers.—A vigorous advertising campaign is being carried on in the Boston newspapers by the Edison Electric Illuminating Company of that city. The amount of space taken daily is not large, but the advertisements are placed in unusually conspicuous places and are exceptionally well worded, as the following sample taken from the first page of the Boston *Evening Transcript*, next to the News Summary, shows:

ELECTRICITY

costs you nothing when the current is not turned on. When you want it for power you turn it on and—there you are. You use what you need; you pay for what you use. With steam, cost goes on as long as there 's fire — and after, for there 'll be the ashes to dispose of. And those coal bills!

Have you learned to be power-wise? It will cost you nothing to learn fully. Write, or telephone, our Contract Agent. If you prefer, call to see him.

The Edison Electric Illuminating Company of Boston, 3 Head Place.
(**1)

Central station men are gradually coming to realize that in order to increase their productive output to the utmost, active measures must be taken to enlist the interest of the public in the question of electrical supply. The Boston Edison Company also places signs upon new buildings which it is to supply with current, following the custom of heating and other contractors in such work, in addition to its newspaper and exhibition room activities.

Electrical Exhibition in Chicago.—A company has recently been organized in Chicago to hold an electrical exposition in which electrical machinery, appliances and apparatus in all branches of the industry will be shown. The exhibition will be held in the Chicago Coliseum January 15 to 27, 1906. It will be for the information and instruction of the general public in the various uses to which electricity is applied, and will also interest the electrical fraternity. The name of the company is the Electrical Trades Exposition Company, and includes as stockholders seventy-five of the leading electrical men of Chicago. The officers are as follows: Samuel Insull, president; E. B. Ellicott, Charles E. Gregory and E. B. Overshine, vice-presidents; John J. Abbott, treasurer; Stewart J. Spaulding, secretary; Thomas R. Mercein, general manager. The directors are: Samuel Insull, Edward B. Ellicott, T. P. Gaylord, James Wolff, H. B. McMeal, C. E. Mitchell, Homer E. Niesz, E. B. Overshine, G. H. Atkin, Stewart Spaulding, Charles E. Gregory, G. E. Kohler and G. B. Foster.

Central Station Statistics.—The Census Bureau has just published a report on central electric light and power stations for the year ending June 30, 1902, prepared under the supervision of W. M. Steuart, chief statistician for manufactures. It is the third of a series of reports on the operation and utilization of electric current, and in addition to the text, which was prepared by T. C. Martin, New York City, expert special agent, there are elaborate tables and an interesting series of illustrations. The chapters of text discuss respectively the scope and method of the investigation, financial operations, employees, salaries, physical equipment, output of stations, franchises, and the history and development of electric lighting. The statistics do not include isolated electric light and power plants. For convenience, the various electric stations have been divided into two grand classes—those operated by individuals and corporations and those operated under municipal control. Each of these classes is subdivided into those doing a purely electrical business and those operated in connection with other industries. Further subdivisions have been made, one being based upon the population of the place in which the station is located, and the other upon the horse-power capacity of the generating apparatus of the station. Before 1902 there were in the United States 3,620 central electrical stations, 22.5 per cent. of which were municipal stations. The largest number of stations was in Illinois, followed by Pennsylvania, New York, Ohio, Michigan, Indiana, Iowa and Wisconsin in the order named. The New England states were well supplied with stations. Massachusetts reported the largest number, followed by Maine, Vermont, New Hampshire and Connecticut. Among the Southern states Texas led, with Kentucky, Tennessee and Georgia following. Of the Western states, California reported the largest number of stations, Colorado, Washington, Oregon and Montana being next in order. The power plant equipment showed 5,930 steam engines with 1,379,941 horse-power, and 1,390 water wheels with 4 8,472 horse-power. The generating plant equipment showed 3,823 direct-current constant-voltage dynamos with 442,446 horse-power, 3,539 direct-current constant-amperage dynamos with 195,531 horse-power, 5,122 alternating and polyphase dynamos with 987,003 horse-power. The line construction had 107,263 miles of mains and 17,880 miles of feeders. For the service line equipment there were 582,689 meters, 575,004 of these being mechanical and 7,685 chemical. The aggregate of arc lamps of all classes was 385,698, of which 86.8 per cent were operated from private stations and 13.2 per cent. from municipal stations. In addition to the light supplied by central stations, the street

railways operating electric lighting stations reported 33,863 arc lamps, making a total for the United States of 419,561. The average output of current per day for all stations was 6,960,783 kilowatt-hours, making a total for the year of 2,507,051,115 kilowatt-hours. Among the private stations the totals for New York are at the head; among the municipal stations, Illinois leads.

Association of Edison Illuminating Companies.—The 26th convention of the Association of Edison Illuminating Companies was held at Bluff Point, Lake Champlain, N. Y., September 12, 13 and 14. The meeting was well attended by delegates from all parts of the country, and following its usual practice, the Association held two sessions daily—morning and evening. The rule of the Association of sitting with closed doors was adhered to, and whatever information was divulged was given through a press committee. Reports of the executive committee, meter committee, storage battery committee, lamp committee, National Code Committee and steam turbine committee were presented Tuesday morning and were followed by a paper on "The Practical Operation of the Nernst Lamp," by W. T. Morrison, of New York. Other papers presented were as follows: "The Use of Small-Sized Carbons in Alternating-Current Arc Lamps," by G. N. Eastman, of Chicago; "A New Rotative Test Meter," by W. J. Mowbray, of Brooklyn; "Experiences with Tests on All Kinds of Lamps for the Past Year, Including Nernst Lamps," by Dr. C. H. Sharp, of New York; "Practical Experience with Steam Turbines," by J. A. Radford, of Chicago; "Improvements in Steam Turbines," by W. L. R. Emmet, of Schenectady; "Methods of Starting up Large Interconnected Systems Quickly After Partial or Total Shut-Downs," and "Instruction and Training of All Operating and Construction Men Who Work on High-Potential Apparatus and Connections," by W. F. Wells, Brooklyn; "Relative Advantages of 25 and 60 Cycles, Seen from the Standpoint of the Central Station Rather Than the Power Transmission System, Pure and Simple," by P. Torchio, of New York, and W. C. Eglin, of Philadelphia; "Magnetite Lamps and Mercury Vapor Arc Lamps and Mercury Arc Rectifiers in Connection with Electric Light," by C. P. Steinmetz; "The International Electrical Congress at St. Louis," by J. W. Lieb, Jr., of New York; "Coal Handling and Storage of the Edison Electric Illuminating Company at the South Boston Station"; "Notes on Sales of Electric Power," by E. W. Lloyd, of Chicago; "The Relation of the Central Station to the Motor-Driven Refrigerating Machine," by G. W. Goddard, of Philadelphia; "The Relative Merits of Discharging Batteries in Edison Systems Through Reversible Boosters and Through End Cell Switches," by Gerhard Gottling, of Boston. Mr. Joseph B. McCall, of Philadelphia, was re-elected president and will thus serve a third term.

CENTRAL STATION ENGINEERS—XII.

Charles R. Huntley.

Charles R. Huntley, second vice-president of the Buffalo General Electric Company and one of the pioneer electrical men, was born in Winfield, Herkimer Co., New York, on October 12, 1854. His early education was received in the district school and afterwards when his parents moved to Utica, New York, he entered the Utica Academy. After graduating he entered a hardware firm where his first business training was acquired, and he subsequently became identified with the firm of Remington & Sons, manufacturers of the Remington guns and typewriters of that name. Late in the 70's he settled at Buffalo, New York, and in 1878 became general agent of the

CHARLES R. HUNTLEY.

Standard Oil Company, of Pennsylvania, and remained with that corporation in their oil interests to 1883. For the next five years he conducted a brokerage business in Bradford, Pa., and in 1888 he again came to Buffalo as the representative of his former employers, looking after their interests in the Brush Electric Light Co., which subsequently became the Buffalo General Electric Company, of which he is now, and has been, for several years the general manager. Mr. Huntley possesses unmistakable lines of strength. He knows how to juggle with minds and figures; knows how to plan and win, and above all, knows how to handle men. A thorough knowledge of human nature is his, and this combined with business keenness and pleasing social manners has contributed much to his success. He was one of the most valued employees of the Standard Oil Company, in whose service are enlisted many strong and capable men. Mr. Huntley has served as chairman of the Executive Committee of the National Electric Light Association and was elected president at the Providence Convention held in February, 1891. He is a prominent citizen of Buffalo, and has been identified with all progressive movements.

New Haven Railroad Adopts Single-Phase Motors.—The New York, New Haven & Hartford Railroad Company has contracted with the Westinghouse Electric & Manufacturing Company for twenty-five locomotives to be used for high-speed passenger service. The motors will be of the single-phase, commutator type, which can be used with direct current, so as to operate over the section now being installed by the New York Central & Hudson River Railroad. The New York, New Haven & Hartford Railroad utilizes the tracks of the latter company between Woodlawn and the Grand Central Depot in New York City, and for a time the electric service will be confined to this section. Each locomotive will have four gearless motors permanently connected, two in series. On direct current the motors will be operated in series parallel and on alternating current by voltage control. Each motor will be capable of developing 400 horse-power on direct current.

American Electrochemical Society.—The eighth general meeting of this society was held at Bethlehem, Pa., September 18 and 20. The professional session was held in the chemical laboratory of Lehigh University and some twenty papers were presented. Among those which were of special interest to electrical engineers was one by Lawrence Addicks, which discussed the precautions which must be taken in installing ammeters for measuring very heavy currents, such as used in electrolytic plants, and a paper by Dr. M. Tosh on "Insulating Plants and Their Relation to Electric Traction." The president of the society, Dr. Bancroft, delivered a very interesting experimental lecture on "The Chemistry of Electrochemistry." There was also a lively discussion on the use of the electric furnace in the metallurgy of iron and steel. Some excursions which were planned to points of interest in the neighborhood were somewhat spoiled by the inclement weather, but the visits to the zinc works and the Bethlehem Steel Company's plant in South Bethlehem, as well as to the large cement works in Nazareth, were greatly enjoyed.

Illinois Electric Association.—The Illinois State Electric Association will hold its annual meeting in Peoria, Ill., October 5 and 6. The meetings will be held at the National Hotel, where arrangements have also been made for exhibits. Several interesting papers will be read on various subjects. Important questions will be brought up for discussion, and an entertainment committee will look after the pleasure and comfort of members and visitors. Mr. D. Davis, of Litchfield, is secretary of the association.

AMERICAN ELECTRICIAN

WITH WHICH IS INCORPORATED
Electrical Industries.

CECIL P. POOLE, Editor.

Issued on the first of each month by the

McGraw Publishing Company

114 Liberty Street, New York.

Philadelphia Office..........929 Chestnut Street
Chicago Office..............Monadnock Building
Cleveland Office..............Cuyahoga Building
London Office, Hastings House, Norfolk St., Strand

Address all business communications to AMERICAN ELECTRICIAN, 114 Liberty Street, New York. Matter intended for publication in the reading columns should be addressed to the editor.

Subscription price, $1 per year, postage prepaid, in the United States, Canada, Mexico and Cuba; $2 in all foreign countries. The date on wrapper shows when subscription expires. Subscribers should give their old as well as their new address when requesting a change in address. This should be received a week in advance of the desired change. No copies are kept on sale beyond fifteen months from date of issue, except in bound volumes.

Advertising rates sent on application. Advertisements received for insertion up to the 25th of the month prior to date of publication. Changes in standing advertisements should be received not later than the 15th of the month to insure their insertion in the next issue.

Remittances should be by check, New York draft, express or postal money order, payable to AMERICAN ELECTRICIAN.

Vol. XVII. OCTOBER, 1905 No. 10

The AMERICAN ELECTRICIAN *has the largest circulation of any electrical journal published. Of this issue, 18,000 copies are printed. The total number of copies printed so far this year is 180,000, or an average of 18,000 per issue.*

CONTENTS.

Compound Engines in Isolated Plants.

One of the most noteworthy features of isolated plant practice to-day is the increasing use of compound engines under conditions which but a few years ago would have been considered unfavorable to anything but single expansion machines. Most of these engines are of the non-condensing type, and they are operated in the winter season with either the vacuum or gravity heating system, often in preference to the single-cylinder units which are frequently found in the same plant. The greatest economy from compounding is naturally realized in the summer season, and in cases where the cost of fuel is high; as a general rule also, when the engine is not an auxiliary power unit the coal saving to be expected from using two expansion stages will be realized every time under good management.

The main point is always to operate the compound-unit within its economical range, say from 50 per cent load to full load. At light loads the gains fall off quickly, although steam turbine advocates make claims for a remarkably slow rate of economy loss as the output decreases. If these are vindicated in practice there ought to be a good field for the turbine-generator in isolated plant work as soon as the manufacturers bring out turbines somewhat larger than the direct-current train lighting sets which are now becoming so widely specified in steam railroad service.

Recent designs of compound engines for isolated plant service are remarkably compact, the duplex compound with one cylinder above the other taking up no more floor space than the simple engine of the same capacity. The anticipated increase in maintenance charges has been so small as to cause little or no criticism. The tandem-compound requires a little more floor space, but not enough to cause any anxiety, unless it be in marine work, where every square inch must be utilized. The cross-compound allows a little more flexibility than the tandem and the duplex, and it insures a better distribution of cross-head strains in case it is necessary to run "on one leg." In the plant of a well-known office building in New England a duplex compound engine of 100 kilowatts capacity and a simple engine of the same rated output were recently run upon alternate days for about a week on an electric elevator load of heavy fluctuations, the result being an economy in coal of about 25 per cent in favor of the former. At full load an economy of 30 or 35 per cent is not uncommon, and the increase in fuel consumption only about one per cent to raise the boiler pressure from 80 to 125 pounds. The compounding question is certainly worth looking into, whether or not one decides that the use of such engines warrants, say, a 30 per cent increase in first cost and fits in with the operation of the heating system on all-the-year round economy.

The Expanding Field of the Small Motor.

An impressive point in connection with every exhibition of mechanical appliances and machinery held in these days is the all-around usefulness of the small motor, particularly in the sizes below five horse-power. It often happens that the apparatus shown is designed to be operated by steam, gasoline, oil or water under conditions which are either impossible to duplicate or intolerable on account of the fire risk and atmospheric vitiation in a large hall or pavilion. In such cases electricity solves the problem perfectly, and the displayed mechanism travels its prescribed cycle at any convenient speed desired by means of the simple application of an inconspicuous, cleanly, flexibly arranged and efficient belted or direct-connected motor. Given such an installation, the exhibitor's energies are no longer spent watching for trouble in his moving display; he is free to concentrate his attention upon his visitors and show to the best advantage the ins and outs of his exhibit. Probably in no other way could the operation of gearing and valve motions in automobiles, power boats and heat engines in general be as well shown in detail. The use of the electric fan to increase the physical comfort of exhibits in crowded halls is also worth mentioning.

As a matter of fact, the uses of the small motor are now almost beyond enumeration. In the single field of retail advertising the electric motor can be applied almost without limit. The store windows of every progressive city are alive with devices driven by electric power. In the laboratory the motor-driven "centrifuge" offers an easy method of separating solids held in suspension from their respective liquids; grinders, stirrers, crushers, gas extractors and pneumatic blowers are readily driven by small motors; the dental drill and tiny surgical bone saw are equally dependent upon these prime movers. Musical instruments, phonographs and battery-driven fans for the sick room unsupplied with central station current merely suggest the expanding range of the small motor field.

There is often a tendency on the part of central station men to belittle the very small motor and other relatively minute applications of current to humble purposes. In the light of experience this is certainly poor judgment, for, although the revenue that the central station derives from such sources is insignificant in comparison with its income from large consumers, each new application of electricity in a community widens the public's appreciation of its adaptability to the affairs of life and in the long run opens the way toward larger commercial success.

Alternating-Current Motors in Shop Practice.

In the selection of motors for factory driving the question often arises as to the availability of alternating-current types for the work in hand. Since the early development of motors capable of driving machine tools naturally proceeded along direct-current lines, the opinions held in many quarters to-day are based on failure to realize the extent to which alternating-current machines have been applied in shop practice, or their particular field of usefulness.

There is no question that the direct-current motor has perfectly solved the problem of machine-tool driving under the usual circumstances of factory operation. For work requiring speed changes in increments of 10 or 15 per cent over wide ranges in order to reap the full benefit of high-speed machine-tool steels, the direct-current motor appears to have no superior. Probably the day is not far distant when the designer of alternating-current motors will produce equipment capable of much wider speed variation than present market types exhibit. Nevertheless, the direct-current motor has a strong grip upon the variable-speed field of application, except in installations where the presence of water, explosive gases, metal dust, and other foreign substances make the use of a commutator dangerous or otherwise objectionable. The use of alternating-current motors in such cases entails the employment of some external speed-changing device, for both the induction and synchronous types are essentially constant-speed machines. Fortunately high-speed tool steels are usually operated under conditions not unfavorable to the installation of direct-current equipments. Convenience of manipulation with little effort and loss of time on the part of the workman are essential to the successful use of steels capable of taking cuts at the rate of 100 to 200 feet per minute, but at the present time it is very hard to find any thoroughly satisfactory mechanical variable-speed device on the market. Direct-current control gives the best modern results.

The strong points of the alternating-current motor, as we have pointed out before, are its simplicity, its ability to carry heavy overloads without damage, and its low cost of maintenance. Uniform equipment is a boon in every industrial plant, and the use of a single type of motor in a factory already equipped with an alternating-current isolated lighting plant is a most desirable course. The new shops of the United Shoe Machinery Company, at Beverly, Mass., for instance, illustrate most admirably the advantages of simplifying the electrical installation. Turbine-alternators supply current to the lighting circuits and to induction motors throughout the buildings, not a direct-current machine being used in the shops. The problem of machine driving in this case, however, did not preclude the use of constant-speed motors.

It is not so much a question of group or individual driving, in considering the alternating-current motor for a shop installation, as it is a matter of the speed range required by individual machines. If the work done by a machine or a group of machines does not require relatively fine gradations in speed, the alternating-current machine will handle the situation admirably, even though extremely wide variations in power may be required. Planers, slotting machines, punches, milling machines, shapers, and other equipment in which reciprocating motions are employed generally impose heavy momentary overloads which are prone to cause flashing at the commutators of direct-current motors, while alternating-current motors of the same rated capacity give little or no evidence of the strain. The latter type cannot run away as do compound or shunt-wound motors in case the field circuit is accidentally opened; attendance is reduced to keeping the oil wells filled and to seeing that the rings are operating properly; repairs are easily made in the rare intervals when they are necessary, and in the smaller sizes of motors the starting box is eliminated. The entire range of group driving at constant speed and of individual driving, where the conditions are well known and the quality of material and tool steel fixed, gives the alternating-current motor a field of service on equal terms with its older rival. The fire risk and the element of personal danger both are reduced in a well-designed and installed alternating-current layout. In large plants the advantage of distribution at higher potentials than are feasible with direct-current will frequently decide the choice in favor of the alternating-current motor.

The Central Station and the Small Consumer.

One of the greatest mistakes that a business house can make in these days of keen competition is to discriminate unfairly between its customers. While it is only just that the wholesale buyer shall receive discounts greater than those accorded the small purchaser, it is very bad policy to treat the latter as though his transactions were of no importance. Most progressive retail establishments realize this point, with the result that from the department store to the bank the small account receives the same consideration as the large one.

In the central station field there is still a tendency on the part of many managers to look upon the small user of power as a customer of little consequence. On this account very little energy is expended by such managers in seeking new business of the smaller kind. Often the solicitor's time is fully occupied with larger propositions, and there is a feeling that it will not pay to increase the force simply to persuade Jones to run his little back-alley carpenter shop by a 3-h.p. motor or Smith to install a couple of electric fans in front of his soda fountain. Why should the company pay the cost of educating old Dr. Phosphorus up to the point of putting half a dozen 16-c.p. lamps into his dingy, gas-illuminated den which has long been blackened by the fumes of forty years' chemical experiments? Very likely some of these "small fry" will buy a couple of dollars' worth of current in a month, and "it is actually a question if it will pay to tie up the equipment."

Such a point of view as this belongs in the heathen lands where life proceeds from day to day on the basis of the cocoanut and the loin cloth. It has no place in the central station industry, where every manager is in business for all there is in it, and therefore is eager to increase his load by every legitimate means. To be sure, there is often small profitable revenue gained from the customers whose requirements are very limited, but it should not be forgotten that when a customer has learned to appreciate the advantages of electric lighting and electric motors over other forms of illumination and power he is pretty sure to enlarge his facilities sooner or later as his business expands, and usually encourages others to follow suit.

CONSTRUCTION OF A JUMP SPARK COIL.

The successful construction of a jump spark coil for gas engine ignition purposes is rather difficult for an amateur because of the high-grade insulation which is indispensable to satisfactory operation. The mechanical part of the construction is simple to the last degree. The data given herein will enable any fairly capable amateur to build an excellent coil provided he is sufficiently patient and painstaking to insure proper insulation; several coils have been constructed from the data here given and

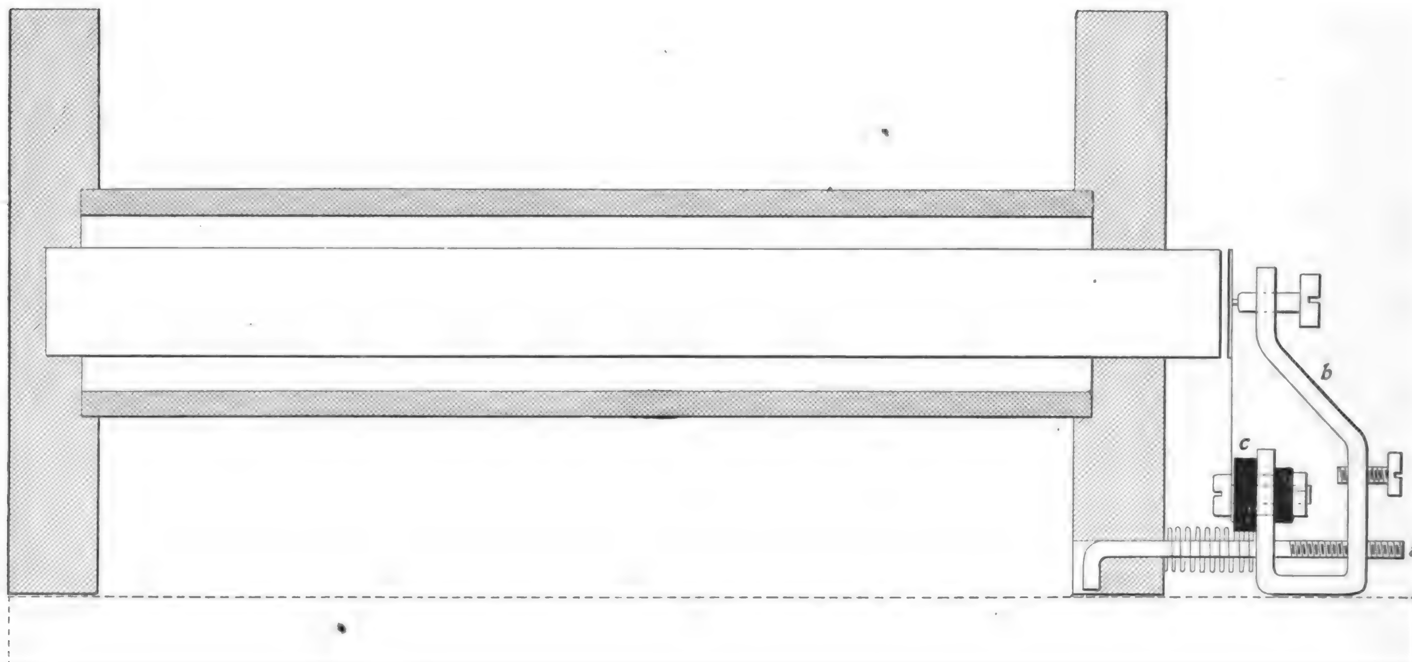

FIG. I.—SECTIONAL ASSEMBLY DRAWING OF JUMP SPARK COIL.

all of them excepting one have been in continuous and perfectly satisfactory operation ever since they were finished. The one exception failed because it was not properly insulated.

The core is built up of No. 22 soft iron wires 8 in. long; these must be thoroughly annealed after being cut to length. The bundle is 3/4 in. in diameter. The core is assembled in the heads, the wires being "coddled" into position when the core approaches normal size, and the final wires being inserted one by one until no more can be got in. As the sectional assembly drawing, Fig. 1, indicates, the rear end of the core does not pass through the back head, but sets into it 3/8 in.; it does pass through the front head and must be tied tightly with fine linen thread as close to the head as possible so that the head may be removed and replaced without trouble. The core must project 3/8 in. beyond the outer surface of the front head.

The heads must be made of hard wood 5/8 in. thick. Each head is 4 in. square and counterbored 1/8 in. deep on the inner face to take the rubber tube which separates the primary and secondary windings This tube is 1 3/16 in. bore with wall 3/16 in. thick, so that its outer diameter is 1 9/16 in.; it is 6 7/8 in. long, and the ends must be perfectly square with the bore (at right angles to it). After the heads have been shaped up and bored, they must be boiled in paraffine; this is accomplished by simply melting paraffine wax in a vessel and immersing the heads in the melted wax, the latter being kept boiling for an hour. The heads are then to be taken out and allowed to cool in clean surroundings.

After assembling the core in the heads, the latter being set exactly 6 5/8 in. apart, the core should be taped with a good grade of adhesive insulating tape; high insulation here is not essential. Then the primary coil should be wound on, starting the first layer at the front head with the end of the wire projecting two or three inches through a hole in that head close to the core. This coil consists of two layers of No. 16 double-cotton-covered magnet wire, the turns being wound as closely as possible, of course. The finishing end of the wire should be tied

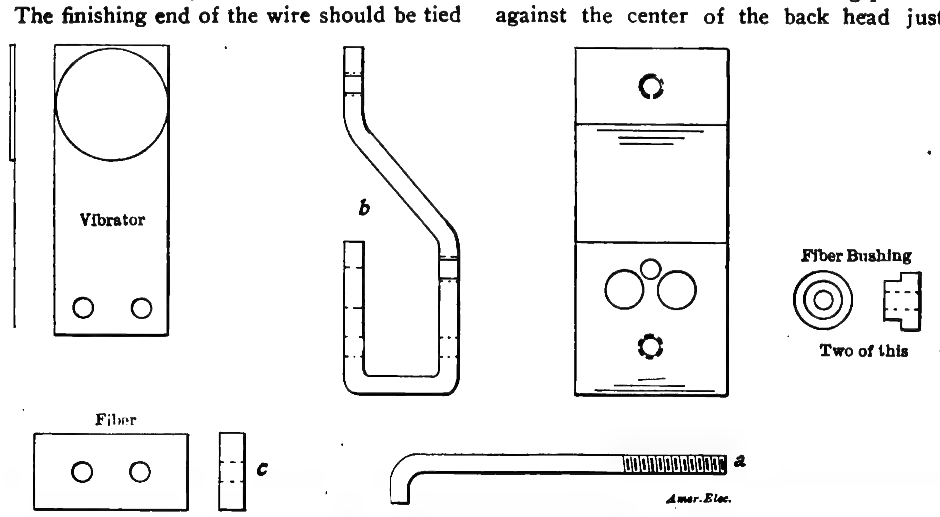

FIG. 2.—DETAILS OF SPARK COIL.

down temporarily to the coil. The front head is then pulled off the core, taking care that the starting end of the primary wire pulls through the hole in the head and does not unwind the inner layer. The rubber tube is then slipped over the primary coil and seated in the counterbore in the back head, and the front head is put back in place, this time permanently. The two ends of the primary winding must be threaded through holes in the front head as it is put back, and these ends should be protected by woven cotton sleeves, such as those used on the leads of direct-current dynamo armature windings. Just before pressing the front head "home" against the end of the rubber tube, the end of the primary coil should be lightly varnished with shellac, including the terminals and their sleeves; this will stiffen the end convolutions of the coil and tend to prevent tearing them down if it should be necessary at any future time to take off the front head again.

The core should then be chucked in a lathe, the front end being held in the chuck and the tail center of the lathe being pressed against the center of the back head just enough to indent the wood and keep it central. The supporting pin, *a*, of the vibrator mechanism should then be set into the hole in the front head and held in place temporarily by a small set collar while the secondary winding is put on. This winding consists of 1 1/2 pounds of No. 33 double-

silk-covered wire. The starting end should be soldered to a piece of No. 16 copper wire and the latter threaded through the back head and attached to one of the secondary binding posts, which must be screwed into the back head, preferably into the face of the block rather than the edge.

Before proceeding with the winding of the secondary coil both of the heads should be faced with hard rubber about 1/32 in. thick. The last layer should end next to the back head and the final end of the wire be threaded through a small hole in the head and carried to the other binding post. The binding posts are not shown; ordinary telegraph instrument posts should be used, such as the binding posts used on standard sounders. In winding on the secondary wire, tension should be applied to it by means of rollers in order to avoid damaging the insulation by friction; six or eight grooved rollers should be mounted on spindles and the wire threaded through them backward and forward so as to obtain a braking effect with the least possible amount of friction on the wire.

The vibrator consists of a piece of flat spring steel 1⅞ in. long, ¾ in. wide and No. 28 gauge in thickness, with a disc of soft steel ¾ in. in diameter sweated to its free end; the disc and the end of the spring must, of course, be thoroughly tinned before attempting to sweat them together. The spring is attached to the mount, *b*, by means of two No. 8 brass machine screws and nuts, insulated from the mount by a flat piece of hard fibre, *c*, 3/16 in. thick, ½ in. wide and 1 in. long, and two fibre bushings

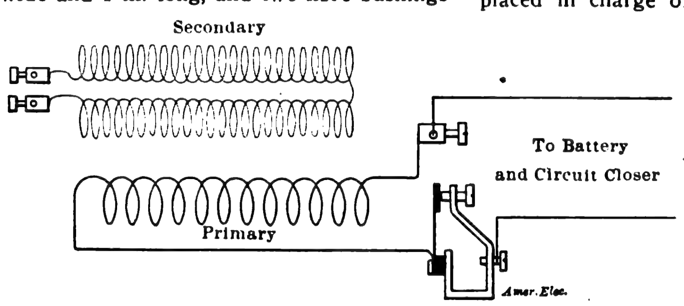

FIG. 3.—DIAGRAM OF CONNECTIONS.

set into the holes in the mount and having heads ⅛ in. thick. (See Fig. 2.) The mount, *b*, is made of strip brass ⅛ in. thick, 1 in. wide and 3⅝ in. long. The construction and arrangement are so simple and obvious that further explanation is scarcely necessary. The contact screw is an ordinary telegraph relay screw with a platinum point; it can be bought from any maker of telegraph instruments for a few cents. A round milled nut should be fitted to the thread on the outer end of the supporting pin, *a*, so that it turns somewhat stiffly; otherwise a jam nut will be necessary. The spring surrounding that part of the supporting pin between the front head and the mount may be made of No. 18 spring brass and it should be wound on a mandrel the same size as the pin, so that it will be slightly larger in the bore when released just after being wound.

The complete coil should be boxed in by means of hard wood strips ½ in. thick screwed to the edges of the heads; the bottom strip must project beyond the front head far enough to serve as a seat for the horizontal part of the vibrator mount, as indicated by the dotted lines in Fig. 1. After the bottom and the two side strips have been screwed on, the box thus formed should be filled with melted paraffine wax; then the top strip may be screwed in place and the coil is finished. Fig. 3 is a diagram of connections.

ISOLATED PLANT ENGINEERING.

BY JAMES F. HOBART.

The lot of the engineer in charge of a small or medium sized isolated steam plant is frequently far from a happy one. Frequently he is handicapped by having an "owner" who "knows it all" and who dictates to him without sense or reason. The oil, waste, fuel, tools and appliances are often purchased without his opinion being asked as to what is desirable or even necessary. Sometimes, however, it is the engineer who is to blame, and not the "owner." There are many engineers who will use no exertion to better themselves or their surroundings; insomuch so that it is useless to tell them how to improve things or how to make the best of their condition.

The writer knows of one man in charge of a small steam plant who for two years shoveled coal from a dirt floor in front of the boiler rather than put down a brick pavement; all the material being on hand and available. On the other hand may be noted the example of a man who was placed in charge of a homely old engine covered with rust and dirt and located in a shed. In less than two years this engineer had transformed the old shed into a brick-walled structure with a concrete floor; the engine had been nicely painted, and the interior of the building would not suffer by contrast with more pretentious engine rooms.

Next to having no voice in the selection or purchase of supplies, is the irritation of having an incompetent fireman who is hired by the "owner" and over whose dismissal the engineer has no control. When a man is sent to fire who will open the furnace doors and begin to break up a soft coal fire with a slicebar without first looking to see where the water level stands, he needs watching, for he is a dangerous man to have around.

Sometimes the same man, or one like him, will shut off the feed to a boiler without stopping the pump or opening some other passage for the water. Another trick is to leave a bed of coal, ashes or clinkers anchored against the bridge wall while there is a pile of blazing coal in front of the furnace close to the doors. This kind of work is not always limited to the fireman; it can be recognized in the engineer who cleans the brass work of an engine only where it happens to be in front. Valves made bright on top only, do not look well when the hand-wheel is turned half way over and dirty surfaces brought to light. When a man is packing rods or stems, note whether he takes out the old packing and puts in new, or whether he forces in another ring or two on top of the old packing, and then pretends to have done a good job. The first method never cuts rods—the second should never be imitated.

There are some "dont's" for the engineer as well as for the fireman: If there is a slight knock or pound in the engine which you intend to take up, don't delay doing it until just before the engine is started in the morning. When the engine is warm, say after shutting down at noon or at night, is the proper time to make such adjustments, for then the several pieces are expanded and the adjustment can be made as close as is necessary without having to make guess allowances for expansion. Many an engineer has come to grief by setting up connections when the engine was cold.

Another point for the isolated station man is in the care of belts and pulleys. Never let dust accumulate in pulleys. Have them cleaned at least monthly. A belt, be it made of rubber, leather or cotton, requires as much care as a journal bearing or the inside of an engine cylinder. A belt left to itself will never do the work intended by the engineer. Every inch in width of a good double belt is expected to exert a continual pull of 88 pounds when at work; but if it is not kept at the proper tension it will be folly to look for the expected results. To obtain 88 pounds effective pull the length and slack of the belt, together with its adhesion to the pulley, must be such that at least 44 pounds pull per inch of width will exist in the slack or return fold of the belt.

When a belt is stretched between two horizontally placed pulleys, the distance apart of the pulleys, the length and weight of the belt per foot, determine the tension of the belt and the pull it will exert when running. If a belt sags just right to bring the proper pull of 88 pounds on the working side or fold when the belt is running, and is clean and soft enough to obtain the proper hug or "bite" upon the pulleys, then it will easily transmit the amount of power it was figured for. If, on the other hand, the belt is allowed to become hard, dust filled and too slack, then there will be slipping between the belt and one or both the pulleys, the necessary power will not be transmitted and the life of the belt will be short and unsatisfactory.

Another bad error which is frequently made in the design of isolated plants, is the use of pulleys far too small for the work expected of them. Compare the work done, and the cost of pulleys and belts necessary to transmit 100 horse-power between shafts 16 in. apart with pulleys 48 in. by 16 in. in one case, and 63 in. by 12 in. in the other. Both sizes of pulleys are designed to transmit 100 horse-power, and the list price of the 48-in. by 16-in. pulley is $60.20 each, and the 63 in. by 12 in. set is $73.30 each, or $120.40 and $146.60, respectively. The length of belt in either case will be 44.6

ft. and 48.5 ft., respectively. Assuming the 16-in. belt to cost $4 per foot and the 12-in. belt $3, the cost of the belts will be $178.40 and $145.50, making a total cost for each installation of $238.60 and $278.80. Thus, the large pulleys and narrow belt cost $40.20 more than the small pulleys and wider belt, but when it comes to renewals it is another story, for it will cost $32.90 more to renew the 16-in. than it does the 12-in. belt, hence the large pulleys and narrow belt should be specified for economy.

One thing in particular, which it pays well to look after, is the influence of weather conditions upon belts. Leather in its natural state is very susceptible to moisture and to climatic conditions. Rubber and "Gandy" (impregnated stitched cotton) belts are also affected by dry or wet atmospheric conditions, but it acts in different ways with the materials named. When a leather belt is exposed to damp air, the first result is it shortens in some instances sufficient to cause hot bearings in shaft or machine. If the moisture is long continued or increased to an extent that the belt becomes wet instead of damp, an amount of stretching will be observed for the reason that a leather belt, when wet, is more easily stretched than when dry. Hence the apparent paradoxical effect of moisture upon leather belts whereby they first shorten on exposure to moisture and then stretch, sometimes to an alarming extent. The remedy is to fill the leather with certain oils or other substances which will render the leather proof against any humidity changes likely to be met with. The natural waterproofing for leather is neatsfoot oil, but almost any oil which will not evaporate will do. An engineer of the writer's acquaintance uses cylinder oil on the governor belt of his engine, and has never had the belt go slack or tight, no matter how the humidity conditions might vary. In many machine shops, the lathe belts are soaked with black lubricating oil and they do business right along to a capacity far above 88 pounds for inch of width (66 pounds for single belts) and are never too slack or too tight. There are several excellent belt dressings in the market which will protect leather belts from humidity if properly and plentifully applied.

Rubber belts are supposed by some to be impervious to water, but this is a mistake. When a rubber belt is new, it is practically impervious to water, but as soon as the belt begins to run over pulleys, the rubber covering alternately stretches and compresses, and soon opens to a certain extent and air is drawn into one side of the belt. As a certain percentage of moisture goes into the belt with the air it is certain to come in contact with the cotton body of the belt. Almost any oily substance, which will keep out moisture, seems to soften the rubber covering and thus injure the belt. There is, however, one substance which works very well on rubber belts as well as leather and cotton ones. This substance will be referred to later.

Belts made of cotton duck afford about the best and cheapest method of transmitting power known to the engineer outside of electricity. But cotton is very susceptible to humidity and cannot be used without ample protection from the least variation of humidity in the atmosphere. Otherwise, cotton duck, folded and stitched, or woven to the required thickness would make the ideal belt for any service or condition.

The usual cotton belt is filled with either linseed oil or a substitute or else with a mineral oil or paraffin substance. The writer prefers the latter. The linseed oil stuffing oxidizes and becomes hard, whereas the paraffin filling does not oxidize and causes the belt to remain soft and pliable for a long time. If measures are taken to replace the wear of the belt filling as fast as it disappears, there is no other belt which for efficiency and cost can approach the stitched cotton belt. As stated, there is a certain substance which protects not only cotton belts but leather and old rubber belts. The writer refers to the substance known as "cling surface."

The height of perfection is reached when cotton belts are procured "in the white" before they have been impregnated. Then, the substance named will penetrate quickly and thoroughly and a belt will be obtained which leaves nothing to be desired. It is far better than either leather or rubber, for any purpose to which belting can be applied and it is equally good for rope transmissions of power. The writer has personal knowledge of the performance of belts impregnated in this manner which leads him to consider that for all isolated station work, engine belts included, nothing better has yet been brought to trial than the plain stitched cotton belt filled with the substance named.

The writer has been surprised by the almost universal practice of owners and some engineers in the matter of boiler feeding. Thirty plants of which he has knowledge are supplied with a belted boiler feedpump, either driven from the engine shaft or from the main shaft, but in almost every one of the plants in question, the power pump has been permitted to remain inactive. Each of the plants is also provided with a duplex steam pump, and in some instances an injector, making three methods of feeding the boiler; but the steam pump or the injector are almost invariably used at considerable greater expense to the owner, notwithstanding the fact that the power pump was furnished with a bypass by means of which and a single valve the pump could run all the time and a constant and uniform stream of water sent into the boiler to replace evaporation. In spite of the convenience noted, the cheap and efficient power pump remained inactive and the boilers were fed with the expensive steam pump and an occasional injector.

There are several ways of cleaning fires depending upon the kind of fuel burned; but assuming that anthracite slack is used with enough bituminous mixed to make it burn well, it is the writer's practice when plain grates are in use to put in a good firing of fresh coal and let it get up to a good clear red. The damper is then closed and the live coal raked over on one side of the grate, then the ash and clinker are raked from the other half of the grate. This being done, the burning coal is moved to the cleaned side of the grate, and the remaining ashes hoed out, the live coal is then spread evenly over the whole grate and the damper opened. As soon as the coal becomes bright red the boiler should be fired rapidly again, and as soon as it is well brightened up it should be fired to the usual depth.

A man can clean a fire in a single boiler in this way and not have the pressure drop more than 8 or 10 pounds during the operation. If particular attention be taken to close the damper the drop in steam pressure will be much less than if the damper be left open. It is the cold air blowing directly against the boiler shell which lowers the steam pressure. With the damper closed the heat contained in the setting and in the red hot fuel will go far to keep the pressure up until the fire has been fully cleaned. It is not to be understood that the damper is to be shut so tight that all the hot gases puff out into the face of the man who is doing the cleaning. If the damper is very tight fitting it should be left open a trifle. When several boilers are operated in battery it is an easy matter to cut out one boiler by closing the damper, then as much time may be taken as is necessary for cleaning, since the other boilers will keep the pressure up. When a single boiler has to have its fire cleaned, quick work must be done.

Another method of cleaning a fire is as follows: The fireman fires one side, letting the other side get low. As soon as the fired side is burning freely the low side is cleaned and some fresh coal thrown upon the grates, then the live coal is pulled over upon the green coal and allowed to come to a bright red. The remaining side of the grate is then cleaned as soon as it has burned down, some green coal is spread there, and the fire again distributed evenly over the grate, after which it is fired lightly and allowed to come to its normal condition for a run of several hours to the next cleaning time.

The chief objections to the latter method of cleaning a fire, are the number of operations which have to be performed and the great length of time the fire is partially out of complete maximum service. It will require a half hour to clean a fire by the second method, while seven to ten minutes will suffice for cleaning by the first method.

International Association of Municipal Electricians—At the tenth annual convention of this body at Erie, Pa., August 23, 24 and 25, the following officers were elected: President, Jerry Murphy, Cleveland, Ohio; vice-presidents, William Crane, Erie, Pa.; H. R. Allensworth, Columbus, Ohio; B. A. Blakey, Montgomery, Ala.; F. A. Cambridge, Winnipeg, Man.; secretary, F. P. Foster, Corning, N. Y.; treasurer, C. E. Deihl, Harrisburg, Pa. Executive Committee: T. C. O'Hearn, Cambridge, Mass., chairman; A. S. Hatch, Detroit, Mich.; J. B. Yeakle, Baltimore, Md.; Louis Gascoigne, Detroit, Mich.; W. M. Petty, Rutherford, N. J.; James Grant, New Haven, Conn.; W. H. Thompson, Richmond, Va.; W. Y. Ellet, Elmira, N. Y. Finance Committee: D. D. Clayborne, J. F. Macdonald and H. C. Bundy.

HIGH TENSION CIRCUIT BREAKING DEVICES.

BY W. T. FERNANDEZ.

With the development of high-tension transmission systems, the necessity for an automatic device to break a high-tension circuit under short-circuit conditions set engineers at work on the perfection of such a device. Various air-break, sand-break and fuse-break devices were tested with unsatisfactory results, until it became evident that a radical departure from existing methods was necessary to attain the desired results; hence the oil-break switch.

As several types of oil-break switches are in general use, the mechanical and electrical features of each will be considered in its turn. The compressed air type will be eliminated as obsolete and the first form of the General Electric type "H" oil switch will be described.

This switch consists of an ingenious combination of motor and spring drive. The truss, carrying the circuit-closing spindles, is actuated by a crank connected to the motor drive by a worm gear, which in turn is actuated by the magnetic thrust clutch illustrated in Fig. 1. When the operating current is applied, the clutch, *C*, is thrown into contact with the clutch, *CC*, by the thrust rod, *R*, which is driven forward by the solenoid.

The motor is series wound and is connected in series with the solenoid, so that the clutch is interlocked the instant the motor starts, carrying the crank attached to the gear wheel, *G*, over its center, thus releasing the top spring which bears on the truss, forcing the latter downward. The crank shaft is connected to the gear wheel through a friction clutch which, while it permits the shaft to travel faster than the gear wheel in one direction, will not allow it to be turned backward, so that the action of the switch is progressive and always in one direction. The closing motion is performed by a one-half turn of the crank shaft and the succeeding opening motion by a second half turn of the crank shaft.

The travel of the switch is determined by a limiting device consisting of three movable contacts, usually called fingers, actuated by three cams mounted on the crank shaft and so set that the master finger (1) will make contact with a small bus-bar an instant before the closing finger (3) is released; thus continuing the circuit until its actuating cam releases it. At the same instant finger 2 is thrown into contact with the bus-bar, thus furnishing a path for the current for the opening motion. (See Fig. 3.)

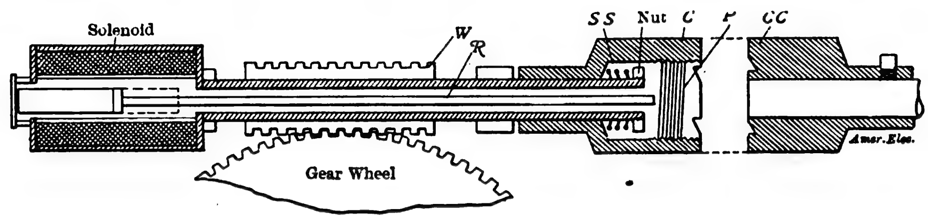

FIG. 1.

It will be evident from the action of the cams and fingers, that the limiting feature is finger No. 1 and that the switch's travel is determined by the adjustment of the cam (Fig. 6) actuating that finger, as the mechanism is disconnected from the motor by the release of the clutch, *C*, the instant the operating circuit is opened by the master finger. If that finger remains on the bus-bar too long, the crank will be carried past the bottom center and the mechanism thrown upward by the bottom spring to the open position. With the Niagara type of control switch (Fig. 3) operating current will be applied as soon as finger 3 is closed on the bus-bar, thus throwing the switch in again. The rapid opening and closing of a switch (commonly called "pumping") is dangerous to both switch and apparatus, and, therefore, the adjustment of the master finger should be carefully noted. A center mark is indicated on the gear case and a pointer on the crank shaft indicates how close the crank is to center in both the open and closed positions. That pointer should always be set at least 1-16 of an inch back of center (the term back of center is used as indicating the direction reverse to the pointer's travel).

It will be seen in Fig. 1 that the half of the clutch, *C*, mounted on the end of the worm shaft is movable, so that it may be thrust forward by the rod, *R*, under the influence of the solenoid, which drives it against the screw plate, *P*, in front of the clutch jaw. When the operating circuit is opened by the master finger, the clutch jaw and thrust rod are drawn away from the motor clutch jaw by the spring, *SS*, thus stopping the mechanism and allowing the motor to slow down gradually.

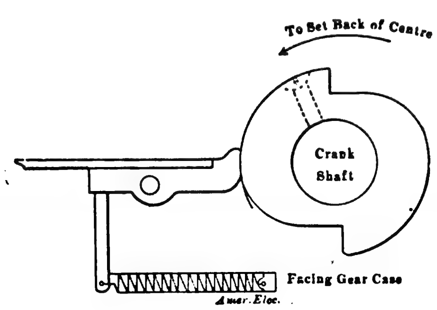

FIG. 2.

It sometimes happens that the screw plate, *P*, works loose, lessening the travel of the movable clutch jaw to such an extent that it will not properly interlock with its fellow on the motor shaft, with the result that the jaws will be stripped from one or both halves of the clutch. A minimum clearance of 1-16 of an inch should be allowed between jaws and when regular inspection—which should be made once every twenty-four hours—reveals by the use of a gauge, a lessening of that clearance, the motor should be taken down and the screw plate examined. Another cause of trouble on this type of switch is that the oil used to lubricate the worm shaft and gear wheel, works down into the dogs of the friction clutch, causing them to slip and allowing the mechanism to fall back from the open position. A mixture of good grease and graphite applied sparingly once a month will keep the parts in good condition and prevent the dogs slipping. The newer type "H" differs slightly in mechanical details from the type described, and is equipped with a clutch which is entirely magnetic. (Fig. 4.)

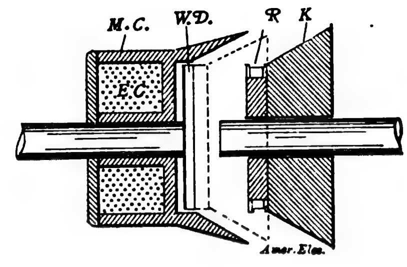

FIG. 4.

The end of the worm shaft, *W*, is turned into a disk, *WD*, housed in the casting, *MC*, which carries an energizing coil, *EC*, connected in series with the switch motor. On the motor end is mounted a movable armature, *K*, keyed so as to move back and forth freely on the shaft. This armature is fitted on the inner side with a wooden ring, *R*, fastened to it by a binding similar to that used for binding the coils of an armature, and projecting about 1-64th of an inch beyond the core. This ring forms the friction element of the clutch.

When operating current is applied, the coil, *EC*, is energized as the motor starts, and draws the armature, *K*, into contact with the disk, *WD*, thus transmitting the motion of the motor to the worm shaft and mechanism of the switch. The release of this type of friction clutch is determined by the master finger as in the mechanical clutch type, but has a few faults peculiar to itself.

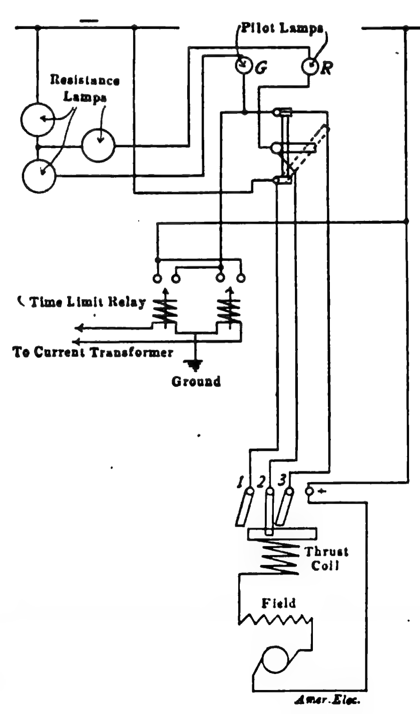

FIG. 3.

The binding band of the wooden friction ring will sometimes work loose and permitting that ring to turn, will throw the switch over the center, when it will be thrust downward by the top spring, but will not

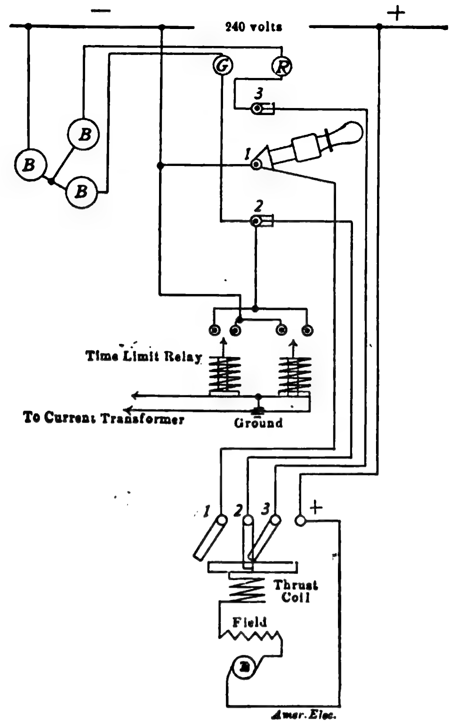

FIG. 3-A.

bind with sufficient force against the disk, *WD*, to carry the switch home. The only remedy is to rebind the wooden ring, and the binding must be applied with force. It will be found that after such a condition has arisen that the face of the friction ring has been worn smooth and will not hold firmly at once, if the face of the ring is roughed up a trifle with coarse sandpaper, the clutch will take hold and do its work, after being rebound. Care should be used when oiling the mechanical parts of this type of switch that no oil reaches the clutch

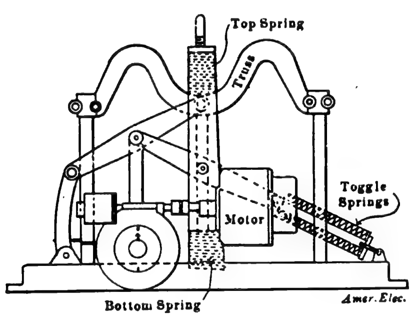

FIG. 5.

faces, as oil will render the clutch inoperative, and necessitate the thorough cleaning of those parts and the roughing of the wooden ring with sandpaper to restore the necessary friction between the two faces of the clutch.

Another source of trouble on the two types mentioned is an unbalance in the top and bottom thrust springs, which sometimes exists on account of the impossibility of tempering any two springs exactly alike. The master finger may be set to cut off at the proper point on the opening motion but will carry over the bottom center. As a rule, the master finger may be set far enough back of the top center to give a safe margin on the bottom center, but in exceptional cases it will be found necessary to take up on the toggle springs (Fig. 5) whose function is to render the opening motion more rapid than the closing motion—to compensate for the unbalance of the thrust springs. In some rare cases even this expedient is not sufficient and the switch will still carry over the bottom center; the only remedy then is to split the cam which actuates the master finger so that two independent cut-offs are obtained. With the single cam, the top cut-off bears a certain definite relation to the bottom cut-off, but if the master finger cam is split, each point of cut-off may be set independent of the other and any unbalance of either the top or bottom spring thus adjusted. Pumping may also be caused by a variation of the e.m.f. of the control current, and in unavoidable cases the switch should be set at the maximum voltage carried.

The oil pot contact is illustrated in Fig. 6. The bottom contact is set into a space provided for it in the bottom of the oil pot and is held therein by a screw ring. The four sections of the contact are held together by two spiral springs, formed into a circle and sprung around the outside of the contact blocks. If one of these springs breaks, a loose connection between the spindle and bottom contact results, causing heating of the oil in the pot. Cleaners should, therefore, be instructed to feel each pot and report any unusual temperature. Where doubt exists as to the heating of a certain connection, place a small lump of paraffine on the end of a stick of seasoned wood and touch the part while it is carrying load; a softening of the paraffine indicates the faulty

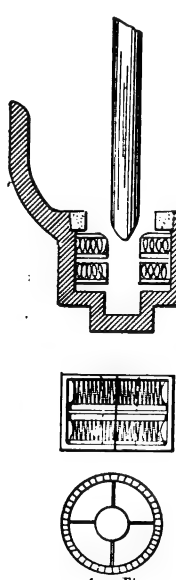

FIG. 6.

connection. The wiring diagram shown in Fig. 3A, illustrates the most approved method of control for type "H" switches. The control switch is always open, so that if the oil switch "pumps" it can only return to its original position and cannot continue to open and close as in the Niagara type, since when the operating finger of either the opening or closing motion comes into contact with the bus-bar on the switch, it is always "dead" after the initial operation has been performed.

The direct-current circuit of the time limit or overload relay is slightly different from that used with the Niagara control switch. Instead of energizing a tripping magnet, the tripping circuit of the relay is closed directly through the oil switch wiring and throws open the switch without any secondary device. The simplicity, as well as the safety, of this method of control will be understood by a study of the wiring diagram Fig. 3A. It will be noticed that the pilot lamps shown in Figs. 3 and 3A indicate by becoming luminous whether the oil switch is open or closed.

The object of connecting other lamps in series with the pilot lamps is to prevent the possible opening of the switch by short-circuiting the filament of the pilot lamp. It is impossible by short-circuiting any one of the lamps to open the switch, and the method is safer than the introduction of wire resistance in the pilot circuit since the short-circuiting of that resistance would blow the pilot lamp and open the oil switch.

PRACTICAL NOTES ON BOILER FEEDING APPARATUS.

BY CHARLES L. HUBBARD.

Feed-Water Heaters.

Feed-water heaters are employed for two important reasons: First, if cold water is introduced into a boiler in any considerable quantity the cooling effect will cause an unequal contraction of the plates, which is likely to produce leaks at the joints. It also tends to reduce the steam pressure and necessitates more rapid firing for a time after feeding, unless the load upon the engines is practically constant, so that the feed valve can be set to supply a uniform quantity of water continuously.

Second, feed-water heaters can nearly always be arranged to utilize exhaust steam or waste gases from the furnace, so that a substantial saving in fuel is gained by their use.

The percentage of saving in fuel by heating the feed water with waste products is expressed by the equation

$$\frac{100\ (I_2 - I_1)}{L + (I_3 - I_1)},$$

in which

I_1 = initial temperature of the feed water entering the heater.

I_2 = final temperature of the feed water leaving the heater.

I_3 = temperature of the steam at boiler pressure.

L = latent heat of evaporation for steam at boiler pressure.

Example.—What will be the saving in fuel by using an exhaust steam feed-water heater when the initial temperature of feed water is 60°, the attainable final temperature 205°, and the steam pressure in the boilers 80 pounds, gauge? From a steam table the temperature of steam at this pressure is found to be 324° and the latent heat of evaporation 886°. Substituting these values in the formula:

$$\frac{100\ (205 - 60)}{886 + (324 - 60)} = \frac{14{,}500}{1{,}150} = 12.6\%$$

This is true because the total heat required per pound of steam is that necessary to raise the temperature of the feed water from 60° to 324°, which is 324 — 60 = 264 heat units, plus that required to evaporate it into steam at this temperature, which is 886 heat units, making a total of 264 + 886 = 1,150 heat units. The saving made by heating the feed water from 60° to 205° is 205 — 60 = 145 heat units. Therefore, the gain in per cent is $\frac{145 \times 100}{1,150} = 12.6$.

With the most economical multiple expansion engines only about 18 per cent of the heat stored in the steam leaving the boilers is transformed into work, and in the majority of engines probably not more than 10 per cent is utilized. If we assume 15 per cent as an average, this leaves 85 per cent of the heat in the total amount generated, available for heating purposes, and of this amount only a comparatively small proportion can be used for feed-water heating under ordinary conditions. In office buildings, factories or other buildings having their own power plant, this remaining portion is usually employed for warming and ventilating purposes.

The proportion of heat in the exhaust steam which can be used for feed-water heating may be easily determined as follows: The latent heat of evaporation for steam at atmospheric pressure is 966 heat units: that is, each pound of steam gives out 966 heat units when it is condensed. The quantity of heat required for raising the temperature of one pound of water from 50° to 210°, which may be taken as maximum requirements, is 210 — 50 = 160 heat units. Therefore, only $\frac{160}{966}$, or approximately 1/6 of the heat in each pound of exhaust steam can be utilized in warming the pound of feed water which is to replace it in the boiler. Heaters using exhaust or live steam are divided into two kinds, known as open and closed heaters. When the waste gases from the furnace are employed the apparatus is commonly called an economizer. Open heaters usually consist of a chamber of cast iron or steel plate, into which the steam is admitted. Cold water is fed in at the top and in most forms is made to fall in thin sheets by flowing over shallow trays placed one below the other. The intimate contact of the water with the steam heats it to a temperature very nearly that of the steam. When the water contains scale-forming salts, which are precipitated at temperatures below that to which the water is heated, the sediment is caught by the trays and can be removed from time to time as required. Heaters of this form are sometimes provided with filters which still further purify the water before it is pumped to the boilers.

As the condensed steam is mixed with the feed water, it becomes necessary to pass it through an efficient oil separator before it enters the heater.

Fig. 1 shows a section through a Cochrane feed-water heater and purifier, which is of the type just described.

The cold water enters at the top and trickles downward over intercepting trays to the receiver at the bottom. When the water line in the receiver reaches a given

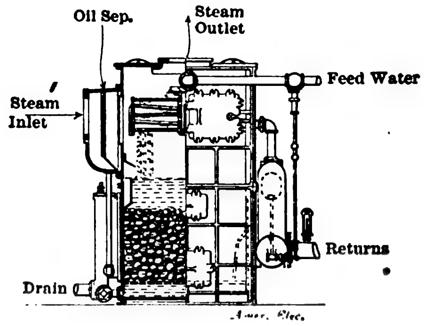

FIG. 1.—OPEN FEED-WATER HEATER.

point, a valve operated by a float closes the supply. Exhaust steam enters at the side through an oil separator and passes out at the top of the heater. The oil from the separator is trapped to the sewer.

When used in connection with a heating system the returns are brought back as shown. All drips from separators, steam jackets, etc., may be trapped into the receiver.

Before being pumped into the boilers

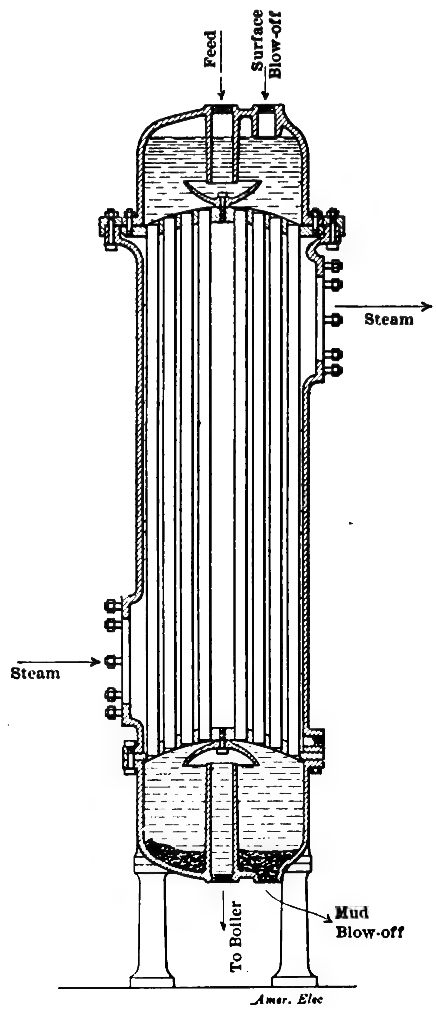

FIG. 2.—CLOSED FEED-WATER HEATER.

the water passes through a coke filter at the bottom of the receiving chamber.

With a closed heater the feed water does not mingle with the steam, but passes through a series of brass or copper tubes which are surrounded with steam on the outside. The Goubert heater shown in Fig. 2 is a good illustration of this type. Closed heaters are made for use in both vertical and horizontal positions, the former, however, on account of the small floor space required is usually preferable, unless it is desired to suspend it overhead. There are various forms of construction employed, some having straight tubes while in others the heating surface is in the form of a coil. When straight tubes are used one end is made to slide in a stuffing box or ground joint in the tube sheet in order to provide for the unequal expansion of the iron shell and the brass or copper tubes.

The required amount of heating surface depends upon the initial temperature of the feed water, the steam pressure within the heater and the velocity with which the water flows through the tubes. With exhaust steam from non-condensing engines it is customary to allow about one square foot of heating surface for each 90 pounds of water passed through the heater per hour. When the exhaust from condensing engines is used the surface should be increased about 50 per cent, owing to the lower temperature of the steam. This is equivalent to about 1/3 of a square foot of heating surface per boiler horse-power when non-condensing engines are used and 1/2 of a square foot for condensing engines.

The temperature to which the feed water may be raised usually varies from 200° to 210° with exhaust steam from non-condensing engines, and from 110° to 120° in the case of condensing engines. In many condensing plants the exhaust from the various pumps and other auxiliaries is sufficient to heat the feed water for the entire plant.

When the exhaust from these sources is equal to about 1/6 of the entire quantity of steam generated by the boilers, there will be nothing gained by placing a heater in the exhaust pipe leading to the condenser; but if the exhaust from the auxiliaries is less than this amount, then the feed water may be first passed through a heater supplied with steam at condenser pressure, and then through a second heater taking the pump exhaust at atmospheric pressure, which will heat the water up to a temperature of about 205°.

A HIGHLY EFFICIENT AND EASILY MADE WATER RHEOSTAT.

BY H. Y. HADEN.

Many engineers know the little troubles connected with rigging up a temporary water rheostat for taking up the load while testing engines. Barrels and plates are usually employed, and a very usual weakness lies in the boiling of the water, and the consequent rapid fluctuation of the load, which always depreciates the engine performance. It is also generally necessary to use salt in the water, and too much of this will put the rheostat out of control. In Fig. 1 is given a diagram of a rheostat in which galvanized iron wire, immersed in pure water, is used. The one in question ab-

sorbed a load of 100 kilowatts for nine hours continuously, with less than 1 per cent fluctuation, the final adjustment being obtained by controlling the inflow of circulating cold water, which simply overflowed the trough.

There were four coils used, which were all connected at one end to a copper rod. The other ends were each operated by switches, so that approximately 1/4, 1/2, 3/4 and full load could be obtained at will. Two of the coils were of No. 14 B. & S. gauge, 180 ft. long, and were made by winding on a 1 1/4-in. arbor. The remaining two were made of No. 16 B. & S. gauge and were 150 ft. long.

The receptacle in this case was a common horse drinking trough, and the coils

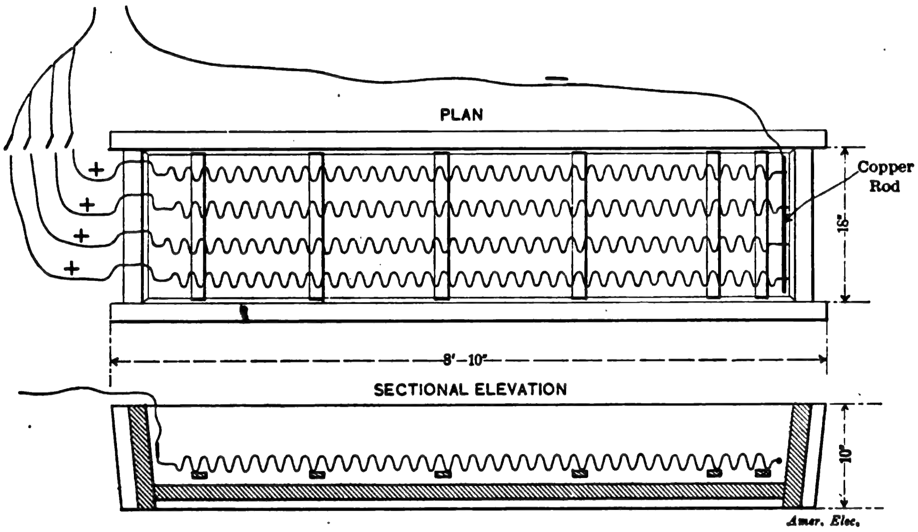

FIG. 1.—WATER RHEOSTAT.

were laid on a number of supporting cross-pieces. As there was a 3-in. clearance between each coil there was no tendency to touch. Accompanying this is a table giving the data concerning the carrying capacity of iron wire under water.

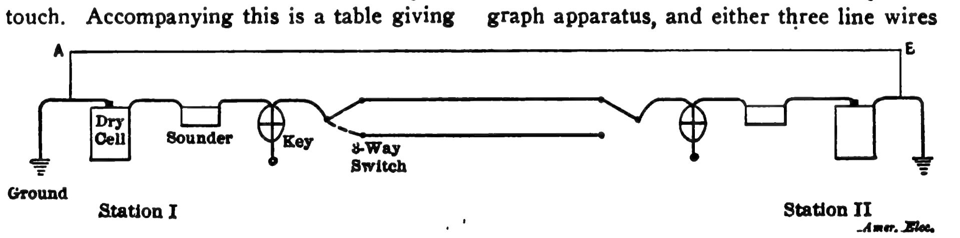
American Street and Interurban Railway Association.—At the 24th meeting of the American Street Railway Association, now known as above, held in Philadelphia, September 27 and 28. W. Caryl Ely was re-elected president.

Letters on Practical Subjects

Communications intended for publication in this department must be received at this office not later than the 15th of the month prior to the date of publication.

Telegraphing with Open Circuit Batteries.

I enclose herewith a sketch for a new arrangement of private or amateur telegraph outfit which might prove attractive to your readers, as it eliminates the obnoxious "crowfoot" cell. Little explanation is needed, as the diagram is almost self-explanatory. Two three-pole switches are connected as shown to the ordinary telegraph apparatus, and either three line wires



TELEGRAPHING WITH OPEN CIRCUIT BATTERIES.

or two line wires and a good ground return may be used. The operation of the key switch is the same in all cases. The three-way switches are shown in a position ready to operate. The dotted line of the switch at Station I shows the circuit open and not in use, while the line A B shows the third line wire or complete metallic circuit.

R. C. JACKSON.

Los Angeles, Cal.

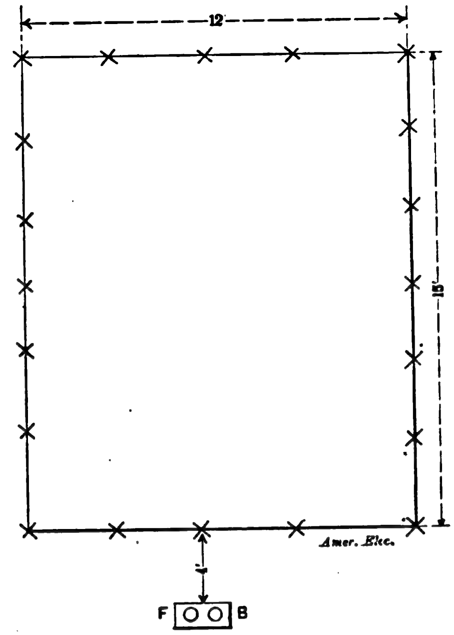
Information Wanted.

Can any of the readers of the AMERICAN ELECTRICIAN inform me how I can ring a 800-lb. fire bell continuously, or signal at a distance of 1000 feet from same without installing an expensive ringer? I have a 3/4-h.p. motor, and the current supply is 110 volts alternating current.

Gonzales, Tex. C. I. BOQUET.

Problem in Lamp Installation.

The sketch herewith shows a room 12 ft. by 15 ft. It is desired to wire this room for 20 incandescent lamps, as indicated. The



PROBLEM IN LAMP INSTALLATION.

lamps are to be placed on the walls near the ceiling, and the fuses are to be placed four feet below the line of the lamps. The available voltage is 220, but the lamps to be used are 110-volt, 4-c.p., screwed into ordinary open-wire Edison receptacles. The problem is to do the wiring with the least amount of material.

FRED MAHAFFEY.

Paris, Texas.

Alternating-Current Power Measurement.

Accompanying is a diagram of connections for three-phase power measurement as asked for by Mr. Lisberger in the August number. The scheme requires three wattmeters, together with current transformers and potential transformers. The potential transformers have a ratio of 10:1; that is, with a primary voltage of 2300 a secondary voltage of 230 is obtained. In the diagram the meters are connected up as three separate single-phase meters. A, B and C are the current transformers, the secondaries of which, SS, connect with the current coils of the meters; a, b and c are the potential transformers, the secondaries of which, SS, are connected to the pressure coils of the meters. If the dial constant of the meters be represented by K the constant for each meter will be 1,600 K, which is obtained by multiplying the ratio of the current transformer by the ratio of the potential transformer. The total output is the sum of the three meter readings times this constant. No change can easily be made if the meter constant is an awkward number, for to make the constant an even number, the gearing of the meter will have to be altered.

H. F. MUNSON.

Oakland, Cal.

In answer to Mr. Lisberger's inquiry regarding the measurement of three-phase power, I would suggest the arrangement shown by Fig. 2. An artificial neutral is produced, which without stepping down

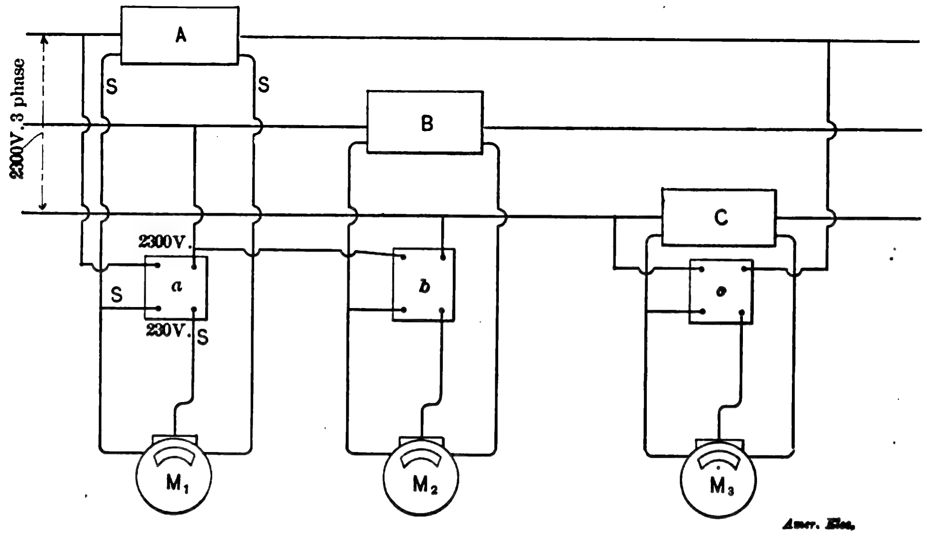


FIG. 1.—MR. MUNSON'S SOLUTION.

would give 1908 volts on the potential coils of the meter. As the meters are wound for

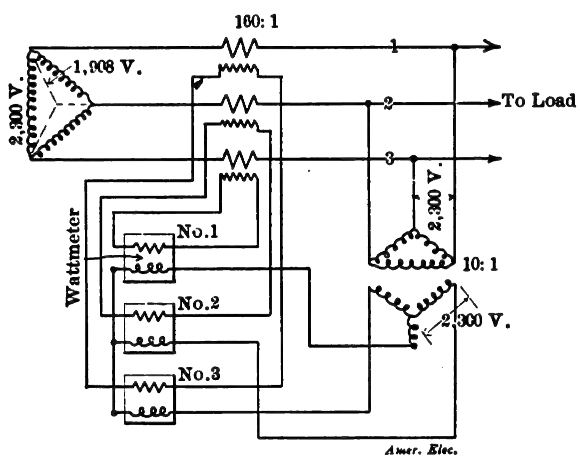

FIG. 2.—MR. UMSTEAD'S SOLUTION.

220 volts, it is necessary to step the voltage down as shown. The constant would then be $160 \times (10 \div \sqrt{3})$. A new scale could be figured out and pasted over the old scale in such a manner as to be easily removed when necessary.

Wilkinsburg, Pa. E. J. UMSTEAD.

To solve Mr. Lisberger's problem in alternating-current power measurement, only two wattmeters are required. These are connected as shown by Fig. 3. By the use of the series transformers the power is reduced to $\frac{1}{160}$th while the shunt transformer reduces the power to $\frac{1}{20}$th. Thus the power measured is $\frac{1}{160} \times \frac{1}{20} = \frac{1}{3200}$, the power actually taken by the receiver circuit. The constant is therefore 3,200, and the total power is equal to 3,200 times the sum of the wattmeter readings.

Elkhart, Ind. A. H. SWEETNAM.

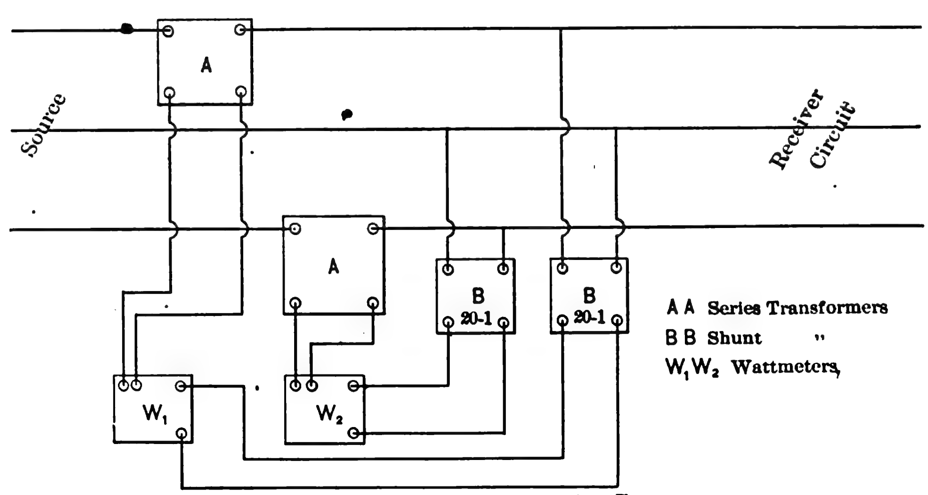

FIG. 3.—MR. SWEETNAM'S SOLUTION.

Mr. Gause's Problem in Bell Wiring.

Enclosed find a solution, Fig. 1, to Mr. Gause's problem in bell wiring published in the September number. By pressing the buttons on the first or third floors, the bell on the second floor will ring; by pressing the lower button on the second floor, the bell on the first floor will ring, and by pressing the top button on the second floor, the bell on the third floor will ring, as required in the problem.

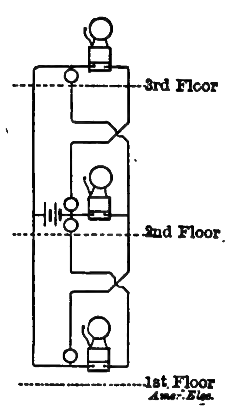

FIG. 1.

Chicago, Ill. A. NELSON.

The same solution was received from L. P. Brodie, Colton, Cal., and W. A. Neafii, Ossining, N. Y.

The accompanying diagram, Fig. 2, is offered as a solution of Mr. Gause's problem in bell wiring: Three 3-point and one two-point push buttons are used. By pushing the button on the first floor, the bell on the second floor rings, and by pressing the button on the third floor the bell on the second floor rings. By pressing the three-point button on the second floor, the bell on the first floor rings, and by pressing the two-point button the bell on the third floor rings.

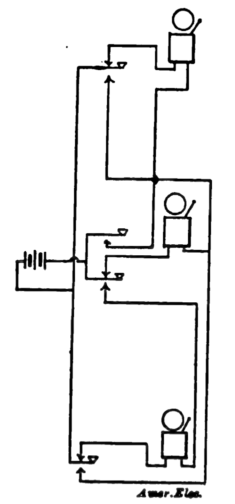

FIG. 2.

C. H. MORRISON.
San Mateo, Cal.

A somewhat similar solution was received from Harry I. Bayers, Jamaica Plain, Mass.

The accompanying diagram (Fig. 3) is offered as a solution of Mr. Gause's problem in bell wiring. The diagram is so plain that no explanation is necessary.

Philadelphia, Pa. CHARLES E. PYLE.

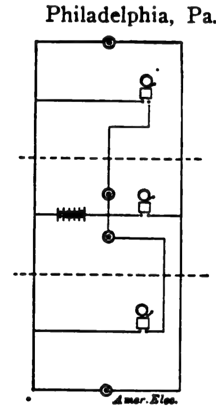

FIG. 3.

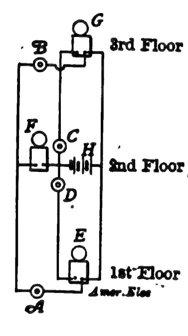

FIG. 4.

Similar solutions were received from Charles E. Bergborn, Fort Hamilton, N. Y.; F. S. Brewer, Newark, N. Y.; W. L. Diffendorf, Akron, Ohio; F. S. Driggs, Athens, Ohio; Clarence E. Faber, Williamsport, Pa.; W. G. Hanson, State Farm, Mass.; Emory E. Jones, Stanford, W. Va.; R. R.

Miller, Grand Rapids, Mich.; A. N. Voss, Milwaukee, Wis.

I would suggest the following as a method for accomplishing the ringing of the bells as per Mr. Gause's problem in the last number: The push button *A* (Fig. 4) rings the bell *F*, the push button *B* rings the bell *F*, the push button *C* rings the bell *G*,

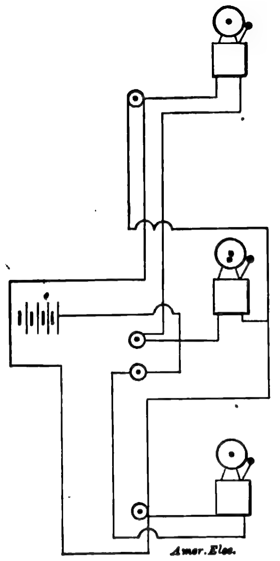

FIG. 5.

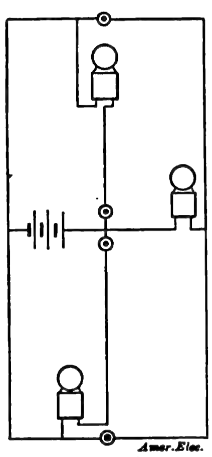

FIG. 6.

and the push button *D* rings the bell *E*.

Meadville, Pa. HARRY DAVENPORT.

Similar solutions were received from Charles Charest, Montreal, Canada; James B. Dillon, Louisville, Ky.; H. A. Fiske, Kingston, R. I.; J. A. Small, Toronto, Ont.

I submit the enclosed diagram (Fig. 5) as a solution of Mr. Gause's problem in bell wiring.

New York City. P. M. RAINEY.

This solution was also furnished by C. C. Coughlin, Rushville, Ind., and H. Painter, Philadelphia, Pa., and is identical with Mr. Gause's solution of his own problem.

The accompanying diagram (Fig. 6) is offered as a solution of Mr. Gause's problem in bell wiring.

Fort Wayne, Ind. K. F. H. FLOERRING.

Similar solutions were received from

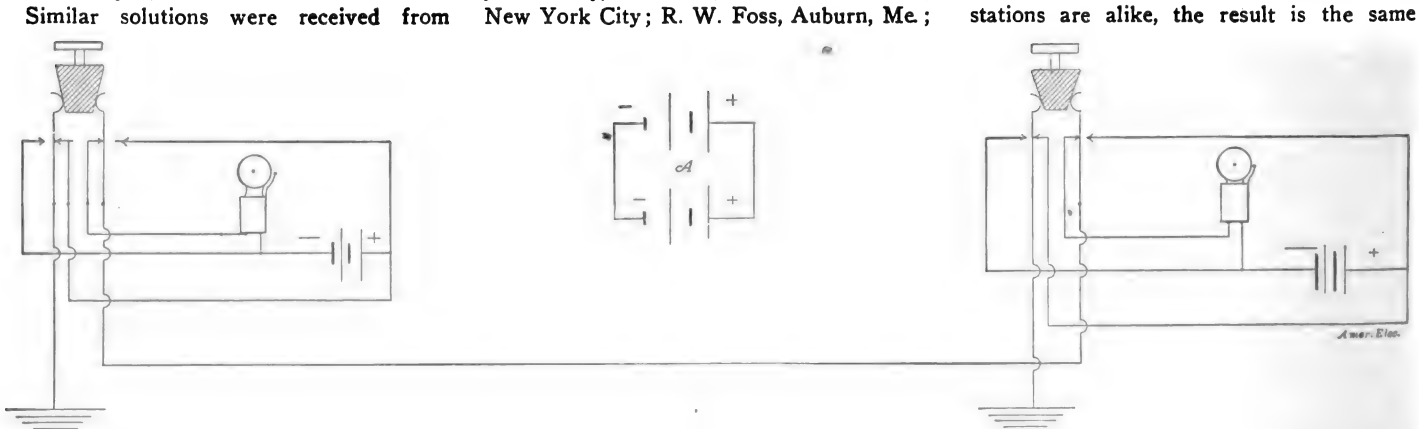

FIG. 3.—MR. BETHELL'S SOLUTION.

George Bates, Lynn, Mass.; W. O. Hendrickson, Argyle, Wis.; Percy Higginson, New York City; H. H. Kennedy, Indianapolis, Ind.; Morris Podell, New York City; Samuel Saeta, Philadelphia, Pa.; Nelson P. Weier, Flushing, L. I.; Alexander Weinberg, Zanesville, Ohio.

I enclose a diagram (Fig. 7) which I

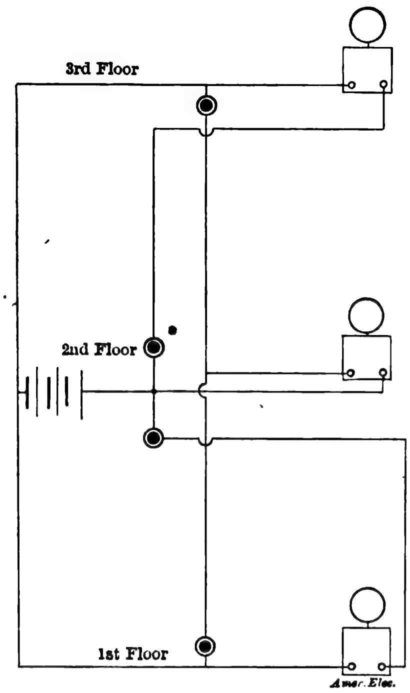

FIG. 7.

trust may be of interest as a solution of Mr. Gause's problem in bell wiring, appearing in the September issue.

New York City. SIDNEY DIAMANT.

Similar solutions were also received from

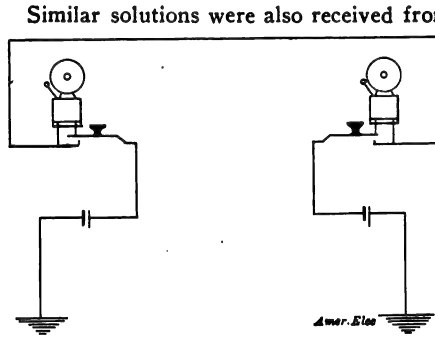

FIG. 1.—MR. HENDRICKSON'S SOLUTION.

J. H. Brady, Baltimore, Md.; Bernard Elias, New York City; R. W. Foss, Auburn, Me.; James H. Lacy, New York City; W. P. Robinson, Detroit, Mich.; Ernest Stevens, Dallas, Texas.

Enclosed herewith find a solution (Fig. 8) of Mr. Gause's problem in bell wiring.

Ft. Leavenworth, Kan. JUNIOR PARISH.

Similar solutions were received from N. P. Bethell, Washington, D. C.; J. A. Brown, Toms River, N. J.; T. A. Daryman, Allegheny, Pa.; A. L Denniston, Salt Lake City, Utah; D. C. McKeehan, Victor, Col.; Wil-

son A. McCown, Ladonia, Texas; P. C. Petersen, Fort Monroe, Va.

Mr. Riggs' Problem in Telephone Signalling.

I submit the following solution (Fig. 1) to Mr. Riggs' problem, which I think will answer his purpose. Pressing the key at one station rings the bell at the other sta-

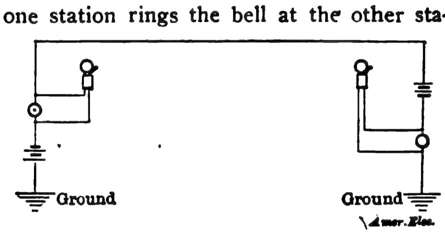

FIG. 2.—MR. KENNEDY'S SOLUTION.

tion. Both batteries are used and since both stations are alike, the result is the same from either end.

Argyle, Wis. W. O. HENDRICKSON.

Similar solutions were received from James S. Lacy, New York City, and Nelson P. Weier, Flushing, L. I.

I submit the following diagram (Fig. 2) as a solution of Mr. Riggs' problem in telephone signalling. A double-contact push button is used to cut out the bell at the station where the signal originates.

Indianapolis, Ind. H. H. Kennedy.

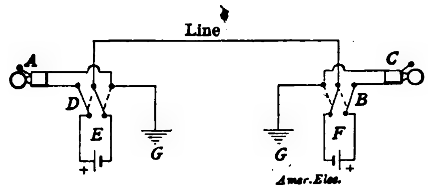

FIG. 4.—MR. RIGGS' SOLUTION.

I offer the accompanying solution (Fig. 3) as an answer to Mr. Riggs' problem in telephone signalling. With the buttons in their normal position, the batteries are connected, as shown at *A*, and when either button is depressed the batteries are thrown in series with the bell at the station being rung.

Washington, D. C. N. P. Bethell.

Similar solutions were received from James B. Dillon, Louisville, Ky., and C. H. Morrison, San Mateo, Cal.

The author's solution is shown in Fig. 4. The pushes, *D* and *B*, are pole changers, and were built in the form of buttons. The batteries are normally opposed, so that no current flows when the line is not in use.

Mr. Frederick's Problem in Telephone Lamp Connections.

The accompanying diagram (Fig. 1) is furnished as a solution to Mr. Frederick's problem in telephone lamp connections published in the September number. When a plug is inserted in jack *A*, springs *L* and *M* will be connected together, and the current flows from the positive side on the battery, through both lamps, *C* and *C*, in parallel, through the spring, *Y*, through the sleeve side of the line *Z*, to the negative end of the battery. When a plug is inserted in jack *B*, the same thing, of course, occurs. With both plugs out, connection with the positive side of the battery is broken, and with both plugs in, connection with the negative side of the battery is broken.

Chicago, Ill. Einar Brofos.

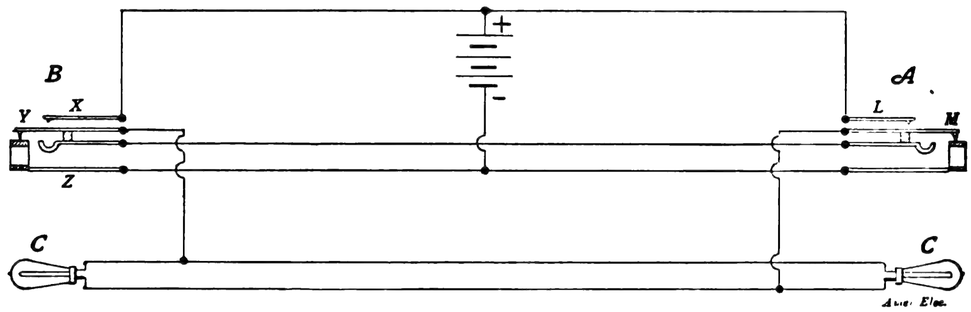

FIG. 1.—MR. BROFOS'S SOLUTION.

I submit the following solution (Fig. 2) to Mr. C. H. Frederick's problem in telephone lamp connections. The contacts of wires 2 and 4 are broken when the plug is inserted in the jack at either end, and the contacts of wires 1 and 2 are made at the same operation. I hardly think any further explanation necessary.

Washington, D. C. N. P. Bethell.

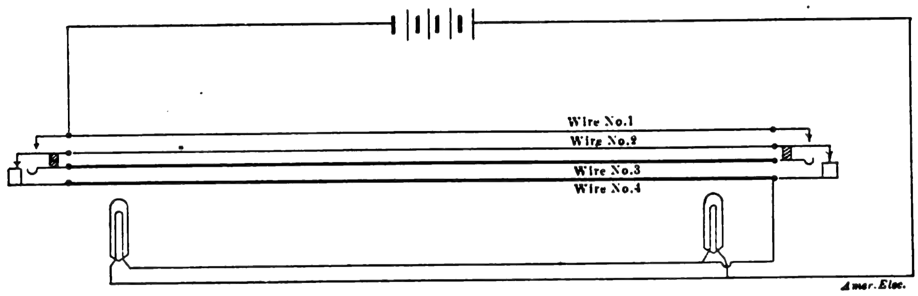

FIG. 2.—MR. BETHELL'S SOLUTION.

Enclosed please find a solution (Fig. 3) to Mr. Frederick's problem in telephone lamp connections. This scheme will work, provided there is no ground on the battery, and it is used as a single circuit.

Toronto, Ont. J. A. Small.

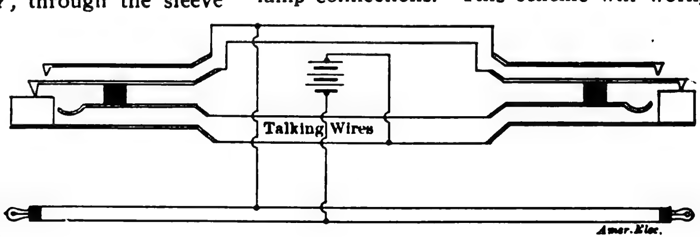

FIG. 3.—MR. SMALL'S SOLUTION.

The following diagram (Fig. 4) is submitted as a solution of Mr. Frederick's problem in telephone lamp connections. The diagram is self-explanatory.

Salt Lake City, Utah. A. L. Denniston.

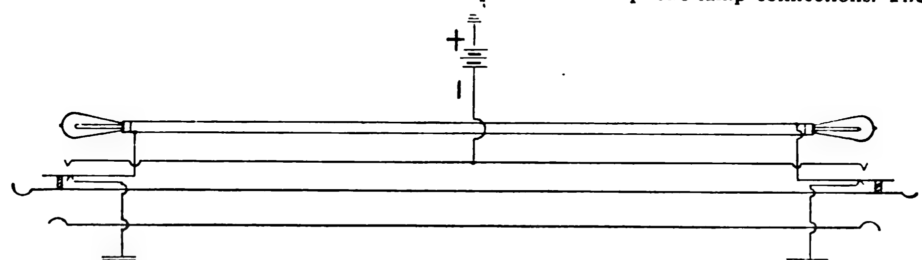

FIG. 4.—MR. DENNISTON'S SOLUTION.

The author's solution is shown in Fig. 5.

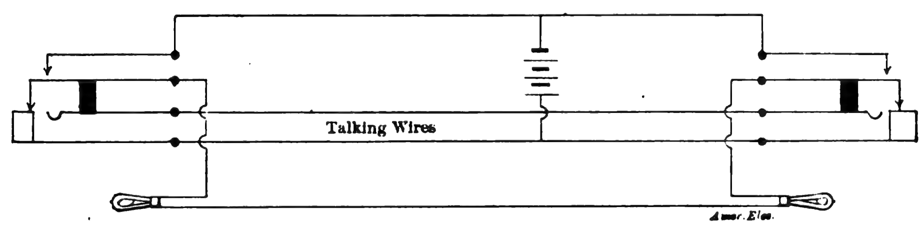

FIG. 5.—MR. FREDERICK'S SOLUTION.

Rise of Potential in Telephone Circuits.

Referring to the peculiar changes of potential in a pulsating ringing circuit, noted by Mr. Bethell in the September issue, I beg to offer the following explanation: It was stated that the e.m.f. of the ringing circuit, unloaded, was 40 volts; that when a 1,000-ohm ringer was operated through a 2-microfarad condenser the potential was 50 volts; and that when the ringer was operated without the condenser the potential would fall to 26 volts, the connections being shown in Fig. 1. I take it that the voltmeter used was a direct-current instrument, and that the pulsating current consisted of uni-directional pulsations alternated with dead periods approximately of the same time interval, and that the ringing lead during each dead period was first opened, then grounded and then opened again, these open

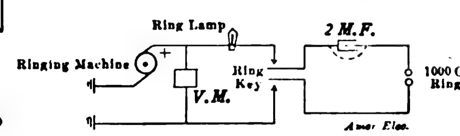

FIG. I.

portions corresponding to the rather large insulating segments separating the live and grounded segments of the commutator, Fig. 2. The direct-current voltmeter reading is an approach to an average potential value,

the needle trying to first go up, then down, then to remain at zero, etc. As the 1,000-ohm bell and its condenser are connected, each pulsation charges the condenser positively toward the positive side of the circuit, and at each of the first open portions

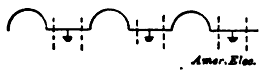

FIG. 2.

of the dead periods the charged condenser discharges back on the line, which sends the current through the voltmeter in a positive direction; so that the voltmeter now receives current pulsations during both current and dead periods, which raises the reading. When the condenser is short-circuited, the self-induction of the 1,000-ohm bell coils comes into play, and during the dead periods the discharge of the coils sends the current through the voltmeter in the opposite direction, causing a lowering of the reading. If an alternating-current voltmeter is placed in parallel with the direct-current voltmeter, then in the first case, when the direct-current voltmeter reads high the alternating-current voltmeter will also read higher than it did before the bell was operated, but in the second case, when the direct-current voltmeter drops, the alternating-current voltmeter will still read higher, since current through it in either direction affects the needle the same.

Thos. Addison Nathans.
Fordham, N. Y.

Referring to the problem submitted by Mr. N. P. Bethell, I would say that the rise in potential is due to the discharge of the condenser, the condenser being in series with the sources of e.m.f., so that the potential of this at discharge must be added to the potential of the ringing machine.

A. L. Denniston.
Salt Lake City, Utah.

I would suggest that the rise in potential on Mr. Bethell's telephone circuit was caused by a leading current. When the circuit is opened there is no drop through the armature of the generator, and the normal voltage is obtained. As soon as the condenser and bell are connected in the circuit, a leading current flows through the armature. The magnetism produced by this leading current reinforces the magnetism of the field magnet, hence the increase in voltage is greater than the drop through the armature. When the condenser is cut out a lagging current is produced and its magnetism weakens that of the field. This and the armature drop cause the voltage drop.

Granite, Ill. Harry C. Coates.

The result obtained by Mr. Bethell would seem to be about what one would expect. Throwing in the condenser causes a rise in voltage of the impulse wave, which is almost analogous to a wave of water striking a rock-bound shore, so that the voltage is higher with the condenser than without; or, in other words, the voltage is lower where the wave passes around the circuit unimpeded.

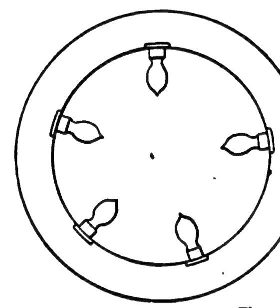
Grand Rapids, Mich. R. R. Miller.

Diversified Power Plant Experience.

Having obtained much helpful information through the Letters Department of your valuable paper, leads me to believe that a leaf or two from my own diary of experience might be the means of helping some one else out of some of the close corners in which all engineers during the course of their lives find themselves. Not many years ago I was employed in a steam plant having three units, two of 250 horse-power and one of 1000 horse-power; the former driving 200-kw. generators and the latter a 700-kw. machine. All the units were in operation during the period of heavy load, and as the load dropped off one of the small units was cut out, then the large unit, and finally the other small unit. This caused one of the small units to be the first to be cut in service and the last to be switched out. When starting up the first small unit one morning, the machine, to our surprise, built up to 50 volts, but would go no higher; the line voltage was 600. Every part of the generator was carefully gone over and it seemed all right, so the engine was stopped for the purpose of making a closer inspection. One of the assistants by chance caught hold of one of the shunt field connections, and the wire pulled out of the coupling very easily. On examination it was found that the screw holding it in place had backed out far enough to let the wire just touch and form a very poor contact. After tightening up the screw the machine was put in operation again and built up quickly.

While employed in another plant, I had a like experience with a machine which would not build up; but the trouble was found in a different place. This particular machine was the last to be shut down at night and the second to be cut in on the line in the morning, and it would not build up at all. From my previous experience I surmised that the trouble might be in the field and brush connections; but upon examination nothing was found wrong. I came to the conclusion then that the trouble must be on the feeder board where the machine switches and rheostat were located. On making a hasty examination nothing appeared wrong; but on looking at the rheostat on the back of the board I noticed a thick scum on the segments. I took a piece of sandpaper and cleaned the shoe and segments and then gave the machine another trial. This time it built up without any trouble, and I made up my mind that after that the rheostat needed attention as well as the other apparatus and would be inspected regularly. I think that while the rheostat was warm the shoe made contact; but when it got cold after shutting down the scum acted as an insulator.

At another place where I was in charge the factory was equipped with motors and the current was furnished by the local light and power company. An assistant was detailed to look after the motors and shafting and one morning he reported that one of the motors refused to start. I made an examination of all the connections and could find no reason why the machine should not run when current was applied. I asked the assistant what he had done prior to shutting down the night before, and he informed me that he had wiped the commutator as usual, using a clean piece of cloth, as the old piece was dirty. On examining the cloth I quickly found what the trouble was. In a sheet-iron cabinet we kept paint, oil and shellac together, with some clean oil for wetting the cloth to wipe the commutator with. It happened that on the day in question some one had used the shellac and placed it where the oil was usually kept. The tender in his hurry to shut down and get out did not notice the difference, and wet his cloth with shellac instead of oil. This he applied to the commutator after the current had been turned off, and it naturally formed a good insulator between the commutator and the



HOME-MADE REFLECTOR.

brushes. The main belt was thrown off and the armature turned by hand while a piece of sandpaper was held against the commutator. After thoroughly cleaning the commutator the belt was replaced, current turned on, and the motor ran as smoothly as ever.

Some of your readers may have at some time or other the hard luck of having a superintendent who sticks to old ways, regardless of the time and worry it costs the engineer. This was my lot in the plant first mentioned. There was a small blacksmith shop where most of our repair work was done, such as bushing or babbitting pulleys; in fact, we gave out very little of our repair work. This shop was located in a dark corner of the factory and the only light obtainable was from five 16-c.p., 110-volt lamps. I had repeatedly asked for reflectors to put on the lamps, and although the cost of these was small they were not forthcoming. I made up my mind after waiting some time to make one, and to rearrange the wiring so that I could form a cluster of the lights and arrange them so that they could be moved to any part of the room and lowered or raised to suit the work by means of a cord. I took a tin pan about 20 inches in diameter and cut a ½-in. board to the radius of the bottom of the pan and fastened this to the outside of it. I fastened blocks of wood on the inside, as shown by the sketch herewith, to fasten the sockets to, and cut a hole through the bottom of the pan to allow the wires to pass through. This worked satisfactorily and gave a good light for a long time until I finally got a reflector.

W. A. Dow.
Cambridge, Mass.

Questions and Answers

Inquiries not accompanied by the name and address of the inquirer, will not receive attention.

Is it practicable to operate a 500-volt 100-kw. generator connected to the outside wires of a three-wire circuit which is already being supplied by four 250-volt generators of smaller size, taking care of the unbalancing by means of the smaller machines? C. S. B.

Yes.

Please give instructions for changing a small single-phase induction motor, built for 104 volts and 125 cycles, so that it will operate on a 60-cycle circuit of the same voltage. J. M. E.

It is not practicable to make the change with satisfactory results.

If a person thoroughly insulated from the earth should take hold of a high-potential line, would he feel any sensation when his body became charged electrostatically? D. M.

Not unless he was sufficiently near to the earth to permit a discharge to pass from him to it.

What is the magnetic density usually employed in the air-gap of a 25-cycle induction motor? (2) Would a 25-cycle induction motor be larger than a 60-cycle machine of the same type? T. B.

From 40,000 to 60,00 magnetic lines of force per square inch, according to the type of design. (2) Yes.

Will two induction motors work well together belted to the same shaft? G. E. M.

Yes, provided the pulley ratios are properly proportioned and the machines have the same characteristic so that the relation between their speeds will remain constant at all loads.

Why is the distinctness of speech on a telephone circuit impaired when the wires are put in long cables? R. W. F.

Because the telephone wire and the sheath of the cable act as a condenser which absorbs a great deal of the effectiveness of the fluctuating current, thereby reducing the current available for the operation of the telephone receiver.

Which will pass more current, a single 110-volt lamp or two 110-volt lamps in series, the lamps being of the same type in both cases and the terminal voltage being the same? (2) Why is iron used for collector rings of revolving-field alternators instead of copper? H. W. F.

The single lamp will take more than twice the current that two similar lamps in series will take connected to the same circuit. (2) Because it is cheaper and more durable.

Please give data for an induction coil to give a 6-in. spark for wireless telegraph purposes. E. D. S.

Core, 1¼ ins. diameter by 12 ins. long, built up of No. 22 annealed iron wires; primary winding, two layers of No. 12 wire; secondary winding, 7 pounds of No. 36 wire; divide the secondary into at least four sections and preferably six. Put 60 sheets of tinfoil, each 6 ins. x 10 ins. in size, in the condenser.

How can the voltage and output capacity of a generator be ascertained without testing the machine when it has no name-plate? E. J. B.

It is impossible to make such a determination with any approach to accuracy. The output capacity in amperes may be roughly estimated by adding up the brush face contact areas and multiplying the sum of these by 20. It is practically impossible to estimate the voltage without a thorough knowledge of the armature winding, or without testing the machine at a rational speed.

Is it impossible to parallel single-phase alternators, and if so, why? (2) If it is possible to operate single-phase machines in parallel, what is the objection to doing so? (3) What is the approximate difference in size between a single-phase machine and a polyphase machine of the same rated output and speed? J. M. D.

Not if the machines are of modern design. (2) There is no objection except the inconvenience of throwing the machines into circuit in parallel. (3) There is not even an approximate ratio which holds good throughout any considerable range of sizes, and the ratio for any given size depends almost entirely upon the character of the design. It is easier to compare outputs for a given size of frame; a given frame with a polyphase winding will yield from 10 per cent to 30 per cent more output than with a single-phase winding of the same general type.

How is the resistance of a dynamo armature measured? (2) What horse-power is required to drive a dynamo delivering 630 amperes at 118 volts with an efficiency of 91 per cent.? (3) What is meant by an alternating current having a frequency of 60 cycles? (4) What is meant by the statement that a storage cell has a capacity of 1,000 ampere-hours? F. W. M.

The simplest and most reliable method is to pass current through the armature while it is standing stationary, regulating the current flow by means of an external adjustable resistance so as to keep the current well below the maximum capacity of the armature. Then measure the current and measure the voltage at the brushes simultaneously. Dividing the voltage by the current gives the resistance in ohms. (2) The output is $118 \times 630 = 74{,}340$ watts, which is equivalent to 99.65 horse-power. The efficiency being 91 per cent., the applied horse-power is equal to $99.65 \div 0.91 = 109.5$ horse-power. (3) A current which changes from positive to negative and back again sixty times in one second. (4) It usually means that if the cell is charged at its normal rate, when the charging current multiplied by the number of hours equals 1,000 it will be fully charged.

What is meant by the "pitch" of an armature winding? (2) Why are inductor alternators considered inferior to the usual type? J. L. W.

There are several "pitches" in an armature winding, none of which is it in the least necessary to consider. The front pitch is the number of steps, reckoned in armature conductors, from a given active conductor to the active conductor to which it is connected at the commutator segment; the back pitch is the number of steps from a given active conductor to the other active conductor of the same loop or coil to which it is directly connected across the back of the core. The commutator pitch is the true guide to the winding; it is the number of steps, reckoned in commutator bars, from one terminal of a coil to the other, after the coil is connected up. Thus, in a simple lap winding where the two terminals of each coil go to adjacent commutator bars, the commutator pitch is 1; in a wave-connected winding having 8 bars between the two to which the terminals of one coil are connected, the commutator pitch is 9. (2) Because of their poorer regulation.

What is the effect of lifting one or two sets of brushes on a six-pole dynamo carrying a light load? (2) What is the effect on a multipolar dynamo having one or two air-gaps larger than the others? (3) I have considerable trouble with grounds in conduit wiring supplying current to electric dumb waiters. The circuit is sometimes opened while a machine is at full speed, thereby stopping it suddenly. Would this cause grounds? I. H. K.

The effect would depend on the type of armature winding employed; if it is a wave winding, no harm would be done by lifting some of the brushes while carrying a light load. If it is a simple lap winding, no harm would be done unless the load actually carried was a greater proportion of the full load than the proportion of the total number of brushes remaining in service. (2) The magnetic pull on the armature becomes unbalanced, increasing the journal friction and wear, unless it happens that there is an even number of excessive air-gaps, and these are diametrically opposite each other in pairs. If the armature is lap-wound, without any equalizer connections, differences in air-gaps will cause local currents to flow in the winding and overheat it. (3) If the connections are such that opening the supply circuit will not allow the shunt fields of the motors to discharge through a closed path, the field discharge may puncture the insulation and cause the grounding.

What is a time relay? (2) What is an I. R. T. regulator and what is it used for? (3) Why are I. R. T. regulators not used in railway practice? (4) What causes high and low bars in a commutator? (5) What causes commutator bars to show a slight dark mark, irregular in shape, at the back end, close to the mica? (6) Can the speed of a rotary converter be varied by adjusting its shunt field excitation? (7) Why are motor balancers used in some of the Edison sub-stations instead of carrying the neutral conductor of the direct-current distribution to the middle point of the secondary windings of the transformers? W. H. S.

See Mr. Fernandez' article in the September number. (2) A three-phase regulating transformer, the primary of which is adjustable with relation to the secondary so as to vary the secondary voltage or even reverse it with respect to that of the circuit. It is used for adjusting the pressure on individual feeders supplied from a common set of bus-bars; also to regulate the voltage delivered to rotary converters and thereby regulate the direct-current delivered by the converters. (3) It is used in railway practice in the manner just stated. (4) The drying out of the insulating material between the bars and at the ends of the commutator. (5) Imperfect commutation; it is impossible to give the cause of the bad commutation without knowing all of the local conditions. (6) No. (7) Because closer regulation is obtainable by means of motor balancers.

NEW FT. WAYNE SERIES ALTERNATING ARC LIGHTING SYSTEM.

The Fort Wayne Electric Works, Fort Wayne, Ind., has developed a complete system for series arc lighting circuits to be operated from a constant-potential supply. The system consists broadly of a regulator for maintaining constant current, a specially designed high-tension switchboard, a constant-potential transformer and the series

FIG. 1.—REGULATOR FOR SERIES ALTERNATING-CURRENT SYSTEM OF ARC LIGHTING.

arc lamps. Both sides of the line are equipped with lightning arresters especially adapted to circuits of this nature.

Fig. 1 represents the regulator which has been designed for this system. Its operating principle is the familiar one of the automatic introduction of impedance into the lamp circuit whenever any decrease in the resistance of the latter would tend to cause an excessive current to flow therein. In details, however, the system differs from previous ones. The impedance is introduced by the combined movements of a laminated iron core and an impedance coil into such positions as to cause a greater magnetic flux to be cut by the conductor in the coil when the current is excessive; this, of course, produces a choking effect, reducing the current to its normal value. If for any reason the line current be decreased, the opposite action takes place and the current is automatically increased to its normal value. The mechanical parts of the regulator are said to be so arranged that the motion of the heavy core is small as compared with that of the coil, reducing the effect of inertia in the parts and giving more sensitive regulation. The core and the coils counterbalance each other, obviating the use of counter-weights. No attention is required at the regulator, the starting operation being entirely controlled from the switchboard specially designed for this purpose.

The switchboard consists of a single panel of blue Vermont marble, equipped with an ammeter, a reactance coil, fuses, and all necessary switches for the starting and control of the system. It can be furnished with or without a wattmeter sub-base equipped with an integrating wattmeter. The diagram, Fig. 2, shows the arrangement of circuits, etc., by means of which the system may be quickly put into operation from the switchboard. It is claimed that the system may be started up without causing any disturbance on the supply line. The starting switch, which is located in the center of the panel, should always be closed last. In the closing of this switch, three distinct conditions are produced. First, the reactance, which is mounted upon the back of the switchboard, is introduced into the regulator circuit, so that no rush of current will take place when the regulator is thrown upon the line. Next, the switch short-circuits the reactance, thus throwing the regulator, which has by that time reached its full load position, directly across the constant-potential bus-bars. During both of these operations the line leading to the arc lamps is short-circuited; when the starting switch is entirely closed, the short-circuit across the line is removed, putting the arc lamp system in normal operation. By thus connecting the lamps into the circuit after normal current has been established no disturbance is caused in the mechanism of the lamps.

Although the systems for 12 and 25 lights will operate satisfactorily without the use of a constant-potential transformer upon circuits of 1100 and 2200 volts respectively, it is advisable to use a transformer in all cases, even though it be of one-to-one ratio, merely for insulation purposes. This is especially desirable where both arc and incandescent systems are operated from one set of bus-bars, in order to insulate the arc system completely from that which supplies the incandescent lamps.

FIG. 3.—CONSTANT-POTENTIAL TRANSFORMER.

Fig. 3 represents a constant-potential transformer for use with this system; it may be either step-up or step-down, or it may maintain the same voltage upon the secondary that is supplied at its primary terminals in cases where it is introduced for insulation purposes only. The secondary of the transformer is provided with a number of taps, by the use of which the output may be varied as more or fewer arc

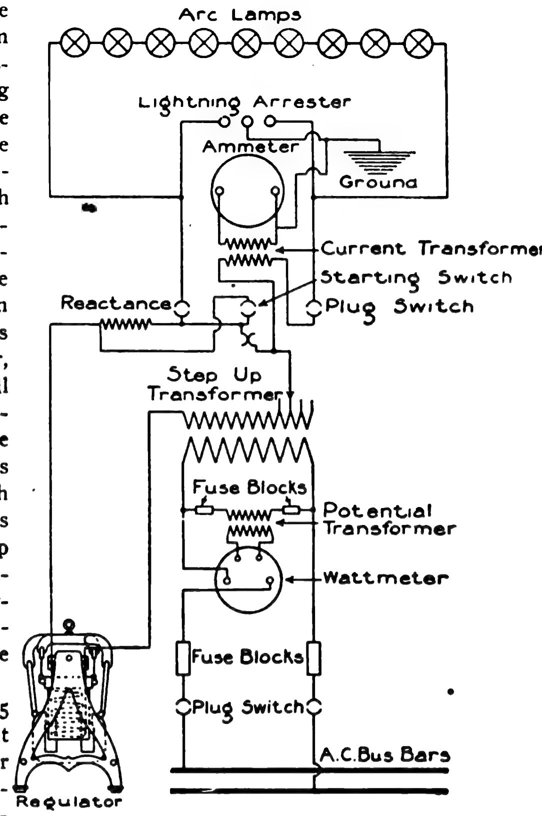


FIG. 2.—DIAGRAM OF CONNECTIONS FOR SERIES ALTERNATING-CURRENT SYSTEM OF ARC LIGHTING.

lamps are operated on the circuit, thereby maintaining a close approximation to full-load efficiency and power factor under the most unfavorable conditions.

The arc lamps which have been designed to operate in connection with this system conform to the high standard of the Fort Wayne direct-current lamps. They will operate at extremely low temperatures for 125 hours with one trimming, when adjusted for the normal current of 6.6 amperes. In the design of these lamps great care has been taken to prevent vibration and the consequent hum which frequently occurs in lamps operated on alternating-current circuits.

The system has been designed for either 60 or 140 cycles. The 140-cycle lamp has been especially designed for high-frequency service and cannot be operated on a 60-cycle circuit. Although the use of the 60-cycle system is advised wherever possible, owing to the fact that it is at present the tendency of central stations to reduce the frequency of their systems, the high-frequency lamp has been perfected in order that central station managers who already have 140-cycle circuits in use may be enabled to use this system.

New Apparatus and Appliances

STEEL-FRAME MULTIPOLAR BELTED MOTOR.

The, accompanying engravings illustrate a new line of steel-frame multipolar motors brought out by the Triumph Electric Com-

FIG. 1.—35-H.P. TRIUMPH MOTOR.

pany, of Cincinnati, Ohio. These motors are made either shunt, compound, or series wound, according to the service for which they are intended. They are adapted equally well to operate line shafts, machine tools, printing presses, laundry machinery, cranes, hoists, elevators, pumps, fans, or in fact, any sort of apparatus. The frame is made of close-grained steel, resulting in a very compact machine, and the brackets are centered against the crown and firmly held in place by steel bolts. The poles are also of steel and equipped with a special design of laminated shoe to provide the necessary magnetic fringe. This is said to result in sparkless operation, cool running and high efficiency. The bearings, which are of special bearing metal, are of the self-oiling, self-aligning type; they are made to gauge and reamed so as to be interchangeable and easily replaced. Oil wells of ample capacity

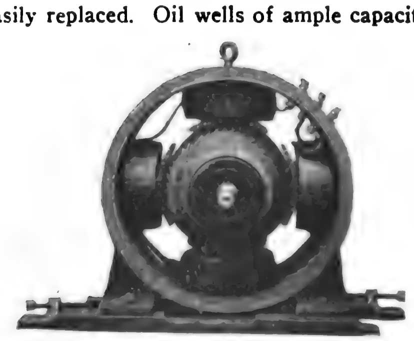

FIG. 2.—MOTOR WITH END PLATE REMOVED.

are provided in each pedestal. The armature is of the iron-clad laminated-core tooth type. The laminated discs are annealed and japanned after being punched and are then mounted and keyed directly on the shaft. The armature coils are form-wound and each consists of a continuous length of copper with no joint except where connected with the commutator. Each coil is insulated and tested before being placed in position, and alternate layers of heavy fuller board, mica and oiled linen are provided in the slots as additional insulation. The commutator is made up of drop-forged copper, the bars having great depth. The bars are mounted upon a cast-steel shell of such construction that it is said to be impossible

FIG. 3.—ARMATURE OF 10-H.P. MOTOR.

for them to move or for the commutator to get out of true. The bars are insulated from this shell and from one another by mica. With a view to making the machine as compact as possible, both ends of the armature are so arranged that the pedestals may project under them. An improved oil guard is provided, which it is claimed, makes it impossible for any oil from the bearings to enter the armature or commutator. The fields are all form-wound, thoroughly baked and insulated with fuller

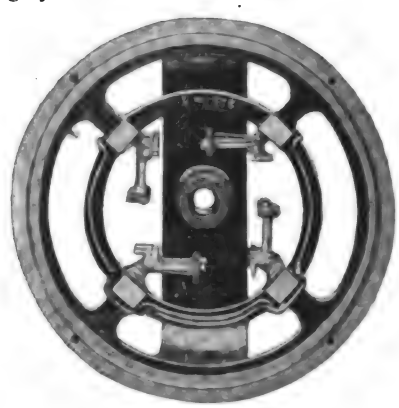

FIG. 4.—COMMUTATOR BEARING SHOWING BRUSH RIGGING.

board, mica, canvas and insulating varnish. During construction and after being placed in the machine, each coil is tested with 2,000-volt alternating-current. The brush-holders are of simple yet effective design. Carbon brushes are used, and these are rigidly attached to the holder, proper adjustment being secured by a tension spring. The brush rigging is carried over the front end of the crown instead of on the pedestal. The holders are convenient of access, and the yoke, when properly set, is held in position by a lock screw. The motors are said to be capable of withstanding heavy overloads and sudden fluctuations of load. They

FIG. 5.—MOTOR WITH IDLER ATTACHMENT.

can be readily arranged for either floor, wall or ceiling use, and their compact form and light weight permit them to be mounted directly upon the machine to be driven. With short belt drive the motor can be placed on very short centers, a flexible idler being provided, as shown in Fig. 5, which increases the belt surface on the pulley and overcomes the slackness of the belt.

NEW 500-VOLT RECEPTACLE.

Figs. 6 and 7 show two new receptacles brought out by P. H. Fielding, of Trenton, N. J. The design does away with the necessity of soldering and taping the lugs and also provides additional insulation, so that short-circuits in the receptacle are hardly possible. The manufacturer calls attention to the following points of merit:

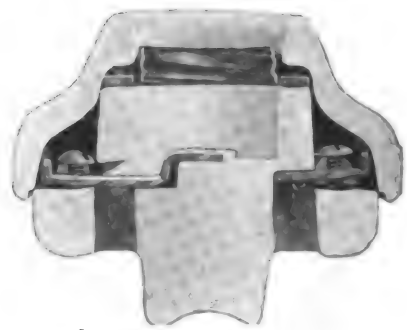

FIG. 6.—500-VOLT LAMP RECEPTACLE.

Flange on copper screw shell makes it very strong; No. 16 B. & S. washer held by three No. 4 screws on top of the flange of the shell makes it rigid; separation between shell and center contact is over ½ inch; the porcelain cap covering the binding screws also covers the top of the lamp base; the cap is held in place by two screws and there is no porcelain ring to break; the wires are kept a proper distance from the surface by the porcelain extension; the screws fast-

FIG. 7.—RECEPTACLE FOR OUTDOOR USE.

ening the receptacle are over an inch distant from any live wire; an air space between the receptacle and surface is provided to dry up any moisture; considerable time is saved in installing the receptacle. The engravings show the construction very well.

IMPROVED CARBON BRUSH CONNECTION.

The National Carbon Company, of Cleveland, Ohio, has brought out an expansion connection for carbon brushes for which many advantages are claimed. A carbon brush, of any size, has a hole drilled into it, penetrating about one-half of the brush. A piece of plaited flexible wire, terminating in a cable shoe, is unraveled at the end opposite to the cable shoe, and this miniature wire net is formed cylindrically around a little brass sleeve. This

sleeve is of the same length as the hole in the carbon brush, and is slotted over two-thirds of its length. The slot is tapped so that the closing screw fitting into the slot is forced into a tapering hole. The resistance with which the screw meets on account of this tapering is overcome by the sleeve expanding so that the whole appliance acts as a wedge when the screw is inserted, making a very close and rigid contact between the flexible wire and the interior of the brush, which is even increased through expansion of the metallic parts, should the brush become slightly heated while in use. This flexible connection is very easily detached and can be connected to a new brush simply by use of a screw driver, obviating the necessity of attaching by means of the soldering process. This connection is so arranged that the distance between the commutator surface and the terminal connection is reduced to a minimum, thereby reducing the carbon resistance between these points, resulting in obtaining a higher efficiency and a lower loss between the commutator surface and the end of the connection.

THE MABBS ELECTRIC ELEVATOR.

An elevator, which is a radical departure from previous electric elevators, has been designed by John W. Mabbs, of Chicago, Ill., and is shown by Fig. 8 herewith. The essential feature of the Mabbs elevator is that the motor forms the counter-weight and travels up and down a counter-weight shaft instead of being located permanently in the basement. The motor and other mechanism which form the counter-weight, however, differ from the ordinary counter-weight in that instead of depending on the cable altogether for support, the motors are geared to a vertical rack, so that it has at all times a positive mechanical connection with the sides of the shaft. The counter-weight is, therefore, raised and lowered by means of the motors operating on this rack and pinion. The motor, which is of a special design, has a vertical shaft and is geared through a worm gear to two horizontal shafts. Each horizontal shaft has a pinion on each end, making in all four pinions, which engage in four vertical racks. The racks are mounted upon the outer faces of two cast-iron columns. The motor mechanism hangs from a sheave around which the cables pass, as shown in Fig. 8. By this arrangement the elevator car, of course, travels two feet to each foot of motor travel. The motor hatchway, therefore, extends half the height of the building. The motor machine runs in guides on the inner faces of the cast-iron columns. Current is carried to the motor through copper-lined channel irons, mounted on porcelain block insulators situated on the columns between the motor guides and the racks.

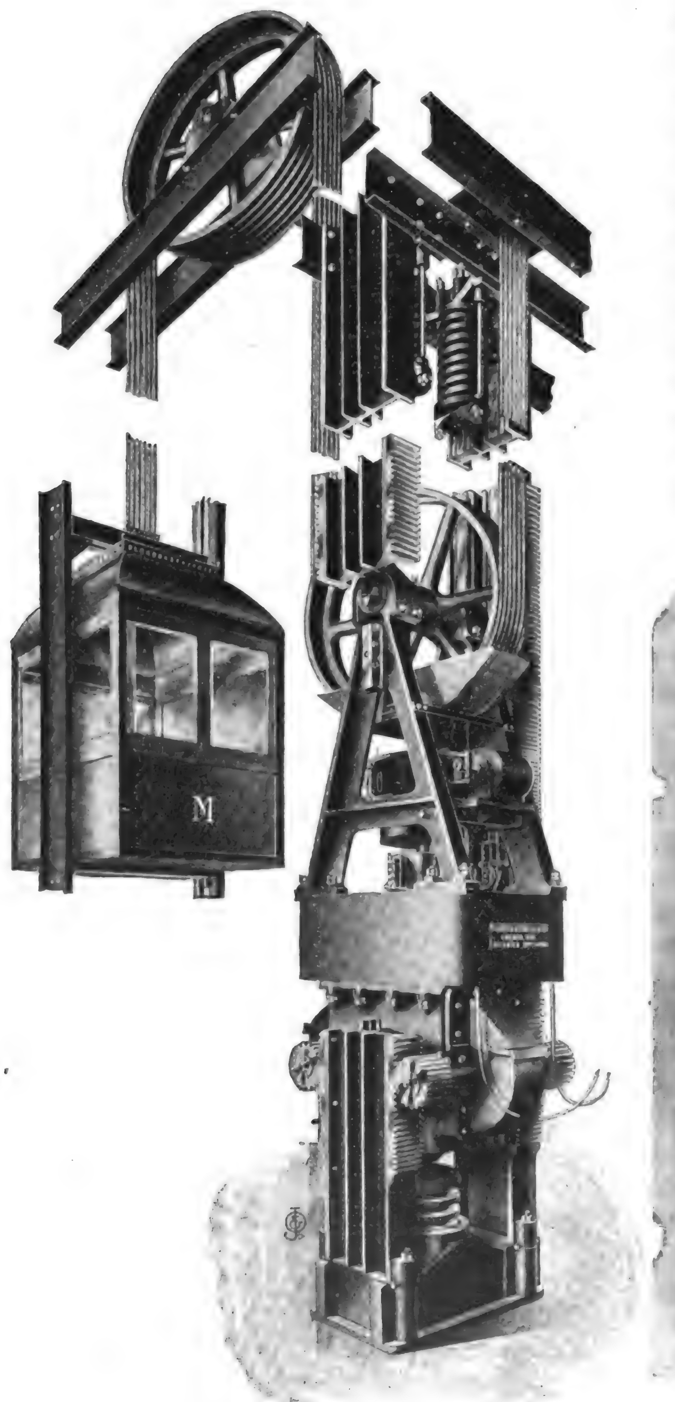

FIG. 8.—MABBS ELECTRIC ELEVATOR.

"UNIT" TYPE OF OIL FILTER.

Fig. 9 herewith shows a sectional view of the "Unit" type of American oil filter built by The Burt Manufacturing Company, of Akron, Ohio. In operation the dirty oil enters the waste oil receptacle and passes through small perforations, flowing thence horizontally to two filtering cylinders. In passing to the cylinders the heavy impurities fall into the sediment pan and therefore do not clog up the filtering cloths of filtering material. Each cylinder is wrapped with a cloth through which the oil must pass before entering. After passing through a quantity of bone black, the oil flows through two tubes in the bottom of the filter. By means of plates attached to the bottom of the tubes, the oil is spread out in a thin film and is washed by the water, so that any remaining impurities in

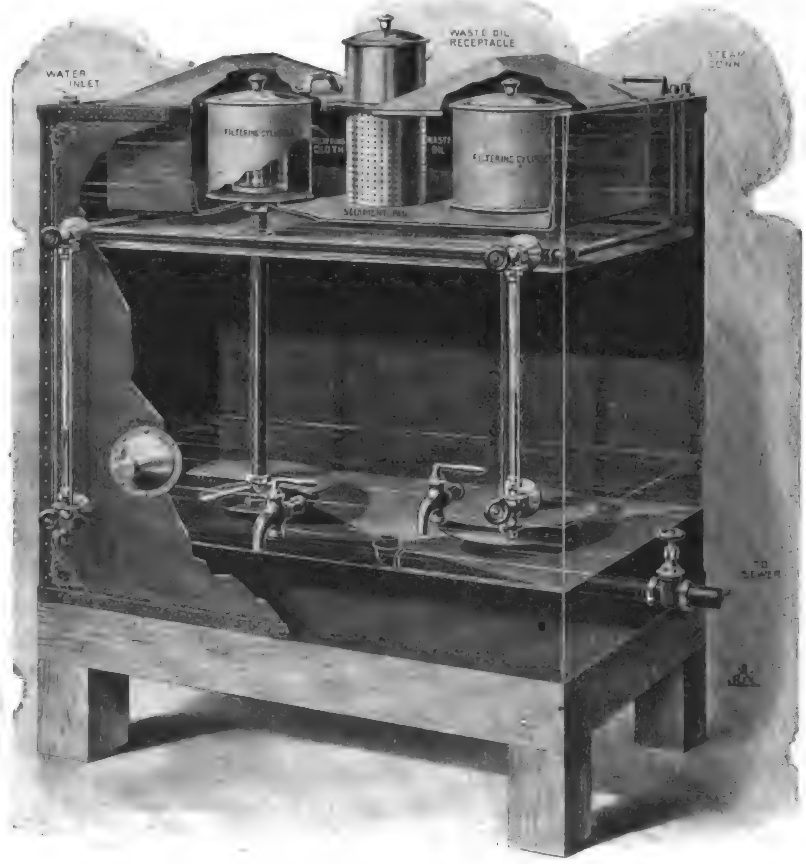

FIG. 9.—"UNIT" TYPE OIL FILTER.

the oil tend to drop to the bottom of the filter, where they may be flushed out by opening a gate valve connecting with the sewer. The manufacturer calls special attention to the hot water chamber in the upper part of the filter. This feature is covered by patents. The object in heating the oil before filtering is to render it more fluid and thus increase the speed of filtration. The filter is guaranteed to handle the heaviest grades of oil.

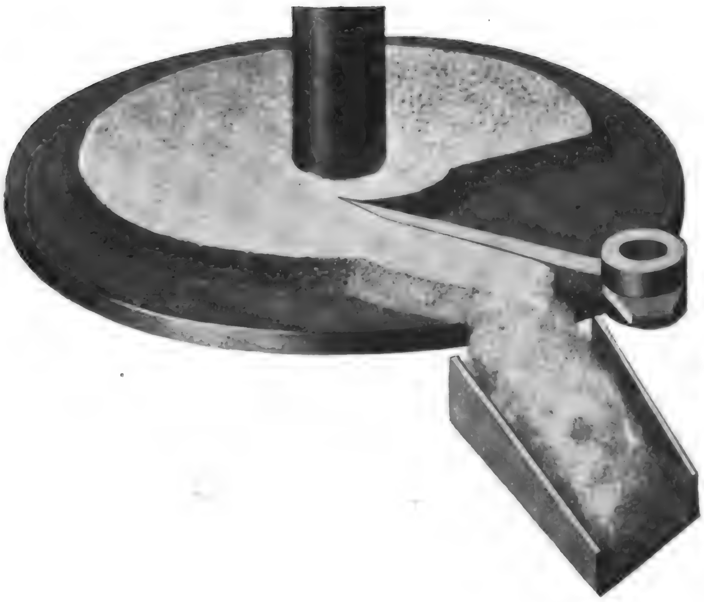

FIG. 10.—MECHANISM FOR INSURING REGULARITY OF DISCHARGE.

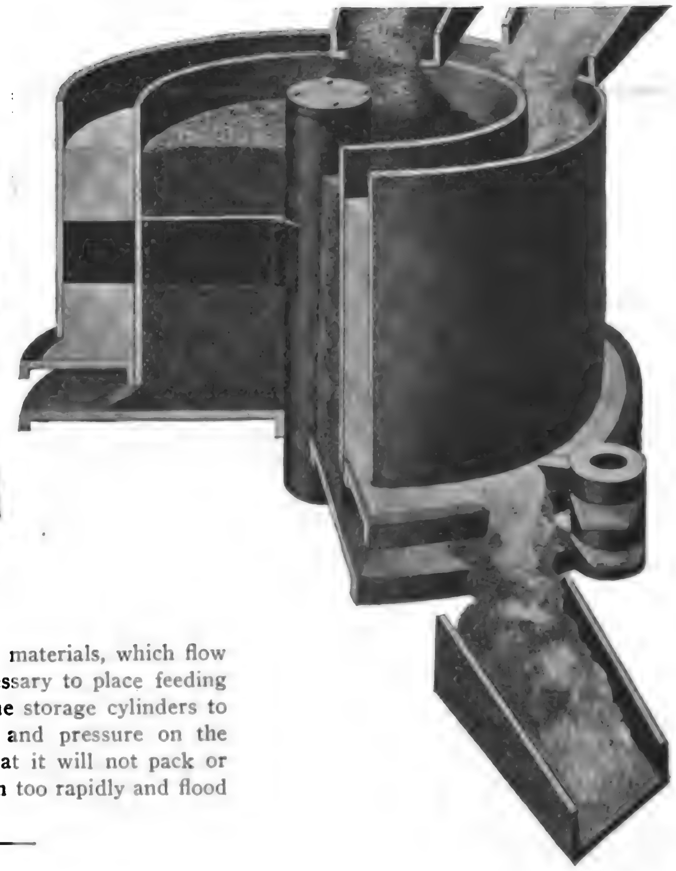

FIG. 11.—SECTIONAL VIEW.

AUTOMATIC MEASURING AND MIXING MACHINE.

The Link-Belt Engineering Company, of Philadelphia, has brought out a continuous measuring machine, which is adapted to feed one substance or to proportion the several ingredients of a mixture. The measuring machine, which was devised by E. N. Trump, consists essentially of a horizontal revolving table, on which the material to be measured rests, and a stationary knife set above the table and pivoted on a vertical shaft outside the circumference. This knife can be adjusted so as to extend the proper distance into the material on the table, at each revolution of which it peels off a certain amount, which falls over the table edge into the chute. This is shown in Fig. 10. The amount of swing of the knife is controlled by a screw attached to an arm, cast as part of the knife, and a micrometer scale with pointer shows the amount of movement. Where it is desired to measure off and mix two or more materials, the machines are made with two or more tables, set one above the other, and mounted on the same spindle so that they revolve together, each table having its own storage cylinder above it, and the cylinders being placed one within the other as shown in Fig. 11. For each table there is a knife, with its own adjusting mechanism, which allows the user to vary, at will, the percentage of each material in a mixture; and, as the materials flow together constantly and regularly in small streams as they drop down the common chute, each amount of one ingredient is accompanied by the proper amounts of the other ingredients, and the particles become intimately mixed. In feeding materials to the storage cylinders of these machines a conveyor is necessary merely to see that enough is kept in the storage cylinders so that the amount which the knives peel off will be constant. With some finely powdered materials, which flow very freely, it is necessary to place feeding seals at the top of the storage cylinders to regulate the density and pressure on the material below, so that it will not pack or flow out at the bottom too rapidly and flood the table.

NEW POLE LINE FUSE BOX.

The H. W. Johns-Manville Company has brought out the pole line fuse box, shown by Fig. 12 herewith, for use on 2,500-volt distribution systems, in connection with Sachs "Noark" fuses. The external casting consists of a cast-iron box having a hinged cover opening sideways. The cover is provided with a rubber gasket, which forms a weather seal between the box proper and the cover, which latter is firmly held in position by the thumb nut hasp. Inside of the iron box is a porcelain box provided with a porcelain cover and fuse holder. When in place the cover is flush with the top surface of the porcelain box, and finds a seat on a rubber gasket placed in a ledge around the inside of the outer walls of the porcelain box. The fuse is held to the cover by means of the well-known "Lobster Claw" device, which consists of a pair of tongs made of a specially treated insulating material, manipulated so as to clamp or release the fuse by means of a nut embedded in the porcelain handle, on the exterior of the cover. This nut works on a stud projecting from the clevis to which the claws are attached. Turning the nut in one direction causes the claws to be brought together to clamp the fuse, so that it is firmly held to the blocks on the porcelain cover. Movement in the opposite direction permits the spring to open the claws and release the fuse. When clamped to the cover, the fuse and cover are manipulated as one device and form practically a plug co-acting with the contacts attached to the base portion of the porcelain box. The fuses are fitted with the so-called type "C" contacts, which consist of flat blades on each side of the fuse tube, forming a knife-blade switch contact. The receiving clips on the base of the porcelain box are

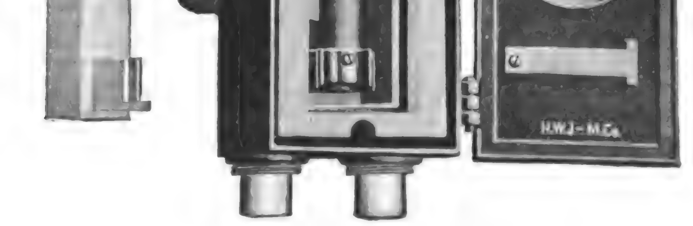

FIG. 12.—POLE LINE FUSE BOX.

made of spring metal and the insertion of the fuse into them is readily accomplished. The arrangement is such that the box is practically closed just before the fuse reaches the contact clips. A novel feature embodied in this box is the method of connecting the box to the line and entirely protecting the current wires from contacting with any of the metal parts of the box. The wires enter the box through porcelain bushings at the bottom of the iron casing. These porcelain bushings are held in position by means of brass rings, which force the head of the porcelain against the bottom of the porcelain box with a rubber gasket intervening. A water-tight joint is, therefore, made. Attached to the clips in which the fuse is received, are brass castings which are so located that the hole in the castings also aligns with the hole in the wall of the box. It therefore becomes a very simple matter to insert the wire. The wire is clamped, after it has been properly placed in the hole of the connecting post by screws easily reached by an ordinary screwdriver. It will be noticed that after the wire once enters the porcelain bushing on the bottom of the box it is entirely surrounded by porcelain, and is perfectly protected from leakage or contact with the non-current-carrying parts of the box.

COMBINATION VOLT-AMMETER.

The Connecticut Telephone & Electric Company, of Meriden, Conn., has placed on the market a new type of volt-ammeter, which is illustrated by Fig. 13. The instrument, which has been designed especially for testing batteries, is made up in two styles—one a combination volt-ammeter and the other reading in amperes only. The scales are graduated from 0 to 30 amperes

FIG. 13.—COMBINATION VOLT-AMMETER.

and from 0 to 6 volts, and are carefully calibrated. The arrangement of the needle supports is said to permit very delicate and accurate reading.

HIGH FREQUENCY ALTERNATOR.

A high-frequency alternator for laboratory experimentation has just been furnished the American De Forest Wireless Telegraph Company by the Peerless Electric Company, of Warren, Ohio. The machine is of two kilowatts capacity, 110 volts at 833 cycles, though in extended tests at the factory it was run for hours at a frequency as high as 5,000 cycles. In designing this generator the engineering department adopted the inductor type, the laminated stationary armature having 200 slots and the rotor one-half that number of teeth. Especial attention was given the mechanical design, to insure stability of all parts. The rotor, which is twenty-five inches in diameter, was made of two rings of steel each forged from a solid piece of metal, the periphery being slotted to form the poles. These rings were shouldered and assembled on a heavy steel disc, through the hub of which passed the shaft of tool steel. Heavy phosphor-bronze bearings are used, lubricated by ring oilers.

CATALOGUES WANTED.

J. Don Alexander, of Keokuk, Iowa, is about to engage in the electrical contracting and supply business, and intends to keep a large stock. He requests from manufacturers and dealers in electrical supplies and appliances latest catalogues, literature, etc., and price lists.

THE STIRLING-CAHALL BOILER COMPANY

A consolidation of interest to the engineering world has just been consummated by the amalgamation of the water-tube boiler business of the Aultman & Taylor Machinery Company, of Mansfield, Ohio, and the Stirling Company, of Barberton, Ohio. The resultant concern is the Stirling-Cahall Boiler Company, which has a capital stock of $4,500,000.

The position of the new company will be unique in that it will be in a position to supply to the trade practically every type of water-tube boiler on the market, since in addition to manufacturing boilers of the Stirling and Cahall horizontal and vertical types, it is said it will shortly take up and place upon the market an improved water-tube boiler of the water-leg type.

Details of the organization have not, it is said, been worked out, but it may be safely assumed that the consolidation will be one of organizations as well as of plants.

An aggressive policy will be maintained in the export department through the foreign connections of the Stirling Company in their offices in Johannesburg, S. A. R.; Havana, Buenos Ayres, Yokohama, the Hawaiian Islands, etc., as well as through their stockholders in the Stirling Boiler Company, Limited, of Edinburgh, which is interested in the water-tube boiler business of Great Britain and the Continent.

The Stirling Company was organized in 1890, and in 1898 established its marine department, securing control of the United States patents on the Niclausse, Yarrow & Mosher boilers, and its growth has been little short of marvelous, its sales in eight years showing an increase of nearly 800%.

The history of the Cahall sales department of the Aultman & Taylor Machinery Company has been equally honorable and creditable and the new company will start with enviable prestige and with every facility for both manufacturing and selling. The general offices will be at 111 Broadway, New York.

TRADE CONDITIONS IN MEXICO AND SOUTH AMERICA.

BY OUR SPECIAL CORRESPONDENT.

The possibilities for the expansion of our export trade in Spanish-speaking countries, referring especially to electrical machinery and equipment, are greater than is generally supposed in the United States. But these possibilities are thoroughly well understood by competing export nations, who have also taken time by the forelock in endeavoring to obtain a firm foothold in the Latin-American republics as a basis for future as well as present developments.

It cannot be denied that Germany and England are outstripping us in the matter of furnishing electrical supplies, among other commodities, to these countries. Under present conditions, the fact that our goods when put to the test place those other nations at a disadvantage evidently cuts no figure in the final result. If we lack that important requisite of successful trading, adequate selling facilities with regard to men and methods, on which after all, much, if not all, depends, we are at a decided discount as an exporting nation. It is obvious, therefore, that we have to contend with other conditions than the quality of our manufactured products, and not until our efforts are on a parity, or modeled on lines similar to those of our competitors, can we hope to compete successfully.

It should be understood by our export manufacturing houses that however competent a home drummer may be, the tact and talent which brought success to his efforts in the United States or English speaking countries, is wasted in Mexico, Argentine or Chili. The salesman who visits the South and Central American republics should thoroughly understand the Spanish language, as well as the business methods of the country, together with a knowledge of native laws with regard to tariff and customs charges, among others, and in their special bearing upon his mission. It is useless to depend upon the aid of the American Consul when one finds himself confronted with vexatious and perplexing matters which are of hourly occurrence due to the lackadaisical business methods common in the countries south of us. The writer has met American salesmen in Spanish-American countries, representative of large houses, finding themselves handicapped by untoward and unexpected conditions, with probably an imperfect knowledge of Spanish, together with inability to comprehend the apparently inexplicable trading system which prevails, so widely different from those to which he was accustomed at home, that in despair they would throw up their hands and long for the return trip. In the meantime it may be observed that the German commercial agent, trained to the situation even before his advent to the country and supported by his Consul or the legation itself, quietly and uninterruptedly proceeds in securing orders from the natives right and left. The position of the German agent is, therefore, that of a formidable, if not unassailable, competitor.

There is one thing, however, which can

be said in favor of our trade with Central and South American nations: The greater our investments, whether in mining, railroading or in agricultural lines, in like proportion will our export trade increase. The investment of American capital has, of course, the natural result, inasmuch as orders for machinery and other equipment are secured to American manufacturers. Our European competitors are, however, alive to this situation also, as evidenced by a report in the Dusseldorf Chamber of Commerce publication, which is to the following effect: "As yet, land can be purchased at low prices," referring to Latin-America, "but if the opportunity is not seized the United States capitalists will purchase out all, which will secure to them orders for machinery of every description to the detriment of German export interests."

Regarding electrical developments in Cuba, it is safe to assume that the bulk, if not all, of the supplies needed will be purchased either direct from the United States or branch American houses in Havana. Apart from the feeling of good-will displayed by the average Cuban toward America and things American, the United States has an advantage over other nations through the preferential rate tariffs accorded it by the Cuban Government. Owing to this fact a number of German manufactured products cannot be exported to Cuba unless at a loss.

If we were to estimate the ratio of progress in electrical developments in Cuba for the next four years, taking as a basis that of the past four years, the result would be surprising indeed. Electric power plants and central stations will cover Cuba from north to south within the next decade. An enormous amount of money is going into Cuba at this time, American investments already amounting to more than one hundred and fifty million dollars.

The Mexican Government has recently issued a pamphlet entitled; "Yesterday and To-day with Mexico." The pamphlet is of more than passing interest to American exporters in electrical lines particularly. Attention is called to the marvelous development of the resources of that country now proceeding, together with a forecast of the equally surprising possibilities. It is obvious to any one who has resided some time in Mexico that outside that country only a few persons have even an approximate knowledge of the gigantic efforts which she has made to place herself, within the space of a few years only, in the high position which she occupies among the Spanish-American republics. The pamphlet further shows the rapidity with which Mexico's foreign trade is increasing; in the one aspect only of its relations with the United States, the import and export, which in 1875 amounted to $11,000,000, has in 1904, reached $90,000,000, this amount being about equally divided between imports and exports.

The Argentine Republic is following closely on the heels of Mexico, but latest advices from that country are to the effect that the duties on imported manufactured goods will be increased in the near future.

Notes.

Late advices from Mexico are as follows: Pedro Alvarado, the multi-millionaire mine owner, has awarded to Weisel & Kock, of Parral, Chihuahua, the contract for installing a new electric power plant at his Palmullio mines. Boilers are to be of the high-pressure variety; engine, of the standard Corliss make, compound-tandem, with direct-connected 700-kw. alternating-current generators, 2200 volts and exciter. Weisel & Kock are in the market for electrical supplies, such as their contract requirements call for, and it is worthy of note that the Mr. Alvarado, who has placed the contract, is the same who volunteered to the Mexican Government to pay off the entire national debt.

The State of Vera Cruz has granted to Alfredo Kennion a concession for the construction of a suburban railroad system connecting the several towns in the neighborhood of Orizaba with the latter, the question of generating electrical power from the neighboring waterfall, which is of immense volume, being under consideration.

A concession will be granted by the State Government of Jalisco to Carlos Romero, of Hostotipaquilla, Jalisco, to construct an electric railroad to Etazatlan.

Colonel W. C. Green, the copper king of Cananea, Sonora, has organized a $15,000,000 stock company, part of whose plans is to build and operate a paper mill, the motive power to be electric.

The Peregrina Mining Company, operating in Guanajuato, recently purchased forty stamp mills from the Fulton Iron Works. They intend to erect a cyanide plant with a capacity of 250 tons, to be operated by electric power.

Work is being pushed on the electric power plant of the Black Mountain Mine Company, near Magdalena, Sonora. The plant will operate a stamp mill 35 miles off, and it is expected to be in operation by January of next year.

Colonel Daniel W. Burns, political boss of California and sole owner of the Candalaria mines in the San Damas district of the State of Durango, is having plans prepared for a hydro-electric plant. A mighty waterfall will be harnessed and the electric power will be sufficient to operate a number of mines, as well as a reduction plant in that neighborhood.

George G. Bergman, of the City of Mexico, has applied for concession to develop water power and build an electric plant on the River Blanco, Corooba Canton, Vera Cruz.

Vicente Martinez, of the City of Mexico, will build an electric plant for the transmission of electric power at Xicotlacotia between the States of Morelos and Guerrero.

La Electra Company, of Guadalajara, Jalisco, has authorized an issue of $2,000,000 of mortgage bonds for financing the construction of an electric street railway system in that city.

I. W. Conger, of Mexico City, brother of the United States ambassador, will construct an electric power plant in Chihuahua for the purpose of operating a street railway in that city.

The Mexican-American Power Company, recently organized and composed of Philadelphia capitalists, is about to undertake the largest electrical project over previously contemplated in Mexico. The amount of capital to be invested is $10,000,000, and of this sum $1,500,000 has already been subscribed. The project consists in erecting a series of electric power plants, three of them, it is understood, to be of sufficient capacity to generate 90,000 horse-power. Joel H. De Victor and A. S. Harvey, both of Philadelphia, are president and vice-president, respectively, of the company.

It should be noted that many articles of American manufacture are affected by the increase of import duties made by the Mexican Government, and which became effective the first of the present month. The duties are based upon the weight per kilo of 2½ pounds. The gross kilo includes the entire packing or casing, and the legal kilo is that prescribed in the traffic act. The rating on electric lamps per gross kilo is 11 cents, and on arcs per gross, 6 cents.

OBITUARY.

MR. EDWIN R. WHITNEY, the well-known engineer, died at the Margaret Pillsbury Hospital, Concord, N. H., on September 1. Mr. Whitney was head of the Whitney Electrical Instrument Company. He was the inventor and patentee of a voltmeter and a number of other instruments for the measurement of electrical currents. He was also interested in the development of the Shawinigan Falls Water Power Company, of Canada.

PERSONAL.

MR. R. F. HAYWARD, chief electrical engineer of the Utah Light & Power Company, has been appointed manager of the Mexican Light & Power Company, Mexico City, Mexico.

MR. E. A. REGESTINE has resigned as instructor in electrical engineering at Lehigh University, and accepted a position in the general sales department of the Standard Underground Cable Company, at Pittsburg, Pa.

MESSRS. DAVID PEPPER, JR., AND ALBERT REGISTER announce that the firm of Pepper & Register, engineers and general contractors, has been dissolved and succeeded by A. L. Register & Co.

MR. J. B. COWEN, formerly connected with the General Incandescent Arc Light Company, has been appointed manager of the sales department of the General Storage Battery Company, of New York City.

MR. B. H. WARREN, who retired from the presidency of the Allis-Chalmers Company on September 1, will, it is said, become the head of a new engineering and contracting company which is to be established in New York and which has several powerful interests associated with it.

MR. H. F. STRATTON, who has been connected with the principal office of the Electric Controller & Supply Company at Cleveland, Ohio, has accepted the position of New York representative of that company, with offices at 136 Liberty Street.

MR. CHARLES GARLAND has resigned as secretary of The Westinghouse Machine Company and accepted the vice-presidency and treasurership of the Pittsburg Fire-Proofing Company. Mr. Garland has been connected with The Westinghouse Machine Company for over twenty-one years and carries with him the best wishes of his former colleagues in his new field of activity.

MR. JAMES C. HAIN has resigned as engineer of masonry for the Chicago, Milwaukee & St. Paul Railroad and is now associated with J. G. White & Co., as superintendent of masonry construction, with headquarters at 43 Exchange Place, New York.

MR. RANDOLPH STRICKLAND, who for the past year has been assistant engineer in the Maintenance of Way department of the New York Central Railroad, has resigned from that position and joined the staff of J. G. White & Co., as assistant to the secretary. Mr. Strickland is a graduate of the Massachusetts Institute of Technology.

MR. W. G. CARLTON, formerly connected with the Chicago Edison Company, has been appointed superintendent of power of the electrical zone of the New York Central & Hudson River R. R. Company. Mr. Carlton will have charge of the two main electric power stations which the company is building near New York, the eight sub-stations and the transmission system. Mr. Carlton is a graduate of Cornell University.

MR. PUTNAM A. BATES has taken over the engineering busines of Bates & Neilson, from which Mr. John Neilson, who has been in poor health for the past six months, has retired. Mr. Bates gives special attention to the preparation of plans and specifications, supervision of electrical installations, special investigations and reports, and the application of electric power to machinery. He will continue the business at the old address, 42 Broadway.

MR. EUGENE HOLCOMB has been appointed manager of the newly created Foreign Department of the Allis-Chalmers Co., which includes supervision of all the foreign agencies and foreign selling representatives of the company. Mr. Holcomb is thoroughly familiar with engineering possibilities and projects in South America, having spent a number of years there. His headquarters will be at the general offices of the company at Milwaukee, Wis.

MR. M. A. PEARSON, of the Farrell Foundry & Machine Company; S. J. Gilpin and Thomas Waters, both of the Birmingham Iron Foundry; C. E. Miller, formerly of the Diamond Rubber Company; and William Spire, formerly of the Chase Machine Company, have joined the staff of the Aiton Machine Company and will devote their time exclusively to the rubber mill department of the company. Their headquarters will be at 126 Liberty Street, New York.

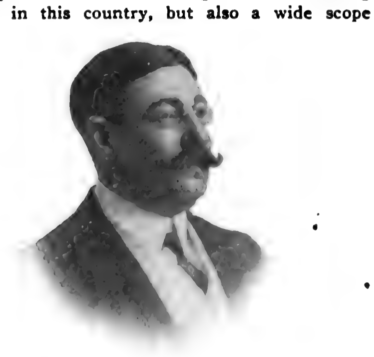
MR. WALTER H. WHITESIDE has been recently elected president of the Allis-Chalmers Co., succeeding Mr. B. H. Warren, whose retirement is noted elsewhere in this column. Mr. Whiteside joined the Allis-Chalmers forces in July, 1904, when he accepted the position of general manager of sales. At that time the company had just taken over the Bullock Electric Manufacturing

W. H. WHITESIDE.

Company and needed the injection of a vigorous and energetic personality into its sales forces. His promotion to the presidency indicates with what success Mr. Whiteside has met in his efforts. In his more responsible position, Mr. Whiteside has behind him the confidence of his organization, as well as a long and varied business experience, during which he has filled many executive positions. His achievements have won him recognition as a man of marked administrative ability. Mr. Whiteside is a member of the American Institute of Electrical Engineers, of the Engineers' and Lawyers' Clubs, of New York, of the Mid-Day Club, Chicago, and of the Milwaukee Club.

MR. H. F. J. PORTER, formerly manager of the American branch of the Westinghouse Companies' Publishing Department and afterwards second vice-president and general manager of the Nernst Lamp Company, has opened an office at 1 Madison Avenue, New York, as a consulting industrial engineer. Mr. Porter will devote his time to consulting industrial engineering practice, installing modern methods of organization and management leading towards industrial betterment, and welfare work.

MR. W. S. DORAN, formerly associated with the British Westinghouse Manufacturing Company, Ltd., has been appointed manager of the power department of the Allis-Chalmers Co. Mr. Doran will have full charge of the company's commercial affairs pertaining to reciprocating steam engines, steam and hydraulic turbines, condensers, gas engines, blowing engines for iron and steel blast furnace service, and rolling mill engines. Mr. Doran is well qualified to carry on this important work, having not only acquired knowledge in some of the largest manufacturing concerns in this country, but also a wide scope



W. S. DORAN.

of technical training through many years spent abroad. Mr. Doran has been connected with such concerns as the Southwalk Foundry & Machine Company, United Gas Improvement Company, Henry R. Worthington, and with the Westinghouse interests. He was tendered a banquet on the eve of his departure from England, which was attended by many well-known railway officials, manufacturers, electrical engineers, and representatives of practically all the large electrical manufacturing concerns in England.

TRADE PUBLICATIONS.

TESTING METER. General Electric Company.—Bulletin No. 4420, illustrating and describing the type I. B. Thomson high-torque induction test meter.

RAILWAY MOTOR. Westinghouse Electric & Manufacturing Company.—Circular No. 1120, in which is described the company's 113 railway motor for direct-current service.

TELEPHONE SWITCHBOARDS. The Dean Electric Company, Elyria, Ohio.—Folder No. 8, describing the No. 2 type of common-battery switchboards manufactured by this company.

TESTING INSTRUMENT. Queen & Co., Inc., Philadelphia, Pa.—Circular No. 605, devoted to new testing instruments for measuring resistance.

OIL ENGINES. De La Vergne Machine Company, New York.—A handsomely executed catalogue of standard size, describing the Hornsby-Akroyd oil engine, the American license for which is owned by the De La Vergne Machine Company.

STORAGE BATTERIES. National Battery Company, Buffalo, N. Y.—Bulletin No. 2, describing the installation of "unit accumulators" for the Syracuse & Suburban Railway Company, Syracuse, N. Y.

CONTINUOUS OILING SYSTEMS. Pittsburgh Gage Supply Company.—A well-executed catalogue describing the White Star continuous oiling system made by this company, together with methods of installation.

MINIATURE LAMPS. The Federal Miniature Lamp Company, New York.—A well-executed catalogue of standard size, illustrating every type and style of incandescent lamp in general use, with or without bases, of less than one inch in diameter.

VALVE SPECIALTIES. Golden-Anderson Valve Specialty Company, Pittsburg, Pa.—Pamphlet No. 4, entitled "Worth Has Won," and describing the various valves made by this company, many of which have been illustrated and described in the columns of this paper.

CALENDAR. The Bryant Electric Company and the Perkins Electric Switch Manufacturing Company, Bridgeport, Conn.—A card the upper half of which shows a picture of the factories of the companies mentioned, and the lower half containing a calendar pad from September, 1905, to December, 1906, inclusive.

BELT-DRIVEN GENERATORS. National Electric Company, Milwaukee, Wis.—Bulletin No. 355, devoted to a description of the type MB, direct-current generators manufactured by this company. These are built in capacities of 50 to 800 kilowatts, with speeds and voltages to suit requirements.

MAGNETO SIGNALLING APPARATUS. The Holtzer-Cabot Electric Company, Boston, Mass.—Bulletin No. 200, containing a description of bridging and series magneto bells, central energy sets, hand generators, extension bells, toll line indicators, circuit closers, ringers, magneto generators, gravity hooks, etc.

VOLTMETER AND FREQUENCY INDICATOR. Wagner Electric Manufacturing Company, St. Louis, Mo.—Bulletin No. 73, describing a combined voltmeter and frequency indicator brought out by the Wagner Company. The instrument is built for any voltage and frequency and is provided with two scales, one reading "volts" and the other "cycles."

DIFFUSER CEILINGS. American Metal Stamping Company, Inc., Philadelphia, Pa.—Bulletin A-21, devoted to the light balancing selective diffuser ceilings. These ceiling are made of steel with impressed designs on the surface to give an excellent diffusion of light. The bulletin also contains a treatise on the subject of color and distribution of artificial lights.

WIRELESS CLUSTERS. Benjamin Electric Manufacturing Company, Chicago, Ill.—A 64-page catalogue, in which is listed a number of new specialties and improved forms of wireless clusters. The catalogue is accompanied by an eight-page folder illustrating the ceiling, fixture, suspension and out-door forms of the "arc-burst" cluster.

STRANDING MACHINE. Aiton Machine Company, New York.—Bulletin No. 62, describing the company's 18-drum stranding machine. The drums are carried in steel cradles which are connected by cranks to an eccentric ring for keeping torsion out of the wires. The machine is driven from the front and can be used as a separate unit or in tandem with others. Cut gears are used throughout. The die holder is adjustable in each direction and is adapted for split dies.

BUSINESS NEWS.

COMMERCIAL ELECTRIC SUPPLY COMPANY has recently moved to new headquarters at the northwest corner of Fifteenth and Pine Streets, St. Louis, Mo.

THE AMERICAN ARC LAMP COMPANY, successor to the Lea Electric Manufacturing Company, of Elwood, Ind., is now located at Kalamazoo, Mich., in new and larger quarters.

PEPPER & BOWIE have opened an office in the Land Title & Trust Building, Philadelphia, as engineers and general contractors. The firm will specialize in electric roads, water-power plants, general contracts and reports and estimates.

THE RELIANCE ENGINEERING COMPANY has opened offices at 701 Traction Building, Cincinnati, Ohio, for consulting and contracting engineering work. Mr. Laurent Lowenberg is the electrical engineer.

ELECTRIC APPLIANCE COMPANY, of Chicago, states that owing to the convenience of its new and well-filled store-rooms it is able to keep pace with demands, for electric lamps, all orders being promptly filled from Chicago stock on the day of their receipt.

BOSTON INCANDESCENT LAMP COMPANY, Danvers, Mass., reports that it supplied all the incandescent lamps used at Steeplechase Island, a popular resort at Bridgeport, Conn. Seventy-five thousand lights were connected for illuminating purposes.

CHARLES R. UNDERHILL, New York City, has recently issued a sheet, with 35 illustrations, showing the various types of alternating and direct-current electromagnets. A pamphlet, entitled "Facts About Electromagnets," accompanies this sheet, both of which may be had on request at his office, at 55 Liberty Street, New York City.

GEORGE W. LORD CO., Philadelphia, states that with the cessation of hostilities in the far East they have again resumed the shipment of Lord boiler compounds to Japan and Russia. In addition to filling standing orders, a cable order was recently received from Vladivostock for a carload of compound to be shipped via Seattle, Wash.

STROMBERG-CARLSON TELEPHONE MANUFACTURING COMPANY, Rochester, N. Y., reports having closed contracts for switchboards for the following places: Mt. Pleasant, Ill.; Hunter, N. D.; Union, Miss.; Harris, Pa.; Des Moines, Ia.; Roann, Ind.; Tower Hill, Ill.; Milacca, Princeton; Foley, North Branch, Rush City, Mora, Forest Lake, Grandy, Lindstrom, Braham, Minn.; Olathe, Kan.; Rochester, N. Y.; Truro, Ia., and Kalama, Wash.

MACHADO & ROLLER, of New York City, have recently opened a branch office in the Monadnock Block, Chicago, where it is intended to carry a varied assortment of standard Whitney instruments, so that prompt deliveries may be made to the local trade. Secondary standards for purposes of comparison are kept constantly on hand, and facilities for making simple repairs in Chicago are also provided. The office is in charge of Mr. H. I. Shire, formerly of New York.

THE EUREKA ELECTRIC LAMP COMPANY, of Cleveland, Ohio, and the St. Marys Incandescent Lamp Company, St. Marys, Pa., have been consolidated under the name of the St. Marys Incandescent Lamp Company, with a capital stock of $100,000. The company proposes to engage in the independent manufacture of incandescent electric lamps, and for that purpose is erecting a new factory at St. Marys, Pa., which is to be equipped with the latest and most improved machinery.

COPLEY-SENIOR CARBON COMPANY, New York, have perfected a brush which is claimed to be thoroughly self-lubricating, noiseless, non-sparking, non-cutting, and uniform throughout; retaining these qualities until entirely worn out. The carrying capacity of the brush is said to be very good. Mr. George W. Copley is president and general manager; Mr. George W. Enos, vice-president, and Mr. John L. Senior, secretary and treasurer of the company, whose office is at 465 Greenwich Street, New York City.

J. G. WHITE & CO., New York, are building for the Waltham Gas Light Company, of Waltham, Mass., a power house of re-enforced concrete. Steam will be supplied by four 350-h.p. Sterling boilers, an 8½x180-ft. re-enforced concrete stack furnishing natural draft. Suspended coal bunkers will occupy the upper half of the boiler-room; these will be filled by coal conveyors, and chutes operated by valves from the boiler-room floor will convey the coal to the boilers. Two 500-kw. Westinghouse-Parsons turbo-generators form the main generating equipment.

B. F. STURTEVANT CO., Boston, Mass., has supplied through its engineers, Sanderson & Porter, New York City, to the New Orleans (La.) Railway Company six large economizers which are unique in that they are built to withstand the highest pressure to which an economizer is known to have been subjected. The pipes are tested to 600 pounds pressure before they leave the works, and each section is tested to 500 pounds after the pipes are inserted. There is but a single gasket joint running through the machine, this joint being made of two heavy flanges on a special gasket which has 2¾ in. plain surface through the entire circle. The company has also supplied the Wilkesbarre (Pa.) Gas & Electric Company with a forced-draft apparatus feeding six 225-h.p. boilers.

THE WESTINGHOUSE MACHINE COMPANY reports that during the past month orders have been received for no less than fifty-one Roney mechanical stokers ranging in size from 54 in. x 20 grate to 132 in. x 26 grate, the largest of the orders being that of the Pennsylvania Railroad for six 132 in. x 26 grate stokers and five 100 in. x 20 grate stokers. A large order from the Ohio Hospital for Epileptics, at Gallipolis, Ohio, has also been received, and others from the American Bridge Company, Ambridge, Pa.; National Tube Company, Pittsburg, Pa.; Detroit United Railway Company, Detroit, Mich.; York Engineering Company, York, Pa.; Proctor & Gamble Co., Cincinnati, Ohio; The Union Rolling Company, Cleveland, Ohio; Gulfport and Mississippi Coast Traction Company, Gulfport, Miss.; United Presbyterian Board of Publication, Pittsburg, Pa.; Indiana Boys' School, Plainfield, Ind.; B. & O. Office Building at New York City, and the Railway Exchange Building at Chicago, Ill.

THE ABNER DOBLE COMPANY, of San Francisco, has recently received several interesting orders for Doble tangential water wheels. Prominent among them is an order from the California Gas & Electric Corporation for a 9000-h.p. wheel for its De Sabla power plant. The wheel will operate under a head of 1530 feet at 400 r.p.m. and will be driven by a single jet of water, thus making it the most powerful water wheel ever constructed for operation under a single jet of water. Another order from the California Gas & Electric Corporation calls for six 570-h.p. wheels for its Nevada City plant. Those will operate under a 190-foot head at 410 r.p.m. A 400-h.p. Doble wheel for operation under a 400-foot head, equipped with jet deflector operated by a Woodward compensating governor, has been shipped to the Chancellor Gold Mining Company, Wenatchee, Wash. The La Grande Water Storage Company, La Grande, Ore., has purchased an 800-h.p., 1150-ft. head, 600 r.p.m. Doble wheel, equipped with Doble needle regulating nozzle for operation by a Lombard governor. Among other recent orders secured by the company are two double 1750-h.p. wheels for the San Joaquin Power Company, Fresno, Cal., for operation under 385-ft. head; one Doble needle regulating nozzle for a large water-wheel for the Komata Reefs Gold Mining Company, New Zealand, and a double 700-h.p. water wheel unit for Mitsui & Co., Japan, for operation under 210-ft. head, this order including the wheel complete with Lombard governor and gate valve. The University of Michigan has purchased the Doble tangential water wheel which the Abner Doble Co. exhibited at the St. Louis World's Fair and for which the company was awarded the grand prize. This wheel is to be installed in the hydraulic laboratory of the new Engineering Building at Ann Arbor, Mich., where it will be mounted in connection with a Duplex pump for experimental purposes, its output being 100 horse-power when operating under a head of 580 ft. The 12-in. laboratory water motors which the Abner Doble Co. builds for technical schools and universities have attracted considerable attention among the engineering faculties of many of the leading educational institutions, and the interest shown in these small water wheels has resulted in an increasing demand for them, orders having recently been received from the University of Wisconsin, the Michigan School of Mines and the University of Toronto.

CENTRAL STATION NEWS

Readers are cordially invited to contribute to this department items of news relating to plants in their vicinity.

ALABAMA.

ALBERTVILLE.—A number of the business men of Albertville have organized a company to be known as the North Alabama Railway, Light & Power Company, with a capital of $100,000. The purpose of the company is to connect all Sand mountain towns with an electric railway, provide water works for the larger towns and to light the towns with electricity. J. G. Elrod, president; N. A. Elrod, vice-president and business manager, and W. M. Coleman, secretary.

CARBON HILL.—Bids have been called for a water and light plant, work to include erecting a brick or concrete block power house, furnishing a 100-h.p., high-speed automatic engine; two 100-h.p. boilers and fittings, furnishing one compound, one duplex and one feed pump; furnishing and erecting an 80,000-gal. steel tank and tower; constructing an 80,000-gal. surface reservoir, and furnishing a 60-k.w., 60-cycle, single-phase, 2300-volt alternator, together with exciter, switchboard and station instruments; pole line, transformers and twenty standard 6.6-ampere, series inclosed arc lamps of latest design.

ARIZONA.

ROOSEVELT.—Bids will be received until November 1 by O. H. Ensign, Electrical Engr. U. S. Reclamation Service, Los Angeles, for furnishing complete f. o. b. bidders' works, one or more alternating-current, 900-k.w., 25-cycle generators, one or more 100-k.w., direct-current generators for exciter, and a switchboard containing one panel for generator and one panel for exciter, for use in Roosevelt power house, Salt River Project, Ariz.

CALIFORNIA.

LOS ANGELES.—The Yuma Electric & Water Company is reported incorporated, with a capital of $100,000, by A. A. Talmage and others.

BEN LAMOND.—The Ben Lamond Light Company will extend its service to Felton, three miles distant, and the line is under course of construction.

AVALON.—The Santa Catalina Island Company is arranging to increase the capacity of its plant, by installing larger direct-connected engines.

ANAHEIM.—C. A. Copeland, of Los Angeles, is stated to have estimated the cost of the proposed improvements to the electric light plant at $22,000 and to the water works at $18,250.

GILROY.—Bids are being considered by the Mayor and Common Council for $11,000 bonds for electric light and power works and an electric lighting system. C. N. Hoover is city clerk.

OROVILLE.—The Oroville Water, Light & Power Company has issued specifications calling for the equipment of its new water power electric transmission plant. Two 750-kw., three-phase generators 2000 to 2300 volts, with alternative of two 1000-kw. generators are included. There will also be required raising and lowering transformers, switchboard and sub-station equipment. Cory, Meredith & Allen are the engineers.

RIALTO.—A. L. Selig, manager of the Edison Electric Company, it is reported, has made a proposition to the citizens of Rialto to extend a wire for 10,000 volts from San Bernardino, the Rialto citizens to establish their own local operating company, furnish wires, meters, transformers, etc.

SAN LUIS OBISPO.—B. F. Thomas, manager of the San Luis Obispo Gas & Electric Company, states that the C. C. Moore Company, of San Francisco, has secured the contract for constructing a new plant of 270-kw. capacity. A. M. Hunt, of 614 Mission St., San Francisco, is the engineer.

SAN BERNARDINO.—The Little Creek Power Company, it is reported, has engaged F. A. Worthely, superintendent of the Riverside electric light plant, to prepare plans and specifications for its steam plant and distributing system in this city. It is reported that bids are soon to be asked.

YREKA.—The Siskiyou Electric Power Company has awarded a contract to the Pelton Water Wheel Company for a 2000-h.p. water wheel for direct connection to a 1000-kw. engine-type generator running at 360 r.p.m., the effective head being 700 feet. This is a duplicate of the wheel installed a couple of years ago.

LOS ANGELES.—The Council has adopted a report of the Lighting Committee, it is stated, in which it is recommended that the City Clerk ask bids for municipal lighting under the following terms: one year contract, not to exceed 2000 lights, three-year contract not to exceed 2500 lights and five-year contract not to exceed 3000 lights.

FERNDALE.—An ordinance has been adopted by the Board of Supervisors, granting to the Ferndale Electric Light Company (W. W. Barnes, secretary, Ferndale), a franchise to construct poles, wires and other conductors for electric purposes along the road in First Supervisorial District, of Humboldt County. W. H. Haw, County Clerk.

POMONA.—It is reported that the farmers and orange growers in the vicinity of Pomona are organizing a company to build an electric power plant with which to furnish power for all pumping plants in the vicinity and operate a belt trolley line, connecting all the near-by towns and ranches, including Chino, Ontario, Claremont, North Pomona, Lordsburg, San Dimas and Covina.

SAN FRANCISCO.—The Eel River Power & Irrigation Company is building the pole line on its 22-mile transmission from Potter Valley to Ukiah. It is probable that a transmission line will be built to San Francisco, a distance of 130 miles, as the market for power near the plant is limited. The machinery ordered includes two 2000-kw., three-phase generators and two Victor turbine water wheels.

STANISLAUS.—The Stanislaus Water & Power Company, for which Sanderson & Porter acted as engineers, is doing preliminary work under the direction of Beach Thompson, the promoter. It is proposed to build dams for catching up all the water of the Stanislaus River and conveying it by means of ditches, flumes, etc., to Sulbets Flats to a point where a drop of 1500 feet can be had, and where the power plant is to be installed.

SAN FRANCISCO.—The California Gas & Electric Company has completed the installation of two additional 5000-kw., three-phase generating units at its Electra power station. This addition to the three generators already in operation gives the Standard Electric transmission line a large capacity. The company will also install two additional 1000-kw. polyphase generators on the South Yuba transmission system, which was acquired from the Van Nordens. There is an unlimited amount of water available for further development on the South Yuba.

SAN FRANCISCO.—It is reported that the Tuolumne Electric Company, which is constructing a water-power electric plant near Tuolumne, Cal., has arranged to sell power to operate the projected Kemp, Van Ee electric road from Santa Cruz to Hollister and to the new cement works to be erected in the San Juan Valley. H. Hersey is president and C. W. Quilty manager of the electric power company. The machinery contracted for includes two 600-kw. Bullock, three-phase generators and a 1200-h.p. Platt Iron Works wheel operating under 425-foot head.

FRESNO.—A deed has been filed with the recorder transferring the property of the San Joaquin Power Company to the San Joaquin Light & Power Company, to enable work to be done with a larger capital than possible under the old company, which was incorporated for $800,000. The new corporation has a capital of $3,000,000. It is understood that no outside capital has been taken in, the expansion being from within. The action was necessary to cover the plans in contemplation for the development of more than 50,000 horsepower for use in the valley.

COLORADO.

LAKE CITY.—The Hinsdale Electric Light & Power Company is making several changes in its plant and equipment, the most important of which is the establishment of a day circuit. New machinery is being installed to provide for the additional service.

CONNECTICUT.

NORWICH.—The Uncas Power Company, has been incorporated with a capital of $1,000,000.

NORWALK.—It is stated that the Mayor is to appoint a committee of three to investigate the cost of installing a municipal lighting plant.

STERLING.—The Sterling Power Company has been incorporated with a capital of $500,000, and will distribute electric light and power to the towns of Sterling, Plainfield, Brooklyn and Killingly.

NEW HARTFORD.—The Northern Connecticut Power Company, of New Hartford, has been incorporated to operate in Litchfield, Hartford and Tolland Counties under certain restrictions, and is to develop water power on the Farmington River.

PACKERSVILLE.—Negotiations are now in progress for the purchase of the Packer power privilege here in behalf, it is understood, of the New York, New Haven & Hartford Railroad, which wishes to erect an electric power station for the eastern Connecticut branch of the Consolidated Railway Company and to furnish lighting for Wauregan, Moosup, Plainfield and other nearby towns.

RIDGEFIELD.—There is every prospect that Ridgefield will have a new electric plant in the immediate future. A meeting of the stockholders of the Ridgefield Electric Company has been held, at which the following directors of the company were elected: Henry E. Anderson, John A. Mitchell, George Pratt Ingersoll, George G. Haven, Jr., Dr. R. W. Lowe, Albert H. Wiggins; secretary, Harvey P. Bissell. Mr. Kirk has been made general superintendent and assistant secretary of the Electric Company.

KENSINGTON. — The directors of the Kensington Water Power Company, of Kensington, have voted to dissolve the corporation and to wind up its affairs. A final dividend of $1,729 has been declared and distributed among the stockholders. The company was organized in 1890 to secure control of the water privileges which were then held by the Anglo-American Electric Company. Recently the Kensington company sold the privileges and rights to the American Paper Goods Company, which had previously operated them under lease. The water company has been financially successful.

NEW MILFORD.—The Connecticut Railway & Lighting Company has acquired ownership of the New Milford Water Power Company. The property was organized in 1893, and had outstanding capital of $1,000,000, and bonds amounting to $1,000,000. The concern built a large plant near New Milford and drained the Housatonic River near Bull's Bridge and other places to supply power. It had a 30-year contract to supply power to the Connecticut Railway & Lighting Company at $130,000 a year. The power is used to operate trolleys near Waterbury and other places. The bonds of the New Milford Water Power Company are now guaranteed by the purchasers. The officers in the New Milford Water Power Company are: Winthrop Bushnell, president; Louis E. Stoddard, vice-president, and Samuel G. Morehouse, secretary and treasurer, all of New Haven. The company's Waterbury station was described in the June number of this paper.

FLORIDA.

QUINCY.—The citizens are reported to have voted to issue $5000 bonds for improving the water works and electric light plant.

ST. PETERSBURG.—The St. Petersburg Investment Company, which owns the electric light plant and street railway, contemplates moving the plant and reconstructing it with the addition of a 350-h.p. boiler and two 250-h.p. engines.

JACKSONVILLE.—Bids will be received until October 4 by the trustees of the water works and improvement bonds for furnishing and setting in place on foundation furnished by the board at the electric light station two 500-k.w. steam turbo-generators, a steam-driven exciter set and switch panels; turbines to be run condensing, steam pressure at boilers 150 lbs., no superheat, 27 in. of vacuum; generators to be of the revolving-field type, three-phase, 60 cycles 2,300 volts. Blue prints and specifications are to be furnished with bids. Mr. R. N. Ellis is the superintendent.

GEORGIA.

SAVANNAH.—The City Council has passed the ordinance granting a franchise to the Savannah Lighting Company.

JACKSON.—The citizens are reported to have voted September 5 to issue $40,000 bonds for water works and an electric light plant.

ATLANTA. — The Southern States Electric Company has been incorporated with a capital of $20,000 by Joe W. Little and Charles M. Coyen.

WASHINGTON.—Capt. J. H. Fitzpatrick, of Washington, is reported to have purchased the Anthony Shoals property in this county, and will develop this power on the line between Wilkes and Elbert counties and transmit same to Washington, Elberton and Anderson, S. C., and build a railroad from Washington to Elberton.

HAWAII.

HONOLULU.—The plant recently furnished the Hawaiian Electric Company on the Island of Kauai, is about ready to be installed. This consists of a double Pelton unit of the overhung type, operating under a head of 550 feet and direct-connected to a 1,200-kw. generator running at 375 r.p.m., the water wheel having a maximum capacity of 2,500 horse power. Power is transmitted electrically a considerable distance, and is used in connection with pumping for irrigation, which is attracting much attention of late.

IDAHO.

TETON.—The Fremont Light & Power Company has been incorporated, with a capital stock of $25,000.

WEISER. — The Swan Falls Light & Power Company is reported to have petitioned for a franchise to light the city.

SANDPOINT. — The Sandpoint Electric Company is reported to have sold its plant to the Pend d'Oreille Electric Company, having a capital of $50,000.

BOISE. — The Boise-Payette Electric Power Company recently increased its equipment by the addition of another 500-kw. generator and turbine.

MOSCOW. — The Moscow Electric Light & Power Company, it is stated, contemplates extending its lines in the near future to Pullman and Palouse, Wash.

GRANGEVILLE. — The Grangeville Electric Light & Power Company is doubling its hydraulic electrical outfit in order to meet the increased demands for lighting and power service.

MOUNTAIN HOME.—The new $35,000 plant which Mr. Seymour J. Bell, of Sumpter, Ore., has been erecting here, is nearing completion, and it is expected that the town will be furnished with lights therefrom very shortly.

BLACKFOOT.—E. W. Wade, of Ogden, and Christian Just, of Blackfoot, are reported to be interested in the construction of a power plant on Blackfoot River, to supply Idaho Falls, Blackfoot and other cities with electric light and power; probable cost of plant, $100,000.

ILLINOIS.

PEKIN.—The Tremont electric light and power plant will be rebuilt.

MORRISON.—The Morrison Electric Lighting Company has increased its capital stock from $20,000 to $60,000.

BELLEVILLE.—The City Council has appointed engineers to prepare estimates of the proposed municipal electric lighting plant.

FREEBURG. — Charles Kessler, village clerk, states that the proposed municipal electric light plant will cost about $9,000. No engineer has been selected yet.

CUBA.—A new 150-h.p. engine, simple automatic, and a 100-kw., single-phase, 125-cycle alternator is to be installed in the municipal plant. L. Monch. superintendent.

SPRINGFIELD.—The City Council is reported to have authorized the Mayor to take over the properties and plant of the Springfield Electric Light & Power Company.

GLASFORD.—Reports state that steps are under way for the establishment of an electric light plant, but none of the particulars concerning the project are known as yet.

CHICAGO.—The Gillett Light Company has recently changed its title to that of the Standard Gillett Light Company and increased its capital stock from $5,000 to $30,000.

BLOOMINGTON.—A syndicate of Detroit capitalists, headed by Emanuel T. Beyer, has purchased the Union Gas Light & Electric Company for $400,000, the amount of the capital stock.

EUREKA.—W. J. Whetzel, it is stated, has secured the contract to light the city until June 1, 1906. The bid submitted was $2.50 per light per month until midnight and $3 per light per month until 1 A. M.

CHICAGO.—Bids will be received until November 1 by the Board of Trustees, Sanitary District of Chicago (S. D. Griffin, clerk), for constructing a canal lock, movable dams and a fender wall, in connection with the water power development now being made near Lockport.

VANDALIA.—The Vandalia Light & Fuel Company recently sold its electric light plant to the city of Vandalia for $18,000. A number of taxpayers have since filed suit to enjoin the consummation of the sale on the grounds that the city is already indebted beyond the constitutional limit and has no right to engage in the business of selling light.

INDIANA.

GENEVA.—The Town Council has granted W. R. Thurston a franchise for an electric light plant.

DANA.—F. R. Calvert has been awarded the contract for constructing the proposed electric light plant in this city.

JASONVILLE.—It is reported that the Jasonville Electric Company (James H. Parsons, president) will soon ask bids for constructing an electric light plant here.

CLINTON.—The Clinton Electric Light Company has purchased and will install two Westinghouse dynamos and one 150-h.p. Hamilton-Corliss engine. A new dynamo room is being built.

VAN BUREN.—The Huntington Light & Fuel Company (F. D. Townsend, superintendent) has petitioned the City Council for a franchise for the erection and operation of an electric light plant in this city.

VALPARAISO.—The Valparaiso Lighting Company has been incorporated, with a capital stock of $150,000. The directors are Clarence H. Geist, Charles B. Kelsey, H. W. Noble, Edward Clifford and D. S. Davis. This is a new company which recently bought the plant and property of the Valparaiso Light & Fuel Company for $60,000.

PERU.—A statement for the year ended June 30, 1905, has just been issued by the committee having in charge the municipal lighting plant at this place. The city maintains 130 lamps at an average cost of $26 per lamp per year. An expenditure of $30,000, the committee reports, is needed to put the plant in good condition.

INDIAN TERRITORY.

MUSCOGEE.—The plant of the Muscogee Electric Light & Power Company has been destroyed by fire, with a loss estimated at from $3,000 to $5,000.

PAUL'S VALLEY.—The St. Louis capitalists who have been in the city recently looking over the local electric light plant have purchased the plant, it is said, and will at once add a gas plant.

IOWA.

MARSHALLTOWN.—It is stated that the Council has authorized the water and light committee to make repairs to the lighting plant; two new dynamos are needed.

LE MARS.—The Gas & Electric Development Company, of Philadelphia and New York, reports the sale of the Le Mars plant. The property was purchased by Mr. Bascom Parker, of Niles, Mich., who assumed control September 1. Extensive improvements will be made.

KANSAS.

HERRINGTON.—Charles F. Custafson, of Topeka, it is stated, has secured a franchise to furnish water, electric light and power to Herrington.

ATCHISON.—The Atchison Railway, Light & Power Company has amended its charter, increasing its capital from $300,000 to $900,000, and will build interurban lines to surrounding towns.

WEIR CITY.—The Weir City Light & Power Company has made a contract to furnish the branch line of the Pittsburg Street Railway Company with power. This extension will go to Scammon and other points.

ELLSWORTH.—Mr. Paul Reaume, owner, and Mr. Clarence Pohlman, superintendent, of the People's Electric Light Plant, have plans under way for making the Ellsworth plant one of the most modern and up-to-date in the West.

PITTSBURG.—The C. A. Burton Machinery Company has been awarded the contract for installing an electric light and power plant for this city.

TOPEKA.—A new corporation, the Topeka Edison Company, has been granted a charter by the Kansas State Board. This is the company, backed by the backers of the City Railway Company, which has bought out the Edison Electric Illuminating Company. The capital stock is $1,250,000, divided up into 12,500 shares of $100 each. The directors are as follows: B. E. Sunny, L. E. Myers, E. E. Wilson, George B. Caldwell, George H. Taylor, Frank G. Kelly, Albert M. Patten, C. R. Maunsell, Albert H. Priddy. The last four are Topeka people. Three trustees are named who hold 5,480 shares of stock in trust, but are not in the directorate of the new company. They are E. A. Potter, Jr., Theodore P. Bailey and F. R. Fenton, all of Topeka. The new light company will put in a large power plant and furnish current to the railway company.

KENTUCKY.

SOMERSET.—W. G. Hunter, of Somerset, has received the franchise for an electric light plant.

ASHLAND.—The Virginia Light & Power Company is reported incorporated, with a capital of $25,000, to construct an electric lighting system from Richmond, Va., to Ashland.

CAMPBELLSVILLE. — J. L. Atkinson, president of the Campbellsville Lighting Company, writes that the construction of the proposed electric light plant will be under the supervision of E. S. Kincort, superintendent, who will probably expend $5,000.

MAINE.

PORTLAND. — The Citizens' Water & Light Company has been formed. Capital, $230,000. President, C. E. McGlauflin; treasurer, H. L. Cram. Directors, as above and A. F. Pine, all of Portland.

BANGOR.—The Stanley Electric Manufacturing Company, of Pittsfield, Mass., it is reported, has closed a contract with the Bodwell Water Power Company, of Bangor, for eight 1,000-kw. generators and necessary switchboards, the cost to be about $75,000.

BIDDEFORD. — The Pepperell Manufacturing Company is to install an electric light plant to light both the Pepperell and Laconia division by electricity, instead of by gas, as at present. The plant will be installed this fall and be in working order for the winter days.

AUGUSTA.—The Kennebec Light & Heat Company has recently purchased a new three-phase generator. The new machine will be used for the purpose of generating the power that is to be used at East Winthrop, and for the Tayntor Company, at Hallowell, and probably the State House will also be lighted from this machine.

MARYLAND.

HYATTSVILLE. — A committee has been appointed to report on the construction of a municipal electric light plant. Harry W. Shepherd, chairman light committee.

BALTIMORE.—The Consolidated Gas, Electric Light & Power Company has advertised in the local papers the fact that since the great fire it has doubled its business in 16-c.p. lamp equivalents, and has tripled its power service in horse-power of motors connected. Mr. D. Barnett, formerly of New York, is the energetic manager of the system. The contract for the company's new Westport power house, to cost $150,000, was recently awarded to the Baltimore Ferro-Concrete Company.

ELKRIDGE.—A delegation from the First, or Elkridge, district of Howard County has been before the county commissioners to protest against any change in the method of lighting the village of Elkridge. The delegation brought a numerously signed petition. About a month ago a five-year contract was awarded to the Patapsco Electric Lighting Company, of Grays, Baltimore County, calling for 1,800-c.p. lights, the wiring to be completed and service begun October 1. The system now in use, supplied by the United Electric Company of Baltimore, furnishes arc lights of 2,000 candle-power. The petition claims that the same amount of money is required for fewer lights under the new contract.

MASSACHUSETTS.

LAWRENCE.—At the regular monthly meeting of the water board Superintendent Collins was instructed to ascertain the cost of installing and maintaining an electric lighting plant at the pumping station and report at the next meeting.

UPTON.—The Upton Electric Company has sent a letter to the local authorities declining to accept the conditions whereby the use of Upton's streets could be secured for the carrying on of electric lighting service. The selectmen gave the company privileges of location, provided the company would light Upton Town Hall free of charge while the contract was in force.

WALTHAM.—A new power house is in process of construction at Waltham. The building will be of concrete and steel construction, 153 feet in length, 100 feet wide and 35 feet high, with a boiler room at the rear at a lower level. When the building is completed three generator engines, now being built, will be installed; power will be supplied for electric lighting and for the street car service.

HOLYOKE.—The contract for the new power plant of the Holyoke Water Power Company has been awarded to Casper Ranger for about $150,000. The contract includes the building, the canal walls of granite, head gates of iron, and it is estimated about 1,000,000 brick will be required in addition to the other material. The house will be located near the Norman paper mill, and the excavations have been made. Mr. Ranger has already begun construction work.

HOLYOKE.—Manager Snow, of the municipal gas and electric department, has given out the annual report of the department required by the State Lighting Commission. In spite of reductions in the price of gas and tar, the returns of the gas department show a profit, although it is about $19,000 less than last year. The electric department receipts show a profit of $14,767.02. While this report shows a working period of a year, yet it is not the annual report made to the Mayor. The profits of the department for the year were $18,485.52.

MICHIGAN.

GRAND RAPIDS.—The Grand Rapids Edison Company is preparing to install a steam turbine.

GRASS LAKE.—The lighting proposition has been carried in this city by twenty-three majority. Work will be commenced at once on the new plant.

ROSE CITY.—James Monaghan and Frank G. Bell have secured a franchise to install a commercial lighting plant, the contract for which has been awarded to the M. B. Wheeler Electric Company.

GRAND RAPIDS.—The Grand Rapids Electric Light Company has been incorporated, with a capital of $15,000. Incorporators: Walter C. Winchester, W. C. Miller and E. A. Stowe.

PONTIAC.—Engineers McKean, Ball & Co., of Chicago, Ill., write that the general contract for constructing the plant of the Clinton River Power Company has already been let, but wire and supplies and arc lamps are yet to be purchased.

FLORENCE.—A. E. Edmonds and Rhinelander capitalists, it is reported, will construct a power plant to supply the cities of Florence and Crystal Falls with light, and operate an interurban line from Iron Mountain to Spread Eagle Lake.

CHEBOYGAN.—Dr. A. M. Gerow is promoting an enterprise to dam Pigeon River. He has the necessary flowage rights. The entire cost of the investment will be $350,000, the current delivered in Cheboygan, the transformer station included. The plant is to generate 8,000 horse-power. The head will be 75 feet.

SAGINAW.—The Rifle River Power Company has filed its articles of association. The company is organized to produce electricity for lighting, heat and power. Its plant will be erected on Rifle River in Arenac and Ogemaw counties. The capital stock is $2,000,000, all subscribed, $2,000 paid in. The stockholders are George Silsby, Frank E. Kleinfeld, Alvah E. Kendall and Edwin Stapleton, all of Saginaw.

DELRAY.—The Solvay Process Company has lighted the village of Delray since its incorporation. Its contract expires next April, and unless some arrangement is made the village will have no lighting system. Delray is to be taken into Detroit, and the Edison Illuminating Company has secured a contract with the Solvay Company for illuminating when the contract which compels the latter company to light the village expires.

GRAND RAPIDS.—The Grand Rapids & Muskegon Water Electric Power Company, owning flowage rights on the Muskegon River and the biggest power dam in Western Michigan, located near Big Rapids, has entered Grand Rapids for the purpose of supplying light and power for commercial purposes. The Muskegon Company already has the contract for furnishing power to the Grand Rapids & Muskegon interurban, and it has been reported that the new deal involves the furnishing of power also to the Grand Rapids & Holland interurban.

MINNESOTA.

MOUNT IRON.—This village is reported to have voted to install an electric light plant.

MINNEAPOLIS.—It is stated that bids will probably soon be asked for furnishing the city 1,000 electric lights and 2,200 gasoline lamps.

MISSOURI.

WAUSAW. — The proposition to issue $6,000 electric light bonds was carried at the recent election.

ST. LOUIS.—The Natural Power Company of this city has increased its capital stock from $30,000 to $60,000.

OWENSVILLE.—Work has been commenced on the power plant to be erected here by Peter Helling, of Gerald.

FARMINGTON. — The Farmington Electric Light & Ice Company will probably add shortly to its equipment an additional unit for the purpose of supplying a day circuit and heating service.

ST. LOUIS.—The General Fuel & Illuminating Company, of St. Louis, has filed a statement showing that it has increased its capital stock from $60,000 to $70,000, all the increase paid.

ST. CHARLES.—The city electric light plant is receiving a complete overhauling. The circuits are also being repaired. The question of moving the plant and consolidating it with the city water works plant is still in deadlock in the Council.

SIKESTON.—The Sikeston Ice, Light & Power Company has filed letters of incorporation, with a capital stock of $25,000. The incorporators are Charles D. Matthews, Jr., Edward C. Matthews, Joseph E. Armstrong, Reese B. Boyce and J. Handy Moore.

ST. LOUIS.—Paul D. Cable, president of the General Service & Development Company, announces that he has purchased from the West St. Louis Water & Light Company the lighting franchise obtained by it from St. Louis County Court several years ago, together with all its physical properties. If his plans are developed in full, farming by electric light may be witnessed in St. Louis County within the near future. He intends to light all the main country roads, and wires will be strung into the farmhouses, stables or fields, if so desired by the residents along the route. The franchise is a comprehensive one, giving to the owner the privilege to build in any part of the county.

ST. LOUIS.—In a letter that accompanied the Union Electric Company's proposal to illuminate the public buildings south of Washington Avenue, W. M. Powelson, general manager, declared that if the term of the contract were extended from one to ten years his concern could furnish the energy for 3¾ cents per kilowatt-hour. He recommended that the Board of Public Improvements consider the change. The contracts for lighting public buildings, both north and south of Washington Avenue, were let, the successful bidders being the Laclede Light & Power Company and the Union Electric Company. The former got the contract for the north and the latter for the south district. The Laclede Company's bid was 5½ cents and the Union's 5 cents per kilowatt-hour.

MONTANA.

VIRGINIA CITY.—The Butte Electric Light & Power Company is reported to have petitioned for a franchise to furnish this city with electric light and power.

BIG TIMBER.—The Big Timber Electric Light & Power Company, it is reported, has petitioned for a franchise for water works and an electric light system.

HELENA. — The Helena Power Transmission Company has awarded the first of a series of contracts, aggregating $1,500,000, for the building of a dam across the Missouri River near here to the Wisconsin Bridge Company, of Milwaukee. It is expected that the company will begin the transmission of electric power to Helena, Butte and Anaconda within ten months. About 20,000 horse-power will be developed, and this will be utilized chiefly in the Amalgamated smelters at Anaconda and in mining at points between there and Helena, as well as for lighting and street car purposes in the cities mentioned. The entire product of the present dam is used in the Helena smelters and Butte mines. Additional contracts have been let as follows: The S. Morgan Smith Company, of York, Pa., four pairs of main water wheels, to be constructed of cast iron, and each pair to have a capacity of 4000 horse-power; the Allis-Chalmers Company, of Milwaukee, for furnishing the auxiliary or exciter wheels. It is stated that the contract for the electrical machinery is yet to be let.

NEBRASKA.

ADAMS.—The town is negotiating with parties for the establishment of an electric light plant. The town will use street lights, and business men are taking commercial lights.

GRAND ISLAND.—The Mayor has been authorized to secure an electrical engineer to prepare and submit plans for an electric lighting plant for the city, to be operated in connection with the water works. Later bonds will be issued and the plant built.

NEVADA.

LOVELOCKS.—It is reported that the installation of an electric lighting plant is contemplated.

GOLDFIELD. — The Bishop-Nevada Electric Power & Lighting Company has been incorporated, with a capital of $1,000,000, for the purpose of constructing an electric plant on the Owens River, near the town of Bishop, to transmit power to Tonopah, Goldfield, and Bullfrog. D. Jones, of the J. Jones Exploration Company, may be able to give further information.

TONOPAH.—The Nevada Power Mining & Milling Company, C. M. Hobbs, manager, has contracted with the Allis-Chalmers Company for a Bullock 1500-kw., three-phase generator for use on its Tonopah transmission system. The original installation is well advanced, two 750-kw. National Electric three-phase generators having been ordered some time ago. The prospects for business have increased. Power will be transmitted nearly 100 miles.

RENO.—The Reno Power, Light & Water Company and the Washoe Power & Development Company have been secured by the Fleishhacker interests and ruinous competition in the lighting business at Reno prevented. The Hunter Creek Water Company and the Sparks Water Company will be included in the merger. It is understood that a new company will be incorporated that will probably be called the Union Power, Light & Water Company, and capitalized at $2,000,000. The Fleishhackers are heavily interested in the Truckee River General Electric Company, which supplies electric power for the Comstock mines at Virginia City, and in the American River Electric Company, with transmission lines from near Placerville to Stockton, Cal.

NEW HAMPSHIRE.

FRANKLIN.—Work is now under way on the new reservoir, to be used in connection with the city water system. Electric power will be used for pumping.

PORTSMOUTH.—The contract for the electric power plant at Freeman's Point has been awarded by the Publishers' Paper Company to the General Electric Company. Work will begin at once. This contract involves an outlay of more than $100,000.

LACONIA.—The Laconia Electric Light Company has begun furnishing power for the street railway. The lighting company has secured control of the Meredith plant, and wires will be run from The Weirs to that place before winter sets in. It is the intention of the new owners to use the Meredith plant as a reserve power, to be used as occasion demands. The latest acquisition to the plant is a 225-h.p. engine.

SHELBURNE. — An important deal has been consummated for a new water power plant. The contract has been let to Ward Brothers, of Berlin, for the construction of a dam across the Androscoggin, which at this point is 350 feet wide, and a power house 110x50 feet, the total cost being estimated at between $75,000 and $100,000. It is the purpose of the Berlin Electric Light Company to transmit electric power to Berlin, and it is expected that at least 1200 horse-power will be available from this new source. The power-house will be of concrete and will be fireproof.

PORTSMOUTH. — The Rockingham County Light & Power Company, of this city, which furnishes power for the light of the New Hampshire Company all over the southern part of the State, and also lights this city, has served notice through its counsel, Judge Samuel W. Emery, on Mayor Marvin and City Clerk Underhill that it has brought suit against the city of Portsmouth for unjust taxation of the company's plant in this city. The company was assessed on an appraisal of $451,250, which it claims is overvalued to the amount of $277,818.

NEW JERSEY.

NEWARK.—Morris R. Sherred, chief engineer, it is reported, is preparing estimates for a municipal lighting plant.

ATLANTIC CITY.—An ordinance has passed first reading in the City Council granting a franchise to the Atlantic City & Suburban Electric Company.

KEARNY.—It is reported that an agreement has been reached between the Public Service Corporation and the Lighting Commission on a two-year contract for lighting the streets.

PERTH AMBOY.—The City Council has granted a franchise to the Citizens' Electric Light & Power Company. The company will probably begin work on its plant at once. Engineers, Runyan & Carey, 122 Market Street, Newark.

NEW MEXICO.

SILVER CITY.—The City Council has granted a fifty-year electric light franchise to George T. Schmelzel and associates.

JARILLA.—R. G. Mullen represents a company which proposes erecting power plants along the Sacramento River for a mining camp at Jarillo.

ALBUQUERQUE.—The Union Gas & Traction Company has been incorporated, with a capital of $500,000, for the purpose of constructing and operating gas, oil, electric and water works plants and systems; to operate a system of pipe lines, wires, etc., for the transportation of gas, oil, electricity and water; to own and develop clay, sand, cement and other lands and properties; to operate steam, electric and cable street cars or traction lines. Incorporators: C. H. Pattison, Kansas City,

NEW YORK.

CAMDEN. — The contract for constructing a power house for the municipal electric light plant has been awarded to J. A. Raymond. The building will be ready to receive machinery October 1.

NEW YORK. — The Suffolk County Lighting Company has been incorporated, with a capital of $50,000. The directors of the company are George MacDonald, Charles A. Hickey and William H. Morgan, all of New York City.

CLYDE.—The Clyde Gas & Electric Company has been incorporated to take over the Clyde Gas & Electric Company; capital, $25,000. The directors are P. W. Summers, Ithaca; G. S. Sheppard, and W. T. Morris, Penn Yan.

ROCHESTER. — The Niagara Falls Electrical Transmission Company, of Niagara Falls, N. Y., has applied to Mayor Cutler for permission to erect poles and wires and to construct conduits in the streets, alleys and public places of the city, and to transmit and sell electric power and light.

STILLWATER.—Flood & Sherrill, of Sandy Hill, have secured the contract to construct a concrete dam across the Hudson River at Stillwater, at a cost of about $16,000. About 600 to 800 cubic yards of rock will be excavated. The dam is to provide power for the Hudson Valley Railway and to the mills.

HERMON.—The Hermon Electric Light Company has been organized, with a capital stock of $15,000. J. H. Cullimore, Sr., is president and manager, and W. G. Popple, secretary and treasurer. The plant operates on a 12 o'clock schedule, and supplies 800 16-c.p. lamps and one arc lamp. The main equipment consists of a gasoline engine unit.

LITTLE FALLS.—The P. B. McCaghey Company has been organized by W. J. Berrigan, of Little Falls; J. E. McCaghey, of Sandy Hill, and others. The company has secured contracts from the Paul Smith's Hotel Company to construct two electrical power plants, one at Union Falls, Clinton County, and the other at Franklin Falls, Franklin County.

ROCHESTER.—It is stated authoritatively that the Niagara Falls Electrical Transmission Company, which has asked for a franchise in Rochester, has no connection with the Niagara, Lockport & Ontario Power Company, and that the latter company does not contemplate seeking franchises in Rochester and Syracuse. The Niagara Falls Electric Transmission Company has as its president Mr. Frederick Nicholls, of Toronto. Its vice-president is Frank A. Dudley, of Niagara Falls.

UTICA.—Work has been started on the pump house of the Hudson River Electric Power Company, north of the new power plant on the river bank. The first of the permanent turbines will arrive and will be put in position about October 1. Those now in use are only temporary, and their combined capacity is 2000 kilowatts. The first of the permanent generators to be erected will supply this power alone, and as it will be placed on an extra base in the plant, the work of establishing it will not interfere with the operation of the other turbines.

NORTH CAROLINA.

STATESVILLE, at a recent election, voted $20,000 for water and for improving the electric lighting system of the town.

GREENSBORO.—The Greensboro Electric Company has installed four 300-h.p. boilers, thereby doubling the capacity of its plant in the city.

CONCORD.—The town of Concord has contracted with the Murray Iron Works, Burlington, Iowa, for a 225-h.p. Corliss engine; with the Allis-Chalmers Company for a 150-kw. alternator, and with the Adams-Bagnall Company, of Cleveland, for fifty arc lamps.

FAYETTEVILLE.—It is proposed to expend about $20,000 on the municipal electric light plant and line extension, the work to include the installation of two boilers, 300 horse-power, one or two engines; one 250-kw. alternator and two 120-kw. generators. W. T. Jones, superintendent.

CHARLOTTE.—The Southern Power Company, Charlotte, is making contracts to furnish electric energy to manufacturing plants, and the latest contract is with the Southern Cotton Oil Company at Charlotte, for about 300 horse-power, beginning with the incoming cotton season. The newest development, which is at Great Falls, on the Catawba River, will be completed in eighteen months, according to estimate, and there will be available at that point 60,000 horse-power.

OHIO.

ROSEVILLE.—The Clay City Electric Company has been incorporated, with a capital stock of $10,000, for the purpose of operating a light and power plant.

CLEVELAND.—M. A. Bradley has been granted a permit for the erection of a $48,000 power house at the northwest corner of Ontario and Noble streets.

CARROLLTON.—The Carrollton Electric Company, composed of U. C. DeFord and J. C. Ferrall, has disposed of its plant and property to a stock company for a consideration of $15,000.

READING.—George Hornung, consulting engineer, 612 Johnston Building, Cincinnati, writes that bids will be received October 15 for the construction of a new electric light plant for Reading, to cost about $30,000.

SALEM.—A deal of considerable importance was consummated here by the sale of the entire plant and holdings of the Salem Electric Light & Power Company to E. E. Beam, of Cleveland, and S. D. Gilder, of Cincinnati.

YOUNGSTOWN.—Press reports state that a combination of the railway and lighting companies in and near Youngstown is to be known as the Mahoning & Shenango Railway & Light Company. It will have a capital of about $10,000,000 and control about thirty corporations. Murray A. Verner, of Pittsburg, Pa., is reported interested.

MIAMI. — The Maumee Valley Electric Company is making preparations for the extension of its operations on both sides of the river between the city line and Maumee and Perrysburg, including the two named towns. The company operates the power plant near Miami, that was originally used to furnish electricity for the Maumee Valley Belt Line. It is owned by the Detwilers and George G. Metzger. A franchise will be asked from the councils of Maumee and Perrysburg and an effort made to light every house on both sides of the river between Toledo and the two towns up the Maumee. Wires are now being strung to many summer homes just beyond the city limits.

TOLEDO.—The principal features of the franchise asked by the Central and East Side heating and lighting companies are: Companies to give city bond, Central $25,000, East Side $15,000, to insure good faith and completion of plans in eighteen months; rate for lighting to be 9 cents per kilowatt-hour; city has right to use all of either company's poles or conduits without charge; city reserves right to change prices for heating every five years, lighting every ten years; franchise to run twenty-five years; the Board of Public Service is vested with authority to compel either company to extend its service to any reasonable location. Charles S. Ashley, president of the Central Heating & Lighting Company, it is stated, has announced that extensive improvements are to be made in the company's lighting plant, which is located in the Meredith Building.

OKLAHOMA TERRITORY.

WEATHERFORD.—The contract for the erection of the new power house has been awarded to A. O. Campbell, of Oklahoma City.

SHAWNEE.—Willis Fertig, of Titusville, Pa., has been granted a franchise for an electric light plant here. He will also operate and extend the present electric street railway.

PAWHUSKA.—The Pawhuska Electric Light, Ice & Water Company has filed articles of incorporation stating the capital stock to be $25,000. J. W. McLoud, of Little Rock, Ark., and B. Erick, of Fort Wayne, Ind., are the promoters of the project.

OREGON.

DRAIN. — The Skelley Lumber Company is about to apply to the Town Council for a water and light franchise.

PENNSYLVANIA.

WILLIAMSPORT. — The Lycoming Electric Company has taken out a permit to erect a new power house, to cost about $75,000.

CAMDEN.—The Wyoming Gas & Electric Company has been formed to operate and maintain gas and electric lighting plants; capital, $15,000. Incorporators: John A. MacPeak and others.

SINKING SPRING. — The Cumru Township Electric Light & Power Company has been formed, with William F. Krick, of Sinking Spring, as president, to furnish electric light in Sinking Spring and Shillington. Capital, $5,000.

GREENCASTLE.—The Greencastle Light, Heat & Power Company (Harry C. Hollinger, Philadelphia, treasurer) has been incorporated, according to reports, with a capital of $10,000, to furnish light, heat and power to Greencastle.

CONNELLSVILLE. — A deal just completed makes a change in the ownership and management of the Interstate Electric Company of Connellsville. On account of a press of duties as superintendent of transportation of the West Penn Railways Company, J. W. Brown, who organized the company, and Frank Zimmerman have sold their stock to J. M. Fisher and Charles O. Moser, who were electricians for the company.

HUNTINGDON.—The Juniata Water & Water Power Company is reported incorporated, with offices at Huntingdon and Philadelphia. The company has purchased property for the erection of a hydro-electric power plant in Warrior Ridge Gap, and construction will, it is said, be started as soon as plans can be prepared. The cost of the proposed plant will be about $1,000,000, and power will be transmitted to Huntingdon, Tyrone, Altoona and other towns in this vicinity. S. L. Brumbaugh, president, Philadelphia.

YORK HAVEN.—The York Haven Water & Power Company has placed a force of men at work to construct the poles for the line by which it will transmit electric power to Middletown, Harrisburg, Pa., and other points in Dauphin and Lancaster counties. Agents of the company are still engaged in securing rights of way for the construction of the proposed line, and it is said that the corporation will soon have all of the necessary rights so that it can dispose of its power across the river. Preliminary work is now being done for the laying of the cable beneath the Susquehanna River from the York Haven plant to a point on the Lancaster County shore, where a terminal station will be built.

RHODE ISLAND.

MOOSUP.—The Consolidated Railroad Company is proposing to buy the Packer power privilege at the Quinebaug Bridge, a few miles west of Moosup, with a view to building an electric power plant to furnish light and power for the tramway, and also for the villages of Plainfield, Wauregan, Central Village and Moosup.

SOUTH CAROLINA.

COLUMBIA.—The Hatton Shoals Power Company has been organized at Anderson with a capital of $150,000.

GREAT CATAWBA FALLS.—Three hundred men are already at work on the immense water power development of the Southern Power Company at Great Catawba Falls in upper South Carolina. The entire developments along the Catawba will represent an outlay of perhaps two million dollars.

SPARTANBURG.—T. D. Lawshaw, of the firm of Lawshaw & Lawshaw, Spartanburg, S. C., is superintending the developing of a hydro-electric transmission on Meherrin River, at Emporia, Va. From 3000 to 5000 horse-power will be generated and will be used for operating a cotton mill, city lighting, etc.

SOUTH DAKOTA.

GROTON.—The Groton Light, Heat & Power Company (C. D. Jones, secretary), proposes constructing a central heating plant. H. E. Miles, engineer, Groton.

PLUMA.—Phillips & Bartlett, of Deadwood, are stated to have secured the contract for erecting a power house at Pluma for the Consolidated Power & Light Company; probable cost, $20,000.

SIOUX FALLS.—The Queen City Electric Light & Power Company has been incorporated at Pierre with a capital of $300,000. Incorporators:

H. J. Hanford, Chicago, Ill.; P. Curtis, Norwalk, O.; W. G. Mack, of Sioux Falls, and others.

TENNESSEE.

KNOXVILLE.—Bids are to be received, according to reports, for lighting the streets on three, five, seven and ten-year periods.

CLINTON.—The City Council is reported to have passed on first reading the ordinance granting William B. Crawford, of Oliver Springs, a franchise for water works and an electric light plant.

BRISTOL.—Following a meeting of the directors of the Bristol Gas & Electric Company, it was announced that the General Electric Company has purchased a large interest in the properties and franchises of the local company which owns all the gas, electric and street railways in this city and Bristol, Va.

GREAT FALLS.—The Great Falls Power Company, proposing a big water power development near Nashville, Tenn., has asked for an extension of time limit of the franchise and will likely be favored. Already sufficient money has been promised, it is said, for the construction of the electric plant which the company proposes to build, and from which power will be furnished to Nashville.

CHATTANOOGA.—Local press reports state that the plans for the lock and dam and the power plant of the Chattanooga-Tennessee River Power Company, to be constructed at Hales bar in the Tennessee River, at a cost of about $3,000,000, are now ready for inspection of contractors at the office of the U. S. Engineer, in the Loveman Bldg. Bids will probably be called for at once. John Bogart, consulting engineer, 16 Exchange Place, New York, N. Y.

KNOXVILLE.—The board of directors of the Knoxville Power Company has held its annual meeting. Plans for the proposed power plant to be erected on Little Tennessee River have been discussed. The following officers were elected at the meeting: President, Charles H. Treat, New York City; vice-president, John T. Wilder, Knoxville; secretary, John F. Barry, New York City; assistant secretary, L. M. Parker, Knoxville. The Knoxville Power Company will expend $3,500,000 in building the plant.

TEXAS.

GONZALES.—The Citizens' Electric Light & Power Company has increased its capital stock from $5000 to $10,000.

EAGLE PASS.—The Texas-Mexican Electric Light & Power Company has increased its capital stock from $20,000 to $40,000.

EL PASO.—W. A. Hawkins, of El Paso, and associates, are considering the matter of erecting electric power plants on the Sacramento River in New Mexico.

GREENVILLE.—Extensive improvements are to be made to the city electric light and power plant of Greenville. A proposition to sell the city plant to parties who propose to construct an electric street railway system here is being considered.

FORT WORTH.—At the recent election held for the purpose of voting on the question of granting a franchise to Judge Armstrong to establish an electric light, power, gas and heating plant, the people voted in favor of granting the franchise.

BAY CITY.—By order of the court the Bay City Ice, Light & Power Company's plant will be offered for sale to the highest bidder by Special Commissioner Judge W. C. Carpenter early in September. This plant is very finely equipped, having cost in the neighborhood of $40,000. It would no doubt have been a money-making institution from the start, but through over expenditure on buildings and fine machinery it became deeply involved and was forced into the hands of a receiver. During the past few months it has been showing nice profits and as the town grows and as new territory is opened up by the Brownsville road now building it will prove to be a profitable investment.

UTAH.

VERNAL.—The City Council has granted a franchise to G. H. Seth for an electric light, heat and power plant.

EPHRAIM.—The city has recently installed a 500-horse-power Pelton water wheel operating under 640-foot head for running the generator which furnishes the city lighting.

OGDEN.—L. B. Spencer, of Ogden, has filed with the state engineer, at Salt Lake City, an application for a water right on Ogden River. He intends to construct a power plant to furnish both power and light in Ogden.

RICHFIELD.—A. J. Paulson, of Richfield, has filed with the state engineer, at Salt Lake City, an application for a water right on Sevier River. It is proposed to install a power plant capable of developing 450 horse-power.

SALT LAKE CITY.—J. H. Bigger and J. E. Hill have applied for permission to develop power for electrical purposes from American Fork Creek. They propose developing 950 horse-power for electric lighting and for working machinery in the American Fork mining district.

VERMONT.

RUTLAND.—The annual meeting of the Rutland City Electric Company has been held. These directors were elected: S. M. Hamill, A. H. Jackson and H. M. Francis, of Schenectady, N. Y.; F. M. Butler and George S. Haley, of Rutland. Mr. Hamill was elected president, Mr. Jackson vice-president, Mr. Francis treasurer, Mr. Butler secretary and Mr. Haley general manager.

READSBORO.—Plans are under way for the erection of an electrical power plant on the Deerfield River, north of the east portal of the tunnel. A charter for the new company has been secured from the State of Vermont, under the name of the Deerfield River Power Plant Company. Among those interested in the project are W. S. Morton, of Hartford, Conn.; James H. Roraback, of Canaan, Conn., and Faxon Bowen, of Readsboro, Vt. The plant will be located near Readsboro in Vermont, and will cost about $1,000,000.

VIRGINIA.

LURAY.—Preliminary surveys have been made for developing the Shenandoah River near Luray, and about 500 horse-power is found available. D. G. Strickler, F. G. Grave and other parties in Luray are interested.

WASHINGTON.

CASHMERE.—It is reported that F. C. Barnum, of Cashmere, is endeavoring to obtain a franchise to erect an electric light plant here.

SUNNYSIDE.—The question of constructing water works and an electric light plant is reported under consideration here. The probable cost is $15,000.

ARLINGTON.—Thos. Moran is reported to have secured a franchise for a light and water system, the power to be developed from the falls of Jim Creek.

EVERETT.—The Mayor has been directed by the City Council to appoint a committee to investigate the possibility of establishing a municipal electric light plant.

SEATTLE.—The Stanley Electric Manufacturing Company has sold a carload of lighting transformers to the city of Seattle for use in connection with the municipal lighting plant.

TACOMA.—The City Council Committee on fire and water has recommended that the arc circuit, which in the report of the City Engineer is estimated to cost $5,000, be installed immediately.

REARDAN.—The Reardan Light & Power Company, it is reported, has been incorporated with a capital of $5,000 to engage in the light and power business. Incorporators: Frank Bradley, John Fields, John Rayman and others.

PROSSER.—The Prosser Falls Land & Power Company has started to build an addition to its dam across the Yakima River at this point, which, it is expected, will prevent a recurrence of the present low water next year. The stream at this point is now flowing but 200 second-feet, the smallest in its history, and if the dam had not been put in last year Prosser would now probably be without water works, irrigation or electric lights.

WISCONSIN.

PHILLIPS.—The Phillips Light, Water, Heat & Power Company petitioned for a franchise.

SHEBOYGAN.—The Sheboygan Light, Power & Railway Company is figuring on plans for extensions and new suburban lines.

MENASHA.—It is quietly rumored that this city is to have a municipal lighting plant. While there has been no public announcement it develops that certain officials have been putting in labor and research along this line for the past year.

MILWAUKEE.—The County Trustees are discussing the question of providing for a central heating, lighting and power plant and extending the city water mains to the Wauwatosa institutions. Alderman Stiglbauer's resolution providing that $60,000 be set aside from the water fund to purchase a site for a municipal lighting plant, was unanimously adopted by the finance committee.

CANADA.

PEMBROKE.—The Pembroke Light, Heat & Power Company has been formed to acquire water power on the Black River, for the purpose of adding to the present electric light system.

NAPANEE.—W. A. Grange, town clerk, states that plans and specifications have been prepared by R. S. Kelsch, New York Life Building, Montreal, Que., for the proposed municipal electric light plant; probable cost, $35,000.

MEXICO.

CITY OF MEXICO.—Modesto R. Martinez, on behalf of Andres Matienzo, has secured a concession to utilize the waters of Atoyac River in the State of Puebla for power purposes.

ALLENDE.—A new electric light and power plant is to be installed at Allende. The organization of the company was promoted by Enrique Guerra, of Ciudad Porfirio Diaz, State of Cohuila.

CITY OF MEXICO.—Parties, whose names are not stated, have applied to the Federal Government for a concession to establish an electric power plant on the San Andres River in the State of Zacatecas.

CHILPANCINGO.—The Belgian syndicate, which recently purchased the Jeronimos waterfall, situated on the Pedrenas River, in the State of Guerrero, is preparing to erect a large electric power plant at the fall. The power will be transmitted to cities and mining camps of the State.

TAMPICO.—The Luz Electrica de Tuxpam is the name of a company which has been organized at Tuxpam for the purpose of installing and operating a new electric light and power plant. Among those interested in the enterprise are Luis Montoto Carsi, Antonio Alvarez, Manuel Perez, Santos Gonzales and Felix Costilla, all of Tuxpam.

CITY OF MEXICO.—It is reported that the Mexican Power Company, with an authorized capital of $10,000,000 operating under a New Jersey charter, has been organized and is preparing to utilize the water power of three rivers in the State of Mexico near Toluca. It will furnish electric power to this city, estimated at 90,000 horse-power.

CITY OF MEXICO.—The Mexican Light & Power Company will erect fifteen station and storage buildings along its power transmission line between the main power plant at Necaxa and the City of Mexico. These stations will be used for the accommodation of the linemen and watchmen who will constantly patrol the line and for the storage of materials.

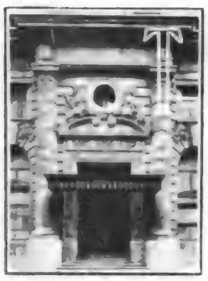
CITY OF MEXICO.—It is learned that a strong company is being formed in London and Berlin for the purpose of installing a large electric light and power system in the City of Mexico. It is reported that representatives of those back of the company have been in the City of Mexico securing contracts for the furnishing of power and that enough of these have been secured to insure the financial success of the enterprise. The names of the parties interested have not yet been made public.

American Electrician.

Vol. XVII. New York, November, 1905. No. 11.

POWER AND LIGHTING EQUIPMENT OF A MODERN HOTEL.

ENGINEERING FEATURES OF THE GOTHAM AT FIFTH AVENUE AND FIFTY-FIFTH STREET, NEW YORK CITY.



THE Hotel Gotham, which has recently been completed at the southwest corner of Fifth Avenue and Fifty-fifth Street, New York City, at an expense of nearly three million dollars, ranks among the most elaborate and costly of the numerous handsome hotels in New York City. Like the larger portion of the buildings of this class which have been recently erected, the Gotham is provided with its own mechanical and electrical equipment, which corresponds with the complete arrangement for the comfort, safety and convenience of its guests. The building is 21 stories high, and needless to say, fire-proof throughout. As is usually the case where ground space is very valuable, the mechanical equipment is of necessity compactly arranged in the basement, reminding one of machinery aboard ship, so that suitable photographs for purposes of illustration were difficult to obtain.

The general layout of the plant is shown in the plan view, Fig. 2, which is drawn to a scale of 1/16 inch to the foot. A view of the main engine room is given in Fig. 1. Steam is generated in five 200-h.p. boilers of the Manning type. These are connected by 7-in. bends to a 12-in. header running the length of the boiler room. A 12-in. high-pressure steam main, connected at right angles to this header, runs into the engine room and supplies the engines and elevator pumps. After leaving the engine room, the high-pressure steam main continues as a 6-in. main for feeding auxiliary apparatus. Valves are provided in the large main and header to shut off any of the boilers desired, any of the branches, and in addition, a 6-in. gate valve is provided where the main changes to 6 inches in size. A 4-in. branch is taken off the 6-in. main and connects through a 2-in. by-pass with the exhaust pipe. A pressure-reducing valve is arranged on this main to reduce the pressure from 100 pounds to 5 pounds; this valve is provided with a by-pass. A 2-in. connection with a gate valve on the same leads from this 4-in. branch into each of the two 300-h.p. feed-water heaters.

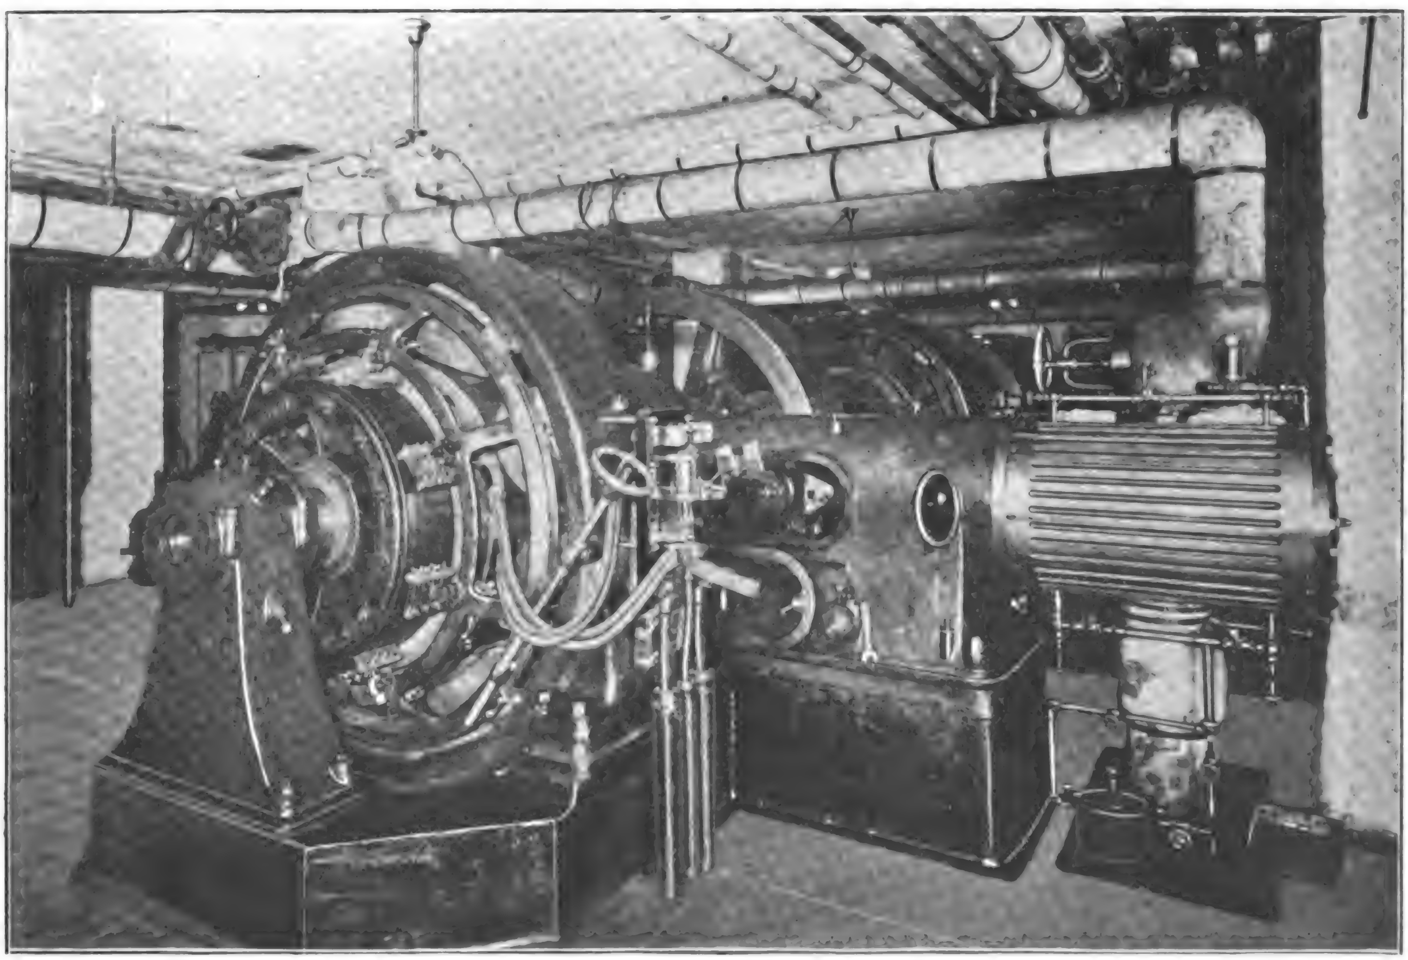


FIG. 1.—ENGINE ROOM OF THE GOTHAM HOTEL.

Full-sized branches are run from the main to each of the steam pumps and to each of the electric generating sets. The

branches to the latter sets are 6 inches in diameter and each is provided with a valve close to the main and with a throttle valve at the engine. The piping of the boiler feed pumps is cross-connected for both generator and hand control.

The main exhaust pipe is 12 inches in diameter and is located in a trench in the engine room rising with a long bend beside the muffler tank. The connections into this tank are through a tee with a long bend inside the tank and with a long bend to the by-pass connection. These connections are provided with the necessary gate valves. The exhaust from the boiler feed pumps enters this 12-in. main before it reaches the muffler tank. From the muffler tank the exhaust extends to the bottom of the ex-

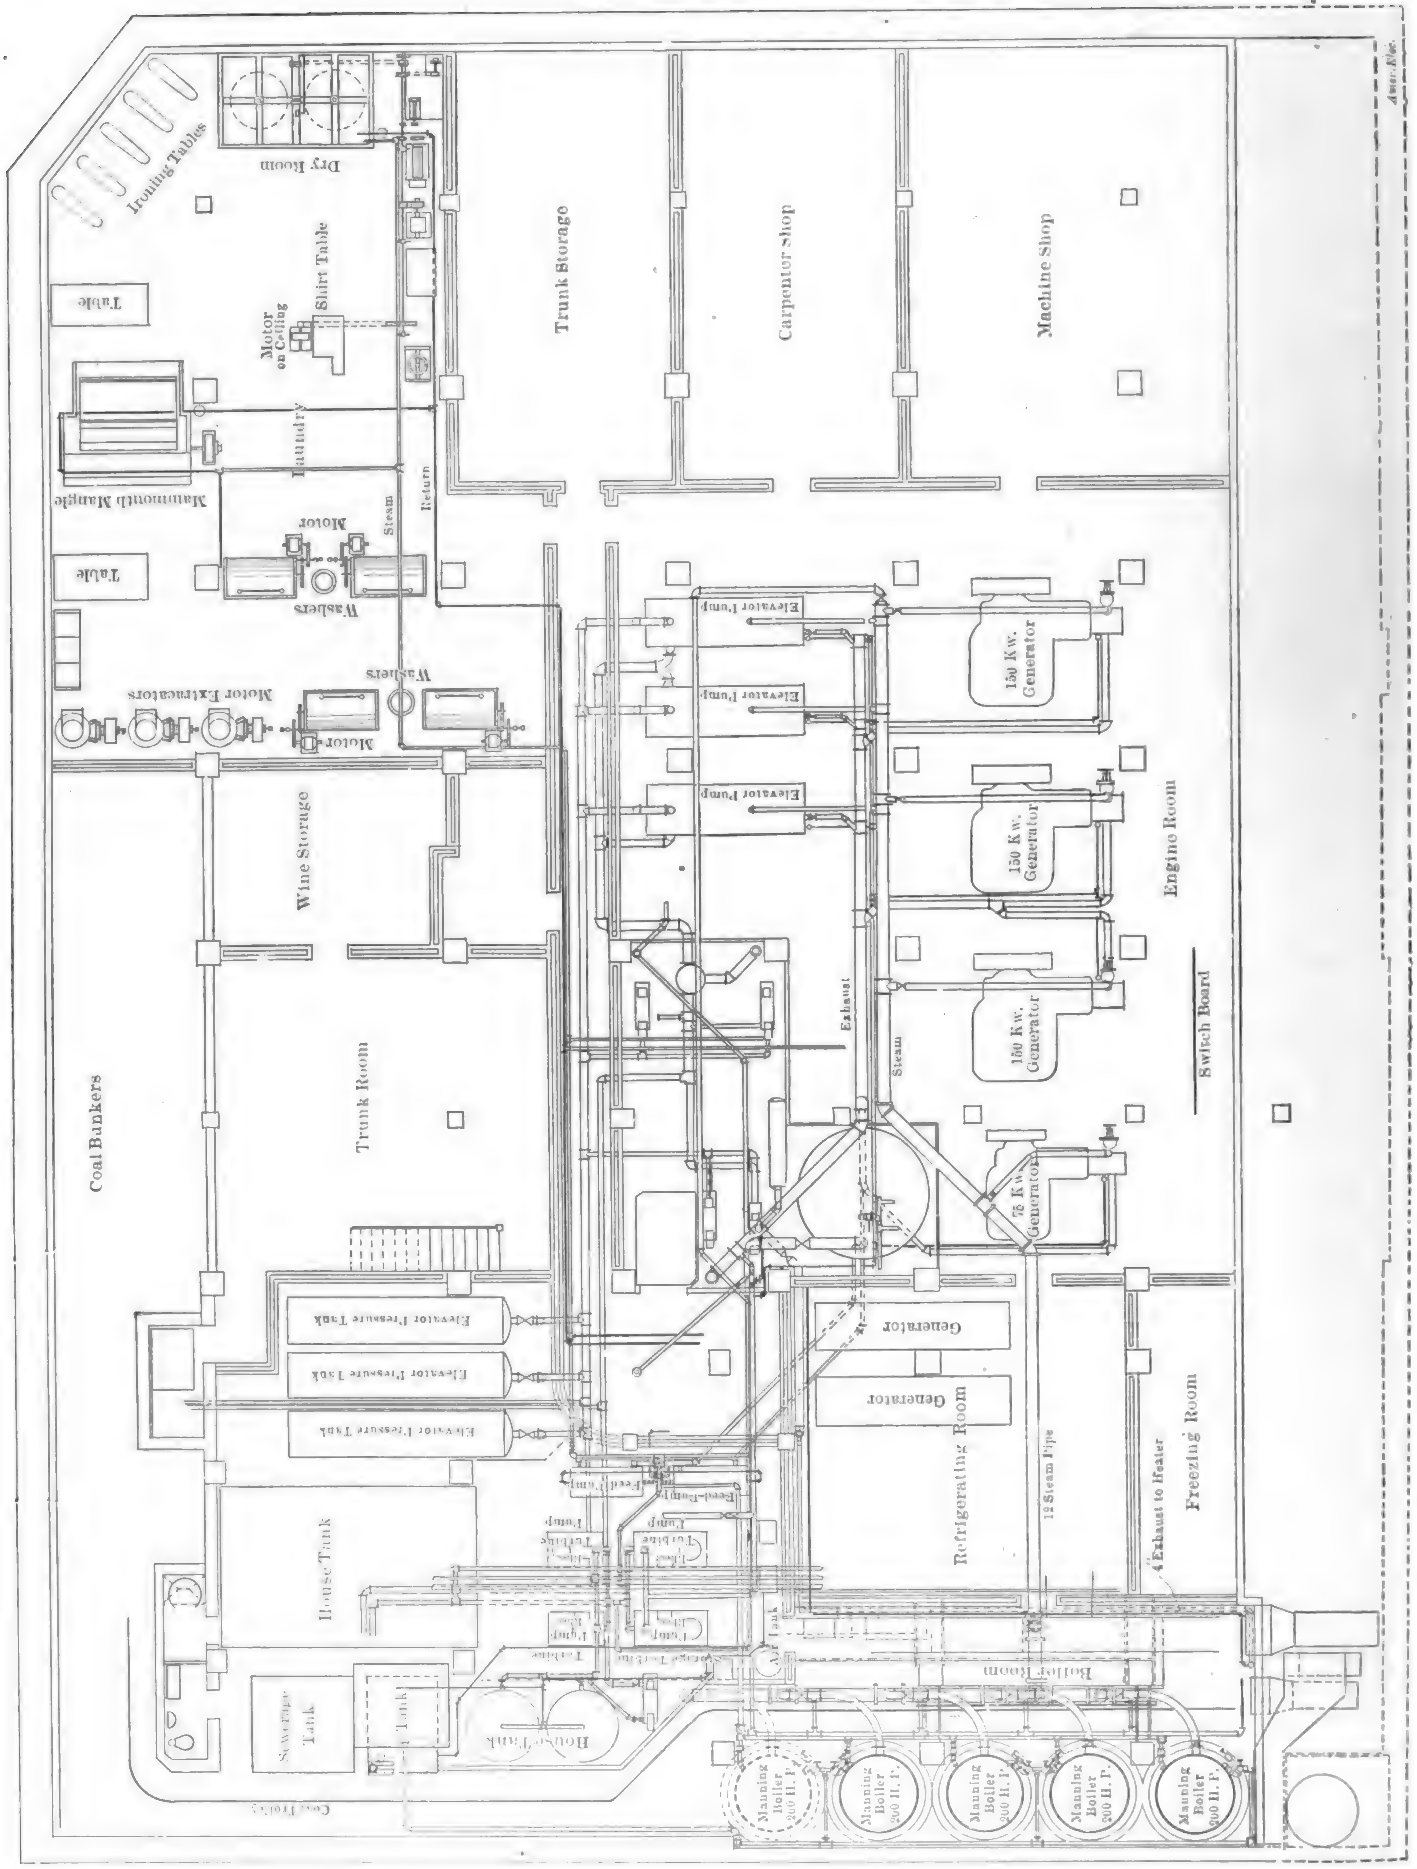

FIG. 2.—PLAN VIEW OF BASEMENT OF THE HOTEL GOTHAM, SHOWING THE MECHANICAL LAYOUT.

haust riser with a drop leg on the same, and a 12-in. supply branch is connected to this line feeding two 10-in. branches to the two feed-water heaters and one 10-in.branch with a flange connection to the header of the refrigerating system generators. The vertical portion of the exhaust riser is of light-weight wrought-iron pipe and is anchored at the cellar, the ninth and twentieth floor levels and provided with two sleeve expansion joints. At the twentieth floor level there is a tee and a gate valve for the heating system, together with a back-pressure valve and exhaust head. The exhaust pipe runs for the main part in trenches where it is supported on graded rollers, with a drip connection at the point where it rises to the exhaust muffler.

A 1½-in. drip main runs beside the exhaust pipe to collect the oily drips from the engines and pumps. At the muffler tank this drip main is enlarged to 2 in. and a branch leads into the oil chamber and into the return chamber of the muffler tank; from here the main extends into the drip tank. A 2-in. drip line is installed on the cellar ceiling, with ½-in. branches and traps to receive the condensation from all steam jackets used in the kitchens. This main runs into the return chamber of the muffler tank. A 2-in. main also runs on the cellar ceiling from the laundry and discharges into the return chamber of the muffler tank. This main is provided with ¾-in. branches to all steam jackets and traps in the laundry. In addition, there is a 1½-in. main carried beside the exhaust pipe with ¾-in. branches and traps to take care of the clean condensation from the engines and from the high-pressure steam line. This main discharges into the return chamber of the muffler tank. All of these drip mains are provided with valves on all branches.

FIG. 3.—MOTOR-DRIVEN MANGLE.

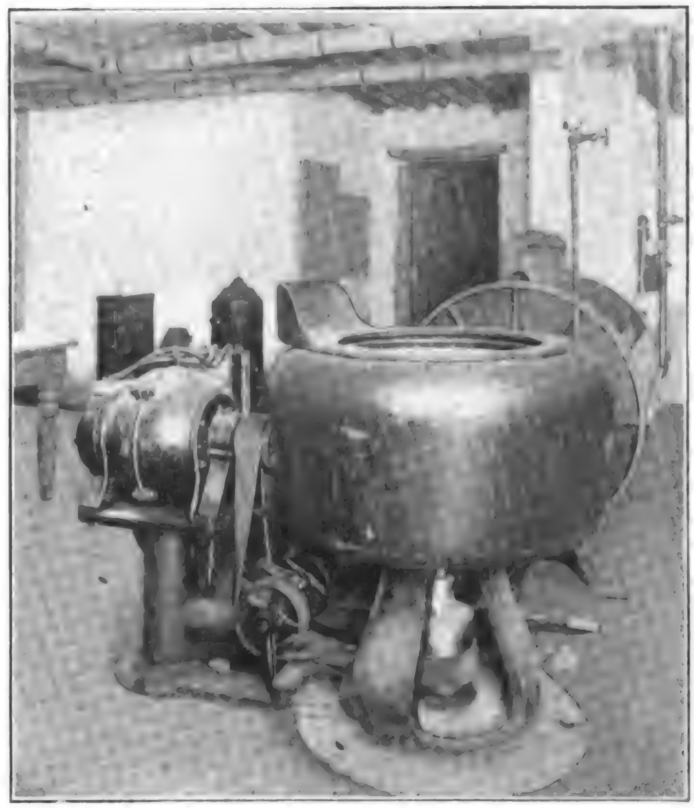

FIG. 4.—MOTOR-DRIVEN EXTRACTOR.

Water for boiler feeding purposes is taken from the city mains. A 4-in. main runs from the return chamber, through a pump governor, to the boiler feed pumps, and a similar sized main is connected with the suction tank. From the discharge side of the pumps a 4-in. main runs in front of the boilers with a 2-in. connection to each boiler, this connection being provided with a gate and a brass check valve. All of the valves used in connection with the feed-water piping are of the gate type and the piping is of galvanized iron, erected with valves and flanges so as to be readily taken down.

FIG. 5.—WASHING MACHINERY IN LAUNDRY.

Two and one-half inch blow-off branches lead from each boiler into a 3-in. main of galvanized iron connecting with the blow-off tank. From the blow-off tank a 4-in. connection leads to the sewer outside of the building, with two tees and a gate valve between and a gate valve on each tee branch for a by-pass to the sump pump. A vapor pipe from the blow-off tank is connected into the safety valve pipe. Each of the safety valves is connected to a vapor line discharging into the smoke stack, and a ½-in. branch leads from the same opening into the boiler room. The sump pumps are connected with suctions running to the

blow-off tank, into the sump, into the drip tank, and with a branch connected to the

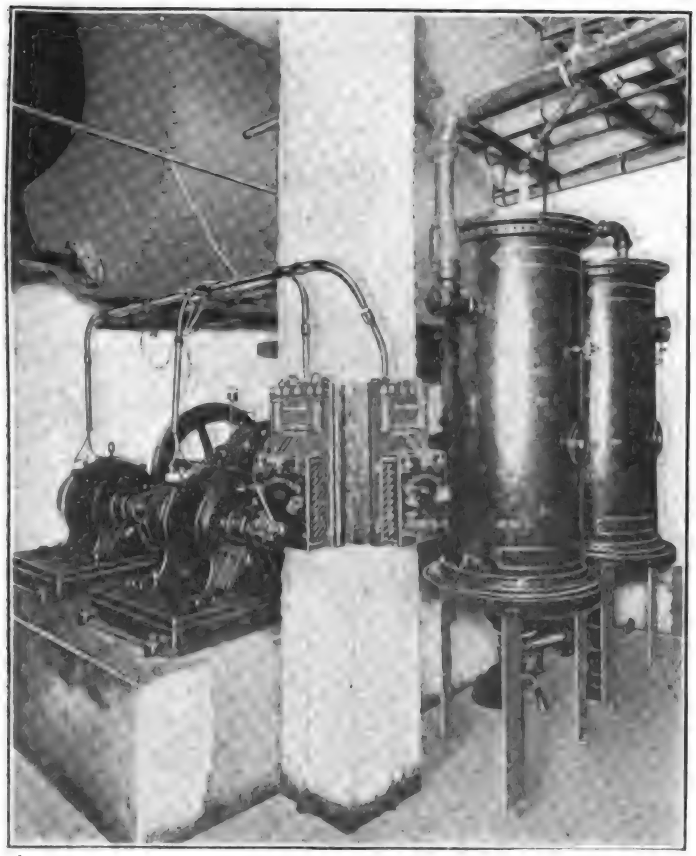

FIG. 6.—VACUUM CLEANING EQUIPMENT.

sewage tank. Each of these branches is 3 inches in diameter and provided with a gate valve, the suction into the sump being also provided with a mushroom strainer. A 4-in. galvanized-iron pipe runs from the discharge side of the blow-off tank to the sewer. The muffler tank is of special design, combining a muffler tank, grease extractor, return tank and feed-water heater, fitted complete with the necessary diaphragm, baffle plates, water trays, cast-iron flanges, manholes, water columns, etc. All the steam piping, heaters, tanks, etc., with the exception of the sewage tank, are covered with molded sectional heat insulators containing 85 per cent. of magnesia with canvas jackets and Russia iron bands.

In the engine room are located four electric generating sets, as well as the switchboard for the light and power service. The generators are all compound-wound machines and were furnished by the Sprague Electric Company of New York. Three of these are of 160 kilowatts capacity and the other is of 75 kilowatts capacity. They all generate direct current at a potential of 250 volts. The generators are direct-connected to non-condensing engines built by the Ball Engine Company, of Erie, Pa. The light and power service of the hotel is operated on the two-wire system, 225 volts being used for both lights and motors. The motors are used chiefly for driving pumps, fans and laundry machinery and in the kitchen.

The switchboard is of polished white Italian marble two inches thick. The board is made up of five panels, enclosed in a bronze frame, the back being encased by a screen. The two generator panels each contain two double-pole circuit-breakers, two single-pole knife switches for equalizer connections, two recording wattmeters, two rheostat handles for generator rheostats on the back of the board, two ammeters and one voltmeter. There is also provided a multiple voltmeter switch for ground detector service. High and low-pressure steam and air gauges are also mounted on the switchboard. These correspond in finish to the other instruments. No fuses are placed on the board, a separate fuse panel being provided in the rear for that purpose.

Provision is made for thirty main feeder circuits, besides four generator circuits, but five of the feeder circuits are at present blank. The circuits are arranged in the following order: Service power, basement power, cellar and basement power, engine room lights, restaurant and palm room, ice room lights, boiler room and pumps, café, service lights, bakery, service lights, kitchen, laundry power, ice room power, pump room power, roof fans, apartments (west), hall (all night), apartments (east), reading and ball room, pantry heaters, public hall, apartments (north), restaurant and palm room.

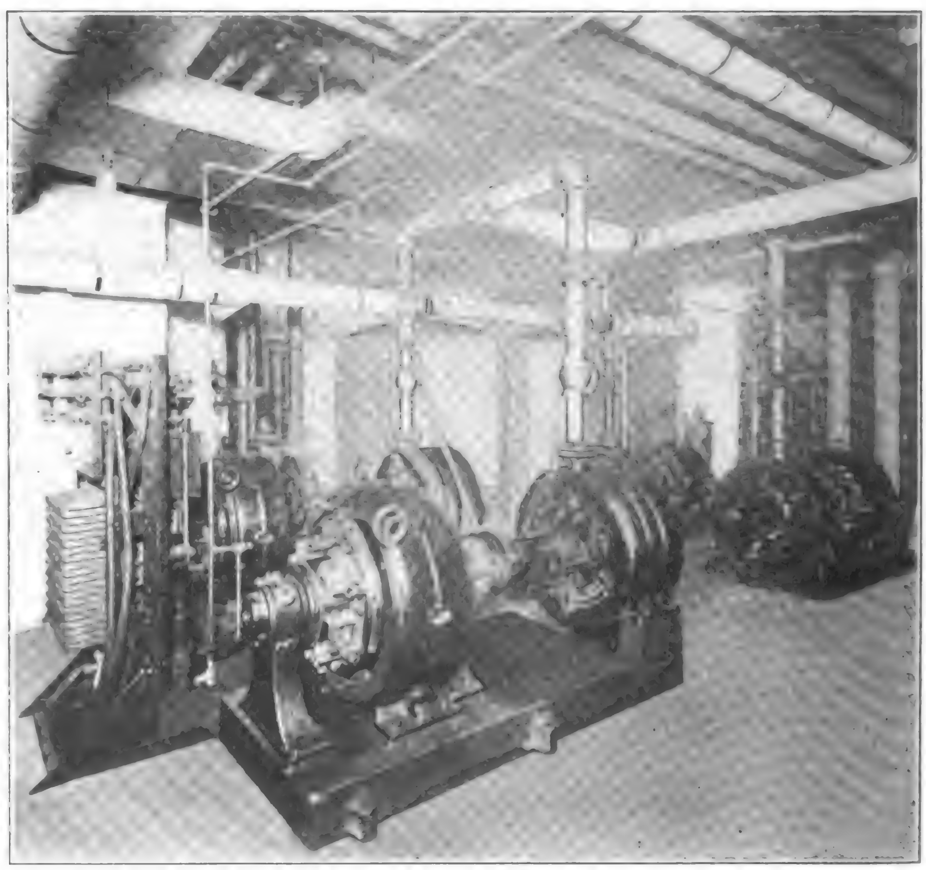

FIG. 7.—MOTOR-DRIVEN CENTRIFUGAL PUMPS.

So far as the wiring system is concerned, the hotel may be conveniently divided into three distinct portions—the working or service portion, the public portion, and the apartment or bedroom portion. The latter comprises usually everything above the first or second floor, the basement and cellar being devoted to service, by which is meant the kitchen and serving rooms, storage rooms, machinery, etc. The public portion includes the café, restaurant, palm garden, ball rooms, etc. The kitchen and serving rooms are effectively lighted by means of cluster fixtures and drops, while the engine, boiler, pump and other machinery rooms are lighted by drops and ceiling clusters. The public portion is, for obvious reasons, sumptuously furnished and artistically lighted, effect rather than efficiency being sought. The lighting of this portion is on a larger and more splendid scale than the rest of the hotel. The restaurant is lighted by ceiling and bracket fixtures with individual lights for the tables, attachment plugs being provided for that purpose. The ball room and palm garden have, in addition, very ornate candelabra fitted with miniature lamps. The rooms of the upper floors are lighted by side and ceiling outlets, the average rooms containing from eight to ten lights. The corridors throughout are lighted by ceiling outlets. Over six thousand 235-volt incandescent lamps are connected up, the major portion of these being 16 candle-power, while smaller candle-power lamps are used for decorative purposes.

The motors used for driving the auxiliary machinery are all of Sprague make. There are two house and two fire pumps, which are of the Worthington centrifugal type, and these are driven by two 20-h.p. and two 40-h.p. direct-current motors respectively. Two 3-h.p. motors are used to drive the sump pumps. A vacuum cleaning system is installed for cleaning the carpets, etc., throughout the building. This apparatus is shown in Fig. 6 and is driven by two 7½-h.p. round-type motors through silent chain drive. A 2-h.p. motor is connected to a shaft in the kitchen, operating ice cream freezers. Numerous other kitchen utensils are driven through motor drive. In the laundry, views of which are shown in Figs. 3, 4 and 5, there are four 2-h.p. motors driving washing machines, three 3-h.p. motors driving extractors, one 5-h.p. motor connected to a main line shaft operating irons, and one 3-h.p. motor operating a mangle. There is also a motor driving a collar and cuff machine, starch mixer, drying fans, etc. There are numerous fans about the building, all of which are motor-driven. These are given in the accompanying table:

Location.	Size of Fan.	Style.	Motor.
Kitchen	90-in.	Exhaust.	4-h.p.
Laundry	60-in.	"	1-h.p.
Billiard room	50-in.	"	1-h.p.
Restaurant	90-in.	"	4-h.p.
Ball room	70-in.	"	3-h.p.
Dumbwaiter shafts	3, 60-in.	Cone.	3, 2-p.h.
Store room	48-in.	"	1-h.p.
Locker room	24-in.	Exhaust.	¼-h.p.
Basement	18-in.	"	⅛-h.p.
Office	18-in.	"	⅛-h.p.
Kitchen range	24-in.	"	¼-h.p.
Roof	7, 42-in.	Cone.	7, 1-h.p.
Laundry	60-in.	"	2-h.p.

All the wiring for electric lights, call bells telephones, and for power is enclosed in "Loricated" conduit. The panel boards throughout the building are of ¾-in. white marble encased in iron boxes provided with lugs for the attachment of the face panels and doors. They have in all cases copper conductors secured on the faces with Noark fuse carrier combination and name plates designating the circuit. The boards controlling the lights on the first and second floors are provided with knife switches. Boxes are provided of such a form as to leave a space on the back of the board for the wiring where the depth of the pocket admits; elsewhere the wire is passed out at the top and bottom with room on the sides of the boxes for the circuits. Flush switches are used to control individual lights, and for surface work in the cellar and basement double-pole Hart switches are used.

The General Building & Construction Company, of New York, were the general contractors for the building and the Contractors' Electrical Company, of Brooklyn, had charge of the electrical work; the Baldwin Engineering Company, of New York, were the contractors for the steam and heating equipment. Mr. C. K. Van Etten is the chief engineer of the Hotel Gotham to whom we are indebted for courtesies extended in the preparation of this article.

British Gas Engines.—It is estimated that one-third of the gas made in Great Britain is used in driving engines.

INCREASING PROFITS OF A CENTRAL STATION.

BY GEORGE E. WALSH.

The utilization of exhaust steam for heating purposes at the central station in small towns and cities has in the last year or two been tried experimentally, and the results justify under certain conditions this method of economizing in by-products. The distribution of steam through street mains and pipes for heating offices and private residences has developed rapidly, and today there are upward of 500 companies in the field of district steam heating. Customers who use this outside steam supply have the advantages of cheaper rates than when the boilers are located in the building, a steadier supply of steam for heating, increased safety from fire dangers, no dust or ashes from coal or other fuel, and no engineers or firemen to look after. So far as the district steam supply companies are concerned they effect a saving in cost of labor, boiler insurance, cost and kind of fuel, and general depreciation of plant.

What applies to the strictly steam supply companies is equally true of electric light and power plants where steam heating is looked upon as a by-product. In order to secure fair profits without overcharging customers for electric light and power, it is quite essential in towns of 20,000 or more inhabitants to utilize every possible economy for securing profitable results. The utilization of the exhaust steam for heating purposes has only lately attracted the attention of central station engineers.

The central station company has usually greater advantages in supplying steam for heating purposes than the independent steam plant. The electric light company has business relations with numerous customers which makes it comparatively easier to present a proposition for supplying steam heat for their houses and offices. Some electric light companies which have entered this field have recently been forced to increase the size of their plant in order to meet the demands upon it, although six months ago their electric output barely paid a profit on the investment.

Steam exhausted from the engine can be economically distributed to customers for heating purposes and the consensus of opinion among steam and electrical engineers in the district heating field is that exhaust steam should be sold on the basis of live steam. Even at the cost of producing live steam and distributing it through the mains, the price will be much lower than it would cost individuals to produce it. The cost of producing the live steam must be determined and fixed and meter charges made accordingly.

Some central station companies can save this waste steam by simply installing the underground mains and piping the buildings of customers. In the construction of new central stations engineers are making designs with reference to this combination of lighting and heating, and in the near future nearly every electric light plant will likewise be a steam heating station for the distribution of heat to customers. The service is growing so rapidly in favor in small towns and cities that owners of old plants are studying the situation with a view to changing their machinery to secure this new source of profit.

In old plants where the engines operate as condensing units, the condensers are detached during the heating months, and during the summer months they are operated condensing. Arrangements are also made so that the engines can operate part condensing and part non-condensing. When the full amount of steam is not required the changeable nature of the plant will thus insure greater profits. In some stations where the installation of engines is not sufficient to supply all the steam needed for customers, additions to carry the load have proved profitable. That is, there is a profit in supplying steam heat alone, and where the exhaust from the electric light plant is not sufficient it is economical to increase it. The enlargement of the plant so that live steam can be supplied where the exhaust is insufficient has frequently demonstrated the economy and value of this phase of the business.

The methods of charging for steam heat supplied are various, but the meter system is the only satisfactory one both to consumers and producers. By estimating the cost of production of live steam it is possible to establish a rate that will prove profitable. By using meters the charges are automatically adjusted to the different classes of buildings. The varying demand for steam heat during the different hours of the day can soon be ascertained by the curve sheet plotted from the reading of the meters. In this way it is possible to estimate in advance the comparative demand for steam at different hours so the use of all the engines can be regulated without waste of energy.

The cost of evaporating 1,000 pounds of water at the station, including cost of coal, labor and fixed charges, will vary in different parts of the country, but the price charged to consumers should cover this and leave a fair margin for profits. Not all companies charge according to meter reading, but by the number of square feet of radiation. A fixed annual price is made by this system for each square foot of radiation installed, with usually a different charge made for direct, indirect and economizing coil radiation.

The People's Gas & Electric Company, of Defiance, Ohio, has a hot water circulating system installed in connection with the electric light plant with charges to consumers based upon the square feet of radiation. Nearly 2000 feet of two-inch main pipes are laid underground by this company, and upward of 2500 feet of four-inch pipe. In this plant the exhaust steam from the engine is carried to an open heater where the water is heated to 160°. An ordinary boiler feed pump is used for circulating the hot water which is distributed to houses from two to three thousand feet distant. The charges are based upon the number of square feet of radiation installed in each house, and the returns from the

exhaust steam have proved very profitable.

The Lima & Toledo Traction Company, of Ohio, has likewise installed a steam heating plant in connection with its central station, and the utilization of waste steam for heating has added materially to the profit of the enterprise. This company bases its charges upon the cost of live steam, and supplies it to customers at meter or fixed annual charges, at rates which leave a good margin for profit. Where the charges are based upon a fixed annual rate per thousand cubic feet of space heated, it has been found from experience that a careful differentiation in buildings and rooms must be made. The character of the rooms to be heated is very important. Where the exposure to cold winds is on the north side, the amount of steam required to heat them is nearly double that demanded for rooms with a southerly outlook. Moreover, a modern fire-proof building is apt to be proof against dampness and winds, and rooms in it require far less steam to heat them. Thus it may be that unless the character of the buildings and rooms are carefully considered, the fixed annual charge per thousand cubic feet of space to be heated will leave no margin for profit. It is moreover an incentive on the part of the consumer to waste steam. When a fixed charge is demanded the consumer has no reason to economize in the use of steam. The radiators are kept hot at all times of the day and night, and if the heat is too great all the windows are thrown open. The waste of heat is thus enormous and often unnecessary. Again there is the uncertainty of our seasons to consider. An open winter would make the charges just the same, and the same amount of steam would be wasted. The gain would be to neither consumer or producer. Where charges are made according to the square foot of installation, the tendency of builders and consumers is to reduce the amount of radiation to a point where unsatisfactory results are obtained. To decrease the fixed charges the installation is often made insufficient, and the complaint is that the steam service is not satisfactory.

It will appear from these varying conditions that the meter system of charging is the most satisfactory for both parties, and where the rate agreed upon is reasonable it results in profits of a substantial nature. This of course presupposes the basing of charges upon the cost of producing live steam and not upon what the exhaust steam may seem to be worth. Considered purely as a by-product central station managers have in the past sold steam on this basis and found in the end that it proved unprofitable. The cost of installing the mains and pipes, and the additional consumption of fuel to keep up the supply at certain hours of the day, increases expenses so that the by-product may become a source of trouble and loss rather than of gain.

The heating season in our Northern States extends from seven to eight months, but during only about half this time will the full capacities of the plant be demanded. Where the exhaust steam just equals the demand of consumers there is large profit in the work; but the periods when the exhaust steam is not sufficient must be considered. It is often necessary to run an independent engine to supply live steam to meet the requirements on very cold days or in the early winter evenings. The electric lighting is essentially a night load, but the highest peak is reached early in the evening or late in the afternoon of winter days. This is likewise the period when the greatest demand exists for steam for heating. It is often impossible to supply the two with the engines of the central station installed simply for the lighting load. The important question is to ascertain just when the conditions will warrant the enlargement of the plant by adding an independent engine for carrying the extra load. This engine may not be needed more than four or five months in the year, and the long period of its idleness must detract greatly from its value as a money-making machine.

A great many electric light companies operating by water power have installed engines for distributing steam heat to the different parts of the buildings of the plant. Such engines are used at times to carry part of the electric lighting load, but as a rule the engines are not in use a good part of the year. Where the plant is a large one this extra engine is found profitable, and in some cases it has been used for supplying district steam heating for other buildings in order to prevent rivals from entering the field. Where a neighboring plant or large building installs its own steam heating plant, it is very apt to furnish its own light as well. By anticipating this the electric companies have shut off private competition in electric light.

Indeed, it looks very much as if the electric companies must come to adopting this double work, so popular is steam heating becoming. The large office buildings and plants which depend upon electric light and power consider seriously the question of operating their own electric light and heating plant. The problem is only half solved when electric light and power are sold to them at a minimum of cost. The heating of the building must come up for serious attention. By supplying both electricity and steam heating to its customers, the electric light and power company gives added satisfaction and secures double returns on the investment.

While a central station plant can earn money out of exhaust steam for heating residences and offices in winter, the question of utilizing the power in the summer months has caused not a little bother and a good deal of practical experiment. With the day load in summer very light, the power of the engine should be utilized in some other economical way. A number of small central station plants supplying electric light for public and private use have in the past few years sought to extend their field by combining steam heating in winter and the operation of refrigerating and ice manufacturing plants in summer. Ice making and artificial refrigeration are summer loads, and the steam from the boilers which are used as auxiliaries in winter can be turned to profitable use in operating ice machines in the hot months. By combining the two industries the engines need be left idle only a very little of the time. The possibilities in this direction are not so limited as they may appear. A good many cold storage plants are operated only in the warm season, usually about four to six months in the year. The work of supplying steam for distilled water and for manufacturing ice or artificial refrigeration is sometimes problematical, for the cost of live steam furnished from boilers that are left idle most of the year is very high.

An electric light plant in Rochester which used exhaust steam for heating residences in winter enlarged its capacity by the installation of two extra boilers which furnished live steam when the demand was unusually heavy. Ultimately it was expected that the new boilers would be needed for the electric light business as the business increased, but until needed for that purpose the boilers were employed for furnishing live steam to customers for heating. The profits of this feature of the business proved so large that it was necessary to make another addition to the plant.

The question of utilizing these boilers in summer puzzled the engineers and managers for some time. The idleness a good part of the year seemed like waste. The managers tried to make arrangements to operate cold storage plants with their live steam, but owing to its peculiar location this seemed impossible. After a good deal of experiment and study it was decided to start a small ice-making plant near the central station. This was experimental, and the venture was carried on a small scale. But after one season's operation the success of the plant was evident. The ice was sold by contract to a local ice distributor, and the extra boilers were kept in profitable service all the year. No attempt was made to manufacture ice in winter, for the steam was then all needed for heating purposes.

Another electric light plant at Columbus, Ohio, has sought to combine refrigeration and steam heating in another way to utilize exhaust steam at the central station. Underground anhydrous ammonia and brine pipes were laid in such a way that in the winter time they could be used for supplying steam for heating purposes. So far this experiment has indicated success, but the question of general depreciation of the underground lines when used in this double capacity is one that cannot be answered immediately. There appears, however, a new field for development by which central stations can make use of their exhaust and surplus live steam by the combination of steam heating and refrigeration. As every factor that saves money must be considered it is quite important that careful attention should be given to these new fields.

ENGINE FRICTION AND LUBRICANTS.

BY R. T. STROHM.

The available power of a steam engine is the difference between the indicated horse-power and the friction horse-power. Consequently, to increase the delivered horse-power without correspondingly increasing the indicated horse-power, it is necessary to reduce the friction in the engine. This friction will exist wherever two surfaces come into sliding contact, and the amount of friction will depend altogether upon the condition of the rubbing surfaces and the pressure with which they bear against one another.

In the ordinary engine the main points at which frictional resistances occur are at the main shaft bearings, at the crank-pin, at the cross-head pin, along the guides, in the stuffing-boxes of the piston rod and valve stem, between the eccentric strap and its sheave, between the valve and its seat, and between the piston and the cylinder. There will be friction at the numerous smaller pins and in the governor connections, as well as wind resistance to the motion of the fly-wheel, but these latter may be neglected in view of the major points already mentioned.

In order to devise means whereby friction may be reduced, it is essential that its nature, cause and effect be understood. As to its nature, it is simply a resistance to

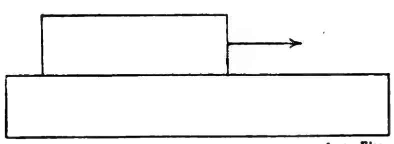

FIG. 1.

the motion of one body in contact with another. It is caused by irregularities in the rubbing surfaces. Take, for example, two cast-iron blocks having their contiguous faces planed and scraped accurately so as to be as nearly true planes as possible. If these blocks be placed as in Fig. 1 and the upper one be drawn across the lower, it will be found that there is considerable resistance to the motion, in spite of the fact that the surfaces had been made as flat and smooth as mechanical art would permit. This resistance is due to friction, and it is evident that even extreme precautions in preparing the rubbing surfaces have not sufficed to eliminate friction.

If, now, the blocks in Fig. 1 were cut lengthwise in a plane at right angles to the surfaces in contact, and the line of contact of the two surfaces thus exposed were viewed through a powerful microscope, it would appear somewhat as shown in Fig. 2. That is, instead of showing as a straight line, indicating perfect contact of both surfaces at every point, it would appear as two very irregular lines touching at various points, indicating that the surfaces are full of minute hills and hollows.

The cause of the resistance to motion of one block upon the other now becomes apparent. Many of the small projections or hills on one block fit into the depressions or hollows in the other, so that when the upper one is moved these ridges interlock, and thus resist the moving force.

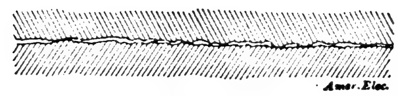

FIG. 2.

If these indentations are deep and the number of projections which fit into them are sufficiently great, the resistance offered may be sufficient to prevent any relative motion. Usually, however, the reverse occurs; that is, one block slides upon the other and the ridges are torn loose from their respective surfaces, this action being accompanied by the generation of heat.

The effect of friction, then, is threefold. First, it causes a resistance. Second, it wears and abrades the touching surfaces. Third, it causes the generation of heat. In the case of the steam engine, all three effects are undesirable. The resistance decreases the useful output of the engine, as has already been shown. The wear due to abrasion requires tightening of the brasses or packing and shortens the life of the engine. The heat generated may become of sufficient amount as to cause the brasses to grip or seize the pin, may melt out babbitt bearings, or harden packing so as to cause it to score the rod. Hence, the extreme desirability of reducing friction to a minimum.

Friction is reduced by the use of lubricants which may be divided into three general classes, known as fluid, plastic and solid lubricants. The first class includes all oils. The second class comprises the greases. The last class includes such solids as have been used for lubricating.

The theory of the action of a lubricant is very simple. In connection with Fig. 2 it was shown that frictional resistance is due to the interlocking of the ridges on the rubbing surfaces. The lubricant prevents this interlocking by filling up all the hollows and forming a very thin layer between the two surfaces, so that they touch only at very few points, where the ridges are higher than the average. For perfect lubrication, the lubricant should form a film between the surfaces that will prevent any contact whatever. But this is a condition scarcely realizable in practice. There will always be more or less contact of the surfaces, resulting in a corresponding degree of wear.

Applying these statements to the steam engine, it is evident that the first requirement for the reduction of friction losses is the selection of proper lubricants, and the second is the proper application of these lubricants to the rubbing surfaces. Inasmuch as the subject of cylinder and valve lubrication is so extensive and important as to warrant treatment in a separate article, lubricants for engine bearings alone will be considered here.

Much has been written concerning the selection of lubricants for given conditions. It is rarely the case that the selection of the best lubricant can be made off-hand. By far the most satisfactory method is to try various lubricants until one is found which gives good results, and this grade should then be demanded for future use. Nevertheless, there are a few fundamental rules governing the selection of a lubricant by which it is possible to narrow the field for any given set of conditions to a single class of lubricants.

For small engines in which the pressure on the bearings is comparatively light and the speed fairly high, a light mineral oil will be found to answer the purpose. For heavy pressure and high speed a heavy mineral oil should be used. If the pressure is heavy and the speed comparatively slow, then a very heavy oil, or a grease, should be employed. For ordinary machinery having no excessive bearing pressures, a fairly heavy mineral oil is generally used.

To be of value, a lubricant must contain no grit of any character. The presence of foreign matter of this nature will cause cutting of the bearing and of the journal, and will result in heating and probable seizure of the bearing. The test for grit particles is not elaborate. If a drop of oil or a bit of grease be well rubbed between the thumb and forefinger, or between the palm of one hand and the finger of the other, the presence of gritty matter may be readily detected.

Very often dirt will get into oil through carelessness. For the engineer to be certain, therefore, that the oil in his tank is clear and free from dirt, he should see that each new supply of oil, upon being emptied into the reservoir, is strained. The apparatus necessary is very simple and of trifling cost, and may save future trouble with hot bearings.

Since it is the function of a lubricant to form a layer or film between two surfaces so as to hold those surfaces apart, it follows that in order to do this successfully the lubricant must have body or cohesion enough to prevent its being squeezed out by the pressure. A very thin lubricant is, therefore, used where pressures are extremely light, and a very thick one where pressures are extremely heavy.

Now, it is plain that if the lubricant fills the depressions in the journal and in the bearing, and the former turns while the latter remains stationary, the particles nearest the journal will move at a velocity corresponding to that of the journal, while those nearest the bearing will be practically at rest. Slipping must occur, then, somewhere between the two surfaces. In ideal lubrication, all slipping occurs between the particles of lubricant which form the film, although actually there is some contact of metal and metal. In a bearing, then, there is some friction due to the rubbing metals and some due to the rubbing of the oil particles. The latter may be termed fluid friction, and it is much less in the case of a thin oil than in the case of a heavy, viscous one, while it always forms by far the smallest percentage of the total friction in a bearing. It is, therefore, advantageous to use a lubricant no more viscous than is absolutely necessary to prevent its being forced out from between the surfaces. Oth-

erwise, there will be unnecessary loss of power due to extra fluid friction.

Again, the lubricant used must not be volatile, that is, too easily vaporized under the effects of heat. If this should be the case, there would be danger of its becoming so thin when warmed by the friction of the bearing, that it could be forced out by the pressure. At the same time, rapid evaporation would increase the oil consumption without rendering any additional service in friction reduction. On the other hand, ordinary degrees of coldness ought not to thicken the oil appreciably. This is a thing that will happen if the oil contains paraffin to give it body.

The lubricant must also be free of all tendency to dry and become gummy. Should it possess any such properties, the probability is that the oil holes in the oil cups, the channels in the bearings, and the very film itself, would become clogged, under which conditions no oil could be fed to the bearing. A lubricant may readily be tested as to its tendency to gum, by putting a few drops on a clean piece of glass and allowing the whole to stand exposed to the air for some time.

Oils used as lubricants are derived from three sources. First, from the distillation of crude petroleum, such being known as mineral oils because of their mineral origin. Second, from the fatty tissues of various animals, these being known as animal oils. Lard oil, sperm oil and tallow oil are examples of this class. Third, from the nuts or seeds of various trees or shrubs, such oils being termed vegetable oils, because of their vegetable origin. As examples of this class may be mentioned olive oil, palm oil and castor oil.

For the lubrication of general machinery, mineral oils and animal oils hold the field, the vegetable oils being employed less rarely. In steam engine lubrication, mineral oils are used almost exclusively, though in some cases a compound lubricant is made by mixing a small percentage of animal oil with mineral oil. The disadvantage of animal and vegetable oils is that they are subject to decomposition under the effects of heat, with the liberation of acids which will attack metals and cause corrosion. Consequently, it is advisable to use straight mineral oils wherever possible, since they cannot decompose, and contain no injurious acids.

Under the heading of plastic lubricants come the various kinds of greases. These are usually made by mixing oils and fats in various proportions until the mixture has the consistency of lard. However, for engine lubrication, a grease must not be selected indiscriminately. Those greases which are mere mechanical mixtures of cheap oil, paraffin and fatty oils have a high friction coefficient in themselves and are corrosive when decomposed. The proper kind of grease to use on engine bearings is that which is produced by chemical combination of oils and fats. These have no chemical action on metals used for bearings, and will not become rancid or spoil, even though they are kept for a long time.

The solid lubricants are graphite, mica, sulphur and soapstone. All of these have been used in the lubrication of engines, but the first is by far the most common of the four. It is not to be supposed, either, that these solid lubricants are to be used alone on a bearing. The best results are obtained by using them in conjunction with oil. The mixing of graphite, soapstone, mica or sulphur with oil forms a lubricant which is found to be of inestimable service in cases where a pin or bearing has run hot, since it enables the engine to be kept in motion and at the same time reduces the temperature of the bearing. When it is remembered that a complete shutdown of an engine in a plant, for a sufficient length of time to cool and readjust a bearing, may mean a loss running into hundreds and thousands of dollars, the value of a lubricant which will permit continued service without ill effects, becomes apparent.

The action of graphite as a lubricant in connection with oil is peculiar. Being a solid, it becomes pressed into the irregularities of each surface, and thus brings each nearer to a condition of perfect smoothness. Consequently, the oil film between the surfaces need not be so thick. And, since it requires a greater pressure to squeeze out a thin film than a thick one, a less viscous oil may be used, resulting in a smaller amount of fluid friction.

The amount of oil may also be reduced, since the graphite fills up all the cuts and scratches and forms an exceedingly smooth glaze on each surface, possessing a low friction coefficient.

The solid lubricants mentioned are mineral in their nature, and care must be observed to obtain them in a pure state, free from earth or grit of any character which would cause unnecessary friction, heating and abrasion.

ELECTRICAL EQUIPMENT OF THE KEYSER VALLEY SHOPS OF THE LACKAWANNA RAILROAD.

The Keyser Valley shops of the Lackawanna Railroad, situated in Keyser Valley near Scranton, Pa., have been designed to take care of the freight equipment, including all repairs and upkeep on both wood and steel cars, and are fitted to do new work also on an extensive scale. The plant, which has recently been placed in operation, ranks among the most complete and up-to-date railroad shops in the country. The buildings are equipped throughout with motor-driven tools and labor-saving appliances and are provided with an abundance of natural and artificial light.

The plant comprises nine large buildings of brick and steel construction. The area covered by the buildings aggregates six acres, while the total floor space aggregates 225,000 square feet, of which 217,500 square feet are in cement. The entire electrical equipment of the shops is of General Electric make. In the power house are one 100-kw. and two 300-kw., three-phase, 60-cycle, 480-volt generators; each of which is direct-connected to a Ball & Wood engine. There are in addition one 30-kw. steam-driven exciter unit and a motor-driven ex-

places. In addition to the tabulated equipment, motor-driven fans are installed for the heating system of the plant and for exhausting shavings from the planing mill,

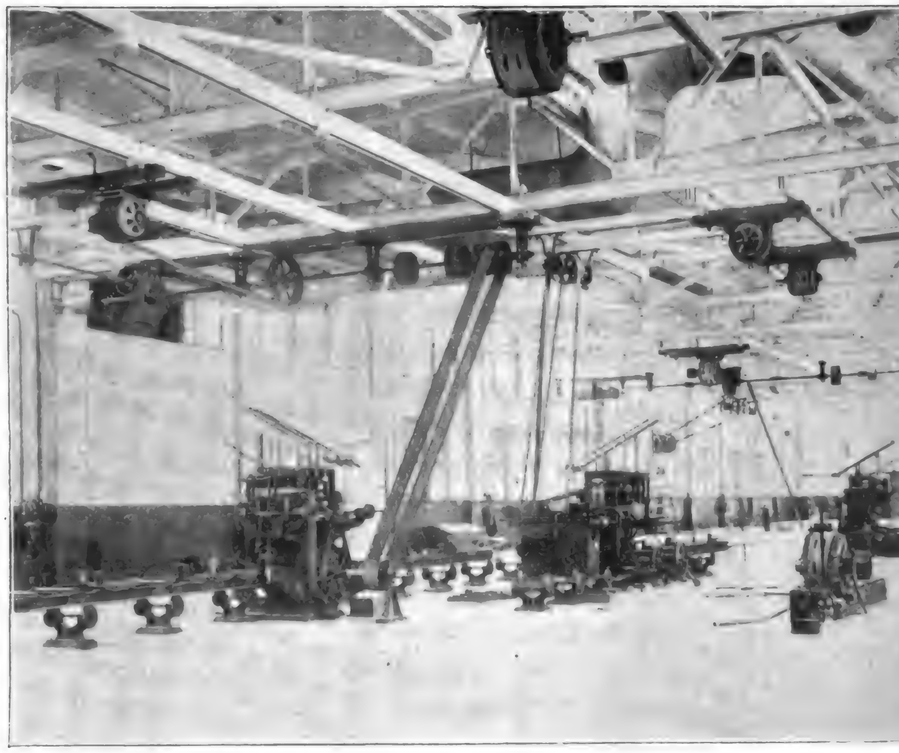

FIG. 5.—MOTOR APPLICATIONS IN PLANING MILL.

and motor-driven blowers are installed in the smith shop.

The lighting scheme for the various shops is presented in Table 4. In cases where arc lamps are staggered, the diagonal distance between lamps is given. Two hundred and one arc lamps were originally installed for indoor lighting, and these are all fitted with concentric diffusers. Thirty arc lamps are used for outdoor lighting. Of the total number of arc lamps now in use the majority are of the multiple type. Series arc lamps, supplied from constant-current transformers, are used for all-night lighting of the buildings and grounds. It is believed that this distribution of arc and incandescent lamps makes the Keyser Valley plant one of the best lighted railroad repair shops in the country.

REINFORCED CONCRETE POLES FOR TRANSMISSION LINES.

Experiments are being made on some of the Canadian transmission systems with reinforced concretes poles. The cedar poles heretofore used are becoming scarce, inferior in quality and high in price. In addition cedar poles require to be set closely together where heavy wires are carried, and this means large numbers of cross-arms and insulators. Steel poles have been used in some places to carry spans 400 feet long; but these are expensive and require some care in their maintenance. Wide base steel towers have also been erected where the right of way is large enough to admit of their use. On the Welland Canal transmission line, poles of reinforced concrete are used at railway and road crossings where extra high poles are required.

The poles are manufactured on the ground as it has been found very expensive to transport them on account of their great weight; a 35-foot pole for ordinary line work weighing about two and one-half tons, and a 50-foot one about five tons.

Most of the poles so far made have been calculated to stand a horizontal pull at the top of 2,000 pounds, and tests that have been made show that the calculations have been correct, all standing the full load without any impairment, except one, which failed at 2,025 pounds, the cause being a flaw in the weld on one of the steel rods.

All poles have been made square, with the corners champered off, on account of ease in making and also on account of the saving in steel over any other section. The poles are molded in wooden forms, in a horizontal position, the top side being left open and finished with a trowel. Foot steps are imbedded in the soft concrete as the pole is being made and bolts for cross-arms also, or holes are left so that a bolt may afterwards be put right through the pole. The concrete is composed of 1 part best Portland cement, 2 parts clean sharp sand and 4 parts of finely broken stone; although gravel has been used with success. The poles are quite elastic. They do not require painting, being of a pleasing gray color, and it is claimed are not affected by the weather. Two 150-foot cement poles will shortly be erected at St. Catherine's to carry wires over the old Welland Canal for the Lincoln Electric Light & Power Company.

The cost of the concrete poles depends on local conditions and the specifications regarding material and strength. It is stated that, as a general rule, the cost is 25 per cent. less than that of a steel pole of similar strength. They present a better appearance than these latter, and do not rust at the ground line.

WINDOW LIGHTING.

BY E. R. ROBERTS.

To the central station manager who is anxious to improve his load factor, the lighting of store windows would seem to be a very attractive field. The central station manager has for some time appreciated the benefit which accrues to him as well as to the customer through the sale of electric current for advertising in the form of electric signs; yet the field of window lighting, which should prove fully as lucrative, lies in a state of more or less neglect.

One cannot travel about the country, especially the smaller towns, without realizing more and more that such is the case, and that the art of window illumination as practised by many so-called enterprising merchants falls far short of what good practice demands.

Reviewing the situation one comes to the conclusion that the cause of this state of affairs is a lack of co-operation between the merchant and the light man, with the result that the window installation is off duty during the period when both parties need it the most.

During the rush of business hours people have no time to stop and view window displays. That pastime is reserved for the evening stroll after dinner, when business worries have been put aside for the day, and people are actually on the lookout for something to claim their interest. Needless to say, a dismal, poorly lighted business street at night repels about as many pleasure seekers and strollers in search of recreation as a brightly lighted thoroughfare attracts.

The advertising value of well illuminated store windows during the evening hours after business has ceased, is not a theory, but a substantiated fact, which any up-to-date merchant will appreciate and be eager to take advantage of just as soon as the electric lighting company meets him half way with a reasonable proposition. The merchant has the incentive, but awaits the inducement. Meanwhile, he continues to throw off his window switch at closing time.

The central station manager no doubt appreciates the value of the long-hour customer, and goes after every drug store, saloon or restaurant in sight. The owner of show windows is no less desirable as a customer, and it is to the lighting company's advantage to make a rate for window lighting during the evening hours which will be well nigh irresistible to a progressive merchant.

Window lighting service is needed continuously during a definite period of each day. It is more or less isolated and free from interference, and is much the same as electric sign service. Consequently, the flat rate system of charging is especially applicable, and has its strong advocates. In any case, whether the meter or flat rate be employed, the problem of shutting off the light at midnight, or earlier if desired, is easily solved by the use of an automatic time switch, which may be sold or rented to the customer.

In a window lighting campaign the electric light company should not only establish an attractive charging rate, but it should lend its influence toward the more intelligent use of electric light as a means to an end, thereby bringing to the attention of its prospective customers the advantages of electric service, while at the same time winning the confidence and respect of its patrons.

As in all other forms of lighting, except sign work, in the installation of window lamps it is too often forgotten that illumination, and not mere light, is the object sought. Many a fine window display is greatly weakened by the harsh, spectacular, and even blinding effect of unshielded border lamps, and possibly one-third the amount of energy delivered to the concealed reflector lamps would greatly enhance the value of the illumination.

Another point which demands careful consideration in window illumination is the color or quality of the light provided. It is a well known fact that colored goods and wares are only seen in their natural hues when viewed by natural light, and that the various tints are materially altered by the use of artificial light of different qualities, a notable example of this being the effect on colors produced by the mercury vapor lamp. Since the window space of a store is set apart solely for the purpose of attracting buyers it is evident that a light of suitable quality is of even greater importance here, than it is in the store itself.

The incandescent lamp by virtue of its neat, compact structure in comparison with the bulky arc lamp, and its numerous advantages over the Welsbach gas lamp, has grown very popular in the field of window lighting; yet, in the orange color of the incandescent light there is still much to be desired. The efficient Nernst lamp with its softer and whiter light is particularly applicable in this field where alternating-current is available.

THE POWER STATION.

BY FRED N. BUSHNELL.

Since the advent of the direct-connected generator, the tendency in power-station design has been toward a more systematic and compact organization of the generating apparatus and the utmost simplicity of the entire plant consistent with the highest efficiency. The practice of different engineers has gradually worked toward a type of station which is now so generally adopted for street railway work where limitations are not placed upon the design by the size or shape of the available site, that it can fairly be said to represent standard practice in modern power station engineering. It embodies the following essential principles:

1. Simplicity of design.
2. Sub-division of the plant into separate sections, so as to localize the effect of trouble to any part of the generating apparatus.
3. Provision for the symmetrical extension of the plant to provide for future power requirements.

This station in its simplest form consists of a boiler room, engine and generator room, and switchboard gallery, arranged in parallel lines and separated from each other by substantial fireproof walls. In stations of very large size the boilers are frequently arranged in two tiers, or in groups, each group having its own chimney and flues and independent systems of feed and steam piping. This arrangement of the station is now generally referred to as the unit system, the distinguishing feature of which is that the boilers, engines and generating apparatus are arranged in separate units or groups, each one of which embodies all of the essential features of a complete generating plant, and the great advantage of which lies in the fact that trouble with any single piece of apparatus is localized, so that its effect is felt only in that unit of which it forms a part. Provision for carrying the load in the event of a breakdown of any important part of the apparatus is made by installing an additional or spare unit.

While the unit system is now almost universally employed in the larger power stations, it is usually somewhat modified for smaller plants where the liability to interruption of the service is not so great or the results so disastrous, the chief difference being in the arrangement of the steam and

feed piping. The steam piping from the boilers is run to a longitudinal header, from which the connections to the engines are taken off at convenient points. This steam header is divided into sections by means of gate valves, which permit of any section being cut out at the convenience of the operator for the purpose of making repairs. Usually two systems of feed piping are provided, one of which supplies hot water to the boilers through the heaters and economizers, while the second, or auxiliary system, supplies cold water, or water direct from the heaters, in case of trouble with the main system. This arrangement of piping provides sufficiently against interruption in small and medium-sized plants, and in a system carefuly laid out with due consideration for the troubles which are likely to arise, it is hardly probable that the disarrangement of any one part will cause serious interruption of the service.

At the present time alternating-current generating stations and distributing systems are regarded as the most efficient to install in large cities where heavy traffic is distributed over a very large area, requiring current to be delivered to the line at a number of points, and where the interest upon the investment in direct-current feeders and cost of their maintenance would amount to more than the same charges plus the conversion losses in an alternating-current system; and for long suburban or interurban railways where the power required at any one point is small as compared with the total power generated. The use of alternating-current apparatus has steadily increased since its introduction, until at the present time approximately 60 per cent. of the total power used by electric railways in the United States is generated by this type of apparatus.

In cities where the bulk of the business is within the economical radius of distribution for direct-current lines, and where direct-current generators form the larger part of the present equipment, the common solution of the problem is to use this type of apparatus for city work, adding alternating-current apparatus to supply the more distant portions of the system, or roads operating through outlying districts.

There is undoubtedly a great advantage in having all the apparatus of a uniform type. This simplifies the wiring and switching part of the electrical equipment, and permits of a more efficient distribution of the load in the station. But there can be no conversion of energy without loss, and in cases where a considerable part of the system can be supplied with direct current without the use of rotary converters, the composite type of station will frequently be found to offer advantages in lower first cost and higher efficiency.

The location of the power station, its general character, and the type of apparatus to be installed, depend to such an extent upon local conditions, that it is difficult to offer suggestions covering these points except in a general way.

If possible, the station should be located near an ample supply of water for condensing purposes, in order to secure the advantages from the use of the most efficient types of steam apparatus, and if possible, convenient also to a steam railroad or tide water, where the coal can be received and handled for the least expenditure of labor. Its location in reference to the distributing system will depend upon the extent and type of the system employed. If the direct-current system is used, it will be desirable to select a location as near as possible to its center of gravity, in order to reduce the investment in copper, but in the case of an alternating-current distributing system, this is of less importance, and greater consideration will be given to the cost of the available site, the nature of the soil, cost of foundations, etc.

The building should in all cases be of fireproof construction and of neat and attractive design, appropriate to and suggestive of the purpose for which it is used. In determining upon the dimensions of the building, it is important that ample room be provided for all of the apparatus to be installed, so as to avoid unnecessary crowding. Passageways should be provided between each battery of boilers, and at the rear for the convenience of attendants in cleaning the tubes and connections and for making necessary repairs. Sufficient room should also be provided around each piece of apparatus in the engine room, so as to enable the attendants to inspect it regularly and keep it thoroughly clean, and to provide for the removal of any part in case of repairs.

In large cities, where land is extremely valuable, or the available area limited, the amount of power which can be generated per unit of ground area occupied is frequently the controlling factor in deciding upon the power station plans, and in such cases it is not always practicable to provide all of the space usually regarded as desirable for the convenience of attendants. This condition rarely exists, however, except in the larger cities, and in a great majority of cases no excuse can be offered for crowding the machinery to such an extent that it cannot be kept in proper condition and conveniently repaired by those responsible for the management of the plant.

Cleanliness is absolutely essential to the successful operation of an electric railway power station. It is necessary that the building itself be kept free from oil and dirt, and each piece of apparatus thoroughly clean at all times, in order to maintain it in its highest state of efficiency. The designing engineer should contribute his share towards this result by providing ample light throughout the building—boiler room as well as engine or generator room. All the walls of the building should be painted in some light shade, preferably with some kind of enamel paint which can be easily washed down and kept clean. This will be found to reflect the light into dark corners of the building or spaces around the machinery, which might otherwise form receptacles for dirt and rubbish. It will add very much to the cleanliness and general appearance of the plant, and will contribute toward its successful running.

In designing a power station, the primary object in view is to deliver power at the bus-bars for the least expenditure of money, due importance, of course, being given to reliability of operation, which is the controlling principle in power station work. The fixed charges—interest, depreciation, insurance and taxes, should be as carefully considered as the cost of fuel, labor, supplies, repairs and other items which make up the operating expenses. Consideration should be given to each of these elements in proportion to its importance as a factor in the cost of power. In the great majority of cases fuel is the most important item of expense, frequently amounting to more than all other operating costs combined, and the perfection of these details of design and management which will effect the greatest economy in its use will usually make the best return for the time and labor expended.

Electrical apparatus has now been developed to such a state of perfection that in a well-designed and carefully managed power station over 90 per cent. of the power of the engines is converted into electrical energy and delivered to the transmission system for the operation of cars.. It appears, therefore, that no very great gain in coal economy is to be expected from the further improvement of electric generators or switching apparatus, and engineers are directing their efforts more than ever before to the steam portion of the power station, which offers a more promising field for a reduction in the cost of power.

The number and size of units to be installed is one of the most important problems bearing upon fuel economy which the engineer is called upon to solve. In order to obtain the maximum efficiency from the prime movers and their auxiliaries, it is necessary that they should be proportioned to the load they are intended to drive, so that if possible they may be operated at all times at or near their rated capacity.

In electric railway power stations it is not regarded as practicable to change the speed of the air or circulating pumps, or to alter the quantity of cooling water, to suit the varying loads upon the station, and these auxiliaries are usually operated at a point sufficient to take care of the maximum load. The power required to drive them is therefore practically constant, and their steam consumption per unit of output will vary indirectly as the load on the main engines. Under ordinary operating conditions, where the exhaust steam is used for heating the feed water, only about 12 per cent. of the heat in the total steam generated can be used for this purpose, and all steam used by the auxiliaries in excess of this must go to waste; and it follows that in addition to the losses due to the reduced efficiency of the prime movers at light loads, the percentage of loss in the auxiliaries will increase very rapidly as the load upon the main engine decreases, and the best economy of the entire plant will be obtained only when the engines are operated at or slightly above their rated capacity.

The writer has before him the operating statistics of two railway power stations, a comparison of which illustrates the importance of proper attention to this subject. For convenience they will be referred to as Station A and Station B. Both stations

furnish power for suburban railways upon which sufficient cars are run to provide a fairly uniform load during the greater part of the day, although subject to more or less violent temporary fluctuations. The general designs of these stations and their equipments are such that the fuel used per kilowatt-hour should be practically the same, provided the engines could be kept well loaded in both cases. In Station A there are three units, and the load conditions are such that one unit is operated during the night and early morning, when the travel is light; two are operated during the greater part of the day, and three at the peak of the load, which occurs shortly after 6 o'clock in the evening. By careful atention to the changes in the load it is always possible to keep the running engines fairly well loaded.

In the case of Station B there are two units. The load at night and early morning is very light, so that the engine used is only about half loaded for this period, whereas for the greater part of the day the load is a little more than one engine should be required to carry, and it is therefore necessary to run both engines. The result, of course, is that the average load on the station is only a little more than 50 per cent. of the rated capacity of the running engines, and they are, consequently, extremely wasteful of steam; and, too, the exhaust from the auxiliaries is probably quite a little in excess of that required to heat the feed water, which will also account, in a measure, for the low efficiency of the plant. Five pounds of coal per kilowatt-hour is the record of this plant, as compared with 3.8 lbs. for Station A. The greater part of this discrepancy is undoubtedly due to the more efficient load conditions in the latter station. It is probable that had a storage battery been added to the equipment of Station B, the load on the engines could have been regulated so as to have made a much better showing in coal consumption, but it is still problematical if there is any net gain from the use of storage batteries in railway work, and the writer is disposed to think that the use of three smaller engines in place of two large ones would have been the proper solution of the question. Undoubtedly a saving in coal of from 15 per cent to 20 per cent would have resulted from the use of engines better proportioned to the load.

In deciding upon the number and size of units, therefore, it is necessary that a careful study should be made of the load conditions throughout the entire day. In providing an increase of power for existing roads, data will be available from which station load curves under varying conditions of traffic can be constructed, and a fair average decided upon as the basis for determining the size of the units. In the case of a new railroad proposition, this information will be more difficult to obtain, and an approximate load curve will have to be constructed from a study of all of the conditions bearing upon the subject. This involves decisions upon such matters as the location of track, with special reference to grades and curves, the distribution of copper in the feeder system, the weight and equipment of cars and train schedules, all of which are important factors in determining upon the power required.

It is often necessary to estimate the size of a new power station before the final survey of the road is completed, or the details of the feeder system or train schedules definitely decided upon. In such cases the engineer will have to apply such data as he is able to obtain from other roads in which the conditions of track and the operating conditions are similar. But such data should always be used with the utmost caution, as vital differences in grades, in the feeder system, or in train schedules, must necessarily exist, which will render it extremely difficult to make comparisons sufficiently accurate for a final decision upon the size of the station.

Having ascertained the power required during the different hours of the day, the plant should be divided into as few units as will enable the engines and generators to be operated at or near their rated capacity, while at the same time a sufficient number should be installed so that in the event of trouble one can be shut down without causing interruption of service. A 3-unit station will permit of a fairly uniform distribution of the load in small plants, and in case of accident to one unit, the other two should be able by overloading, to supply sufficient power until repairs are completed. This number of units is therefore regarded as the minimum which should be installed in any power station.

The type of apparatus to be used, whether alternating or direct-current, will not materially affect the design of the station except in so far as the question of the use of reciprocating engines or steam turbines is involved. Up to this time the steam turbine, which is rapidly growing in favor for electric railway work, has been designed almost exclusively for use in connection with alternating-current generators, and the manufacturers of electrical apparatus have held out scant encouragement that its speed could ever be so modified as to make its use with direct-current generators, particularly the larger sizes, practicable. Reciprocating engines have, therefore, been regarded as the only type of steam motor available for this class of work. It is probable that this will be the case for some time to come, but it is interesting to note that considerable progress is being made in the development of direct-current turbo-generators. A number of machines of this type as large as 500 kw. capacity are in operation, and work is well advanced upon units as large as 2,000 kw. There seems to be a good ground for the belief that this problem will be successfully solved, and that in the near future this type of apparatus will be available in sizes as large as are generally required for direct-current work.

Engineers and steam users generally have been prepared for some time to welcome any form of prime-mover which could be shown to possess any considerable advantage over the reciprocating engine, as the latter had come to be regarded as having largely fulfilled its possibilities, and no very great improvement in economy was to be looked for. The steam turbine seemed to offer the solution of the question, and while, at the time of its introduction into this country, its superior economy had not been demonstrated, its great simplicity as compared with reciprocating engines, lower first cost, and less floor space occupied, insured its prompt adoption by a large number of power users, and from the first its progress has been rapid. In a report of the committee for the investigation of the steam turbine made to the National Electric Light Association last June, it was stated that there were in operation at that time 224 turbines of an aggregate capacity of over 250,000 horse-power, the greater number of which had been installed in the last two years. The writer is informed that the orders for turbines taken by the largest two manufacturers in this country aggregate (July 1, 1905), over 800,000 horse-power.

The remarkable progress made in the manufacture of these machines, and their general adoption by many of the most progressive railways in the country, proves them to be a most formidable competitor of the reciprocating engine, if, indeed, it does not indicate that they have already established their commercial superiority.

It is to be regretted that most of the data upon the efficiency of steam turbines have been derived from tests covering very short periods of time, usually only a few hours, and that so little data is available of their performance under actual service conditions. To the street railway manager or engineer, power station records for long periods, showing the coal consumed per kilowatt-hour, or, better still, the efficiency of the plant expressed in percentage of heat energy in the coal converted into electrical energy at the switchboard, are of much greater interest and value than the record of any number of short-time tests for steam consumption only, as it provides him with a much more practical means of making comparisons with the performance of other stations with which he is familiar. The data which have been published illustrating the relative economy in steam consumption of turbines and reciprocating engines rarely ever shows comparisons between units operating under identical conditions as to steam pressure, superheat, or vacuum and therefore does not fairly represent the relative performance of the two types, and, too, the steam consumption of the auxiliaries is also invariably omitted, so that it is impossible to form an intelligent opinion as to the additional cost of the higher vacuum required for the turbine.

Up to this time most of the turbines installed in electric railway power stations are operated in connection with reciprocating engines, and owing to the difficulty of separating the operating charges, it has been practically impossible to obtain reliable information as to their performance under commercial conditions.

One of the plants where turbines are exclusively used is the Quincy power station of the Old Colony Street Railway Company, and through the courtesy of P. F. Sullivan, president of this company, the writer is permitted to publish some in-

formation regarding the performance of this station. This information was kindly furnished by C. F. Bancroft, superintendent of motive power and machinery.

It should be stated at the outset that this station, which will eventually furnish power for that portion of the Old Colony Street Railway Company's system, extending from Quincy on the north to the city of Fall River on the south, is not yet in full operation. Its connection with the latter city, where a large part of the current is to be used, has not yet been made, so that at present it furnishes power for only about one-third of the number of cars which it will eventually drive. Only two of the five turbines in the station are required for this work. One of these machines is run for 17 hours per day, and two for 24 hours per day. When the station is in full operation there should be a more uniform load, and it is expected that the station efficiency will be considerably increased.

The station contains five 2,000-kw., 4-stage vertical turbines, running at 750 r.p.m., and connected to 13,200-volt, 25-cycle alternating-current generators. The steam pressure is 200 lbs. There are ten horizontal water-tube boilers of 750 horse-power each, equipped with internal superheaters, giving to the steam an average of 65° superheat. Under-feed stokers are used. There are no economizers. One turbine is supplied with steam driven auxiliaries; the other four have motor driven auxiliaries. At present, while only two units are in operation, the feed water is heated to 200° F. by the exhaust from the steam auxiliaries. The average daily output is 52,500 kw.-hours, giving a load factor of 54.7 per cent for the two machines. Georges Creek Cumberland coal is used, having an average calorific value of 14,000 B.T.U. per pound. The average coal consumption for this station, operating under the conditions outlined above, is 2.94 lbs. per kilowatt-hour, showing an efficiency of 8.36 per cent. This record covers a period of six months, ending June 30, 1905.

While this performance does not furnish conclusive evidence of the superiority of the turbine over reciprocating engines in electric railway work, it compares favorably with the results obtained in a large number of the better class of stations using the latter type of prime movers, and gives some force to the opinion that in actual practice there will be found to be very little difference in the coal consumption of steam turbine and reciprocating engine plants operating under similar conditions.

In order to develop the highest efficiency of the steam turbine, it is necessary to operate with a very high vacuum. It is claimed that each inch of vacuum above 26 ins. will increase the economy from 3 per cent to 4 per cent, and condensing apparatus is usually recommended which will produce a vacuum of about 28 ins. of mercury, or 2 ins. to 2½ ins. higher than that regarded as the most efficient for reciprocating engines. The type of apparatus generally installed consists of a surface condenser with a centrifugal circulating pump, dry vacuum pump and hot-well pump. In practice no trouble has been experienced in obtaining the high vacuum desired with this type of apparatus, but whether the gain of 3 per cent or 4 per cent in coal is sufficient to warrant the additional first cost and cost of operating this rather complicated system, is a question which would seem to be open to discussion. In cases where the cost of feed water is a material factor in the cost of power, or where it contains a large percentage of calcium or magnesium carbonate, or other scale-forming materials, there will be great advantage in using a surface condenser on account of the pure distilled water returned to the boilers, but where these conditions do not exist, it will frequently be found to be practicable to use some simpler form of condensing apparatus, such for example as the injector or barometric type of jet condensers. These types of condensers offer very great advantages over the surface condenser in the matter of lower first cost, space occupied, greater simplicity and less cost of maintenance. Up to this time they have not been very generally used, but there seems to be no good reason why they should not work as satisfactorily in connection with steam turbines as with reciprocating engines, and when properly proportioned to the work and installed with tight piping throughout, it is believed that in many cases they will prove to be as satisfactory as the more complicated types.

A considerable economy in the steam consumption of both reciprocating engines and steam turbines has been shown to result from the use of superheated steam. In plants equipped with either of these types of prime movers using dry saturated steam, the introduction of superheated steam can generally be depended upon to effect a saving in steam of about 1 per cent. for every 8 degrees or 10 degrees of superheat. Where the quality of the steam is not so good, and the conditions are such that the condensation in the pipes or cylinders of the engines is excessive, the saving may be much greater than this, sometimes amounting to 1 per cent for every 4 degrees or 5 degrees of superheat.

With reciprocating engines, condensation in the cylinder resulting from the great difference in temperature between the incoming steam and the surfaces of the cylinder which have just been exposed to the temperature of the exhaust steam, has been recognized as one of the greatest sources of loss. Various means have been employed to reduce this loss, such, for example, as the use of steam jackets and reheaters, but these devices add materially to the complication of the engine, and under the most favorable conditions only effect a partial saving. For these reasons they have not been generally adopted in power station work. Superheated steam has been found to be a much simpler and more effective method of accomplishing this result.

Our knowledge of the subject of steam turbines is still so limited that it is impossible to state with any degree of positiveness just where the various losses occur, or to what causes we must attribute the gain in efficiency from the use of superheated steam. Undoubtedly a portion is due to thermodynamic reasons, and it has been suggested that a large portion is also due to the diminution of fluid friction within the turbine. Owing to the very high steam velocities in this type of apparatus, the friction of the steam passing over the surfaces of the buckets must cause a considerable loss, and this probably very much greater where the steam carries a large percentage of moisture than when it is dry or superheated. It is probable, therefore, that the larger part of the gain due to superheating can be attributed to this cause.

The prevention of the deposit of water on the inside of the turbine casing, also, must effect some saving, although this gain is probably small as compared with that resulting from the diminution in the friction of the steam as it passes over the surfaces of the buckets.

Whatever the causes may be, there can be no doubt that there is a very marked gain in efficiency in steam turbines from using superheated steam, amounting to about as much per degree of superheat as in the better class of reciprocating engines.

The following table, compiled by R. M. Neilson, shows the reduction in steam consumption in steam turbines and reciprocating engines due to superheating. These statistics were obtained from a number of tests made in this country and in Europe. The apparent discrepancy in these tests is explained by the statement that there was considerable difference in the quality of the steam in the different cases, and the engines were of different types and of different sizes:

Steam Turbines			Reciprocating Engines		
Degrees Fahr. of Superheat	Percentage Reduction of Steam Consumption	Percentage Reduction per Degree Fahr.	Degrees Fahr. of Superheat	Percentage Reduction of Steam Consumption	Percentage Reduction per Degree Fahr.
13	6.1	0.47	31	7.86	0.25
50	8.0	0.16	40	8.65	0.22
60	5.4	0.09	50	12.00	0.24
66	12.1	0.18	100	20.55	0.20

Unfortunately, superheated steam is now known to be rather expensive to produce, particularly at the higher temperatures, and consequently economy in steam consumption does not necessarily mean economy in the consumption of coal. The chief advantage in its use is obviously in the saving which can be made at the coal pile, and unless this saving can be shown to be sufficient to pay for installing and operating the necessary superheating devices, it will be extremely difficult to convince a careful street railway manager that it will be profitable to use it.

This is a subject upon which there is a vast amount of conflicting information. In a number of instances the use of super-

heaters has been discontinued either on account of mechanical difficulties or because there was not a sufficient saving in coal to pay for keeping them in service. In other cases no mechanical difficulties have been experienced, and the saving in coal has been all that could be reasonably expected.

It is noteworthy that manufacturers of reciprocating engines and steam turbines, as well as engineers, while still recognizing the value of superheated steam, are disposed to be much more conservative than formerly in recommending its use. At this time, the weight of opinion seems to be in favor of a moderate amount of superheat, say not exceeding 125 degs. Within this limit there should be a sufficient saving at at the coal pile to justify its use, while the temperature is not sufficiently high to cause serious mechanical difficulties with any of the various types of steam apparatus generally used.

For many years after the inauguration of the electric railway industry, power station engineers seemed disposed to devote the greater part of their energies to perfecting the arrangement of engines, generators and switching apparatus, frequently neglecting the more important, though less showy, boilers and their accessories. In recent years they have come to realize that a larger percentage of saving can be made by a proper attention to the design and management of the boiler room than in any other department, as it is here that the greater number of preventable losses in a power station occur.

The designs of the standard types of steam boilers which are now generally used have been perfected to such a degree that efficiencies as high as 70 to 75 and even 80 per cent. have been attained under favorable conditions, and there are very few improvements which the power station engineer can suggest which will produce any considerable saving in fuel.

The design of the furnace, as distinguished from the boiler, on the contrary, is one requiring careful thought and study, to make it conform to the conditions required for the perfect combustion of the specific kind of fuel which is to be used. Anthracite coal, owing to its small percentage of volatile matter, can be satisfactorily burned in almost any kind of furnace, provided the grate area and the draft are sufficient to burn the quantity required to develop the desired capacity, but in the case of semi-bituminous and bituminous coals and lignites, containing a much larger percentage of volatile matter, the furnace should be so designed that this volatile matter, as well as the fixed carbon, will be completely burned in order to develop the full heating value of the fuel.

The following conditions are necessary to insure the complete combustion of the fuel:

1. A sufficient supply of air.
2. Thorough mixture of air and fuel.
3. A sufficiently high temperature of the air and the combustible gases to insure their ignition and perfect combustion before they come in contact with the cooling surfaces of the boiler.

The principal source of loss is due to imperfect combustion of the volatile gases, which are distilled very rapidly after fresh coal placed upon the fire, and not being mixed with air at a temperature sufficient to cause ignition, pass off unconsumed; or the air supply and the temperature being sufficient, they are allowed to come in contact with the comparatively cool surfaces of the boiler, and their temperature reduced below the ignition point before combustion is completed, so that they escape when only partially burned. The mixture, temperature and time are, therefore, important factors in the combustion of the volatile gases, and it follows that the combustion chamber should be of sufficient size to allow the gases to become thoroughly mixed, and that they should be raised to a sufficiently high temperature, and be protected by fire-brick walls and arches from the cooler surfaces of the boiler shell or tubes until the combustible portion has been entirely consumed.

As to the proper place to admit the air for the combustion of the volatile gases, D. K. Clarke says:

"It is a matter of perfect indifference as to effect in what part of the furnace or flue it is introduced, provided this all-important condition be attended to, namely, that the mechanical mixture of the air and gas be continuously perfected before the temperature of the carbon of the gas, then in a state of flame, be reduced below that of ignition."

A number of furnaces have been devised in which the air has been admitted at the bridge wall or at the sides or front of the furnace above the grate, and there have been many ingenious plans for heating this air to the proper temperature before its admission to the combustion chamber. Some of these furnaces have been fairly successful as a means of reducing the smoke, but it is doubtful if the admission of air above the grate has ever materially increased the efficiency of the furnace. By far the most common practice is to admit all the air through the grate, that required for the combustion of the volatile gases being heated to the proper temperature by passing it through the bed of incandescent fuel.

In many of the larger railway power stations the flue gases are regularly analyzed to ascertain the amount and distribution of the losses due to incomplete combustion and the amount of excess air admitted to the furnace, which information is necessary to enable those in charge to operate the boilers in the most efficient manner. The only way in which the waste which takes place in the furnace can be detected is by such an analysis, and its importance as a means of reducing boiler room losses is so great that it merits a much more general use.

In the combustion of coal the object in view is to produce the highest possible percentage of carbon dioxide per unit of fuel burned. The higher the percentage of carbon dioxide, the more perfect will be the combustion of the fuel and the higher the furnace temperature, as is shown from the fact that a pound of carbon burned to carbon dioxide will produce 14,000 B.T.U., while only 4450 B.T.U. will be produced when, on account of an insufficient supply of air, carbon monoxide is formed. The gas analysis will show the percentage of carbon dioxide, carbon monoxide and oxygen. This information will enable the chemist to determine the total heat in the escaping gases, the amount of unconsumed gas, and the losses due to an excess air supply, and will also indicate the cause of these losses and suggest the proper remedy.

A low temperature of escaping gases is frequently regarded as an indication of efficient furnace conditions, but it is quite as likely to be caused by an excess of cold air, due to too strong a draft, uneven fires, or leakages through the boiler settings. The true condition of affairs can only be revealed by means of an analysis of the flue gases. Anything which will increase our knowledge of the conditions which take place within the boiler setting, and will permit a more intelligent use of fuel, should be encouraged, and for that reason the practice of analyzing the flue gases is recommended in all railway power stations where the cost of fuel is an important factor in the cost of power. It is always preferable to have this analysis made by an experienced chemist, but in small stations where the saving to be made is not sufficient to warrant the employment of such a man, it is said to be possible to obtain fairly satisfactory results from the use of one of a number of automatic or semi-automatic devices which are now manufactured for the purpose.

Mechanical stokers are now almost universally employed in electric railway power stations, on account of the increased efficiency over hand-fired furnaces and the reduced cost of operation. In a properly constructed furnace of moderate size, equipped with flat grates, an intelligent and careful fireman will produce results equally as satisfactory as any which have been obtained with any of the various types of mechanical stokers; but the trouble is that such firemen are not plentiful, and it is extremely difficult to secure men who will produce uniformly good results for long periods of time. For this reason the average fuel economy in a railway power station will generally be found to be somewhat better where the firemen are assisted by some form of mechanical stoking device.

It should be borne in mind, also, that in order to economize in space and the initial cost of the plant, the size of the boilers and the rate of combustion has steadily increased in the last few years until they have now reached a point where it is doubtful if the larger sizes can be properly stoked by hand, even by the most competent firemen.

The use of mechanical stokers is necessary in connection with these large sizes of boilers, in order to drive them up to the capacity required in electric railway plants.

There can be no doubt that mechanical stokers accomplish a considerable saving in boiler house labor. A reasonable day's work for a fireman is the shoveling of suffi-

cient coal for about 500 horse-power of boilers, which in a railway power station will amount to from six to eight tons every twelve hours. Where automatic stokers are used, and coal is delivered to the hoppers by gravity, one man should be able to take care of about 2,000 horse-power of boilers, which is equivalent to a reduction in labor of 75 per cent. The cost of maintenance of automatic stokers is somewhat greater than that of flat grates, and additional labor is required for repairs as well as for tending the coal handling machinery usually installed in connection with them, so that the net saving in labor will be somewhat less than that indicated above. There is a point, of course, at which this saving is not sufficient to pay for the additional fixed charges and repairs upon the mechanical stoking devices. This point is reached in a boiler plant of about 2,000 horse-power capacity. In a plant of greater capacity than this, automatic stokers can generally be shown to return a sufficient net saving to warrant their use, while in smaller plants it will frequently be found to be profitable to use them on account of the cheaper grades of fuel which can be burned and the greater capacity which can be gotten out of the boilers.

Perhaps the most difficult problem to be solved in connection with the power station is to secure proper attention to details of operation by the subordinate employees. In the most carefully designed plant, equipped with the most efficient types of machinery, the results which the railway manager and designing engineer may reasonably expect in the way of economy will not be achieved unless the utmost care and vigilance are exercised by the operating forces. The successful operation of the station will depend largely upon the way in which the forces are organized, and discipline maintained. Just how the station organization should be made up is a question which can only be decided for each plant after a careful study of all the conditions; but it is safe to say that however the various departments may be organized, there should be one man in supreme authority, possessing considerable executive ability as well as a thorough practical knowledge of steam and electricity, whose decision should prevail in the event of disagreement among the heads of departments or at times of emergency. As he is the one who will be held responsible for the successful performance of the station, it is essential that whatever regulations there may be regarding the employment of his subordinates, he should have full authority to dismiss any who prove to be incapable or are not disposed to be attentive to their duties. It will be practically impossible to maintain proper discipline if among the employees there are those who feel a certain sense of security in their position through the influence of some one higher in authority than the man in charge of the station.

The work of the greater number of station employees is necessarily of a routine character. It is nevertheless important that they should be thoroughly instructed in their duties and required to perform them with the utmost regularity. For example, an oiler employed upon an engine should receive instructions as to the minutest detail of the work that he is required to do. He should not only be required to see that his lubricators are full and working properly, and that every part is receiving a sufficient quantity of oil or grease, but he should feel of every bearing, and should observe every part of the engine as he passes around it to assure himself that it is in proper operative condition. He should be required to perform these duties at regular intervals of every 20 or 30 minutes, and his attention should be called to the time for him to commence his rounds by a bell or whistle, or some other form of signal. If there is any part requiring attention, it should be immediately reported to the engineer in charge, who will thus be given an opportunity to apply the proper remedy before the trouble has developed to such an extent as to cause damage or interruption to the service. If the oiler attends to his duties properly, there will be no trouble from hot bearings, from keys, pins or bolts working loose, or from any change in the adjustment of any part which it is possible to discover when the engine is running.

The work of all other station employees should be systematized along the same lines. The watch engineers should report in writing to the engineer in charge details of the apparatus which in their judgment require attention, and as soon as the machinery can be shut down these parts should be carefully inspected, and if they show signs of weakness or excessive wear, immediately renewed or repaired. An examination of the enclosed parts of the engines and other working machinery should also be made at frequent intervals and before there are any outside evidences of trouble.

It is necessary that all subordinate employees should be under constant supervision to insure a proper attention to their duties, but this is especially true of the fire room forces. Firemen are not generally disposed to take as much interest in their work as employees in other departments. They seem to be content to remain as firemen, and rarely endeavor, by excelling in their work, to advance their positions. It is in this department that the greatest losses will occur through indifference on the part of the attendants, and it is therefore of the utmost importance that their work should be carefully done. The only way to accomplish this known to the writer is to place this department in the immediate charge of an intelligent and capable man, whose salary and the knowledge that the permanency of his position will depend upon the results produced, will be sufficient for him to keep constantly in touch with those immediately under him and insist upon their performing their duties properly.

In most power stations records are kept of the coal and water consumption, the temperatures of the feed-water and flue gases, and the station output, by which the performances of the station from month to month can be compared. These records furnish a check upon the condition of the station, the manner in which it is operated, and assure its being maintained in a high state of efficiency. The writer has found that in addition to these records an occasional test of the entire plant under actual operating conditions for periods of, say, 24 to 48 hours, are also of great value as a means of furnishing definite knowledge as to just what the station is capable of doing. Such tests also have a certain educational influence upon the employees, particularly the firemen, as they illustrate to them what can be done when all engaged on the work are exerting their best efforts to secure the most efficient results possible.

At the Rhode Island Suburban Railway Company's Manchester Street station all of the usual records are kept, and the quantities and costs carefully determined for each month, and tests of the entire plant are also made as suggested above. The writer believes that these tests have a sufficient influence upon the regular performance of the station to justify a brief description of it, and the publication of the results in the matter of coal consumption from the time it was placed in commission, showing the gradual improvement in efficiency.

This station was originally designed for the Rhode Island Suburban Railway Company to furnish power for its lines operating in the vicinity of Providence. It was intended to use horizontal units, and two 1,500-kw. alternating-current units and one 1,600-kw. direct-current unit were purchased. Before work on the building had progressed beyond the foundations, however, it was decided to increase the capacity of the station by installing two additional direct-current units of 2,500-kw. each. This required a number of changes in the structure, and necessitated double-decking the boiler room in order to provide the necessary additional boiler capacity. The present equipment of the station consists of fourteen horizontal water-tube boilers of 520 horse power each, eight on the lower floor and six on the upper floor. The boilers on the lower floor have no superheaters, but those on the upper floor are equipped with internal superheaters, each made up of eighty-four 2-in. tubes, suspended below the boiler drums. The superheaters on two of the boilers were designed for only 125 degrees of superheat, and contain 615.3 square feet of effective heating surface each. Those on the other four boilers were designed for 150 degrees of superheat, and contain 855.5 square feet of heating surface. Each boiler has 5,159 square feet of heating surface.

Roney mechanical stokers are used, each containing 112 square feet of effective grate surface. A 280-tube Green fuel economizer is installed directly back of each battery of boilers, the flue being so arranged that the hot gases may be passed through the economizers or directly to the main flue as desired. The heating surface per square foot of grate is for boilers 46 square feet, for economizers 15 square feet, or a total of 61 square feet. Natural draft is used. The boiler pressure is 145 pounds. There are

three horizontal compound engines with cylinders 32 inches and 64 x 54 inches, operating at 94 r.p.m., and two vertical compound engines with cylinders 42 inches and 86 x 60 inches, operating at 75 r.p.m. All of the engine auxiliaries are steam driven. Jet condensers are used, the air pumps being of the twin vertical type. The average vacuum in the engine cylinders is 25½ inches of mercury. There are two alternating-current generators each of 1,500-kw. capacity, delivering current to the line at 11,000 volts, and one 1,600-kw. and two 2,500-kw. direct-current generators delivering current at 600 volts. The normal capacity of the station, therefore, is 96,000 kilowatts. Direct current is furnished for 24 hours per day, and alternating current from 5 a. m. to 1 a. m. There are no feed-water heaters between the engine cylinders and the condensers, but the exhaust steam from the auxiliaries is carried to two heaters located in the basement on the suction side of the feed-pumps. These heaters are made up of horizontal U-tubes arranged in series, the steam entering at the top and discharging at the bottom, while the water enters at the bottom and discharges at the top. Each heater contains 750 square feet of heating surface, and in practice all of the steam from the auxiliaries is condensed and is discharged at a temperature only about 35 degrees higher than the incoming cold water. The average daily output of the station is 102,500 kilowatt-hours.

The following is the performance of the station under actual service conditions from the time it was started in regular service, February, 1904. It should be borne in mind that the first battery of boilers with superheaters was installed eleven months after the station was started, and four months thereafter two additional batteries of boilers with superheaters were commissioned, and the performance of the station is therefore given for the period covered by these different conditions.

Eleven months, saturated steam, 2.87 pounds of coal per kilowatt-hour.

Four months, slightly superheated steam (no record of temperature kept), 2.73 pounds per kilowatt-hour.

Three months, superheated steam, average temperature at engine throttle 465 degrees (102 degrees superheat), 2.46 pounds of coal per kilowatt-hour.

The apparent reduction in coal consumption per kilowatt-hour with steam superheated about 100 degrees is 14.3 per cent., but all of this saving cannot be attributed to this cause. A large part of it is undoubtedly due to the increased efficiency of the fire room attendants. Probably not over 8 to 10 per cent. should be credited to the use of superheated steam.

Steel versus Cast Iron Fly-wheels.—Steel fly-wheels having a tensile strength of 60,000 pounds per square inch will stand a speed 90 per cent greater than fly-wheels made of cast iron.

ESTIMATING ON CONTRACT WORK.

BY LOUIS J. AUERBACHER.

The problem of estimating is simply one of analysis. When figuring on the cost of wiring a building according to a set of plants and specifications, the contractor should first carefully read the specifications to ascertain if they contain any unusual requirements. In reading the specifications the contractor should note if he is expected to do cutting and plastering, and also note if any scaffolding is required. These items increase the expense, and if not counted lessen the profit.

The specifications for the wiring of a building are usually divided into the following clauses:

- General Conditions.
- System of Wiring.
- Mains and Feeders.
- Panelboards.
- Circuit Wiring.
- Special Devices.

If the plans and specifications give the complete data, such as the size of feeders and the locations of panels, the contractor has only to write down the details on an analysis sheet (Form A) and add the cost of labor. Where the complete data are not given it is necessary for the contractor to lay out the wiring systems and take the data from these.

In making up an analysis sheet when estimating for wiring a building for electric lights, using a conduit system, all items coming under the head of panels, such as meter boards, service boards, panels, switches, distributing boxes, etc., are written down first. If the contractor has sufficient time a list of these should be made up and sent to two or three manufacturers for quotations. If the panels called for are standard, the last price of similar goods should be used.

The length of run of the mains in feeders is then measured and recorded, together with the quantity of wire and conduit required; the labor is also estimated. The circuits are next measured and the length of pipe and wire required written down; also fittings, such as elbows, couplings, lock nuts and bushings. By adding 10 per cent to the cost of the pipe, the fitting item is usually provided for. The number of outlet boxes, switch boxes, switches, receptacles, etc., and the labor for installing them are then added, together with a sum for sundries, such as cartage, car fares, inspection fees, etc.

An estimate should always be on the safe side. If better cost prices are obtained later these often offset unforeseen contingencies. In figuring the labor cost the contractor must be guided by past experience and data from the cost book. The cost for installing conduit is usually quoted at so much per thousand feet; molding, at so much per hundred feet; cleats, at so much per hundred pair, and so on.

When making a quotation, the contractor must take into consideration the amount of competition. If possible he should find out who his competitors are and how they have bid on similar work. A good plan is to add to the cost of the material a certain percentage of profit. This percentage may

FORM B (*White*). Actual size, 8 inches wide by 12 inches long.

be smaller than the percentage added to the labor cost, inasmuch as the material can be accurately estimated, whereas labor is always an uncertain item, and the percentage added should be larger to compensate for the risk.

In making estimates care must be taken to learn the character of the construction of the building. When estimating on work for a finished house it makes quite a difference whether the building is furred or not. If furred, the wires are easily "fished"; if not, floors must be taken up and the beams bored. The cost of labor is naturally double in buildings not furred.

In figuring on a molding job, the fact that the ceiling is of lath and plaster and therefore requires the molding to be fastened with screws, makes the cost of labor greater than if the ceiling were such that nails could be used. In close competition, these minor points favor profits.

In estimating without plans, as is the case when one is asked to look over a building, the best plan is to figure per outlet. For example, on an open-work iron pipe job, experience and reference to the cost book will indicate that the cost per outlet is, say, $3.50. To this must be added the cost of feeders and panels. These latter may be put down at $20 erected and feeders, if of average size, at 35 cents per foot. In figuring on drop lights, a certain percentage should be added to the cost per drop. On molding or cleat work the procedure is the same. Where the job is large and warrants the drawing of a plan, this should be done and an analysis made in order to check the prices per unit.

Another way of estimating is to figure the number of lights, and if fairly distributed, average them ten to a circuit. If the building is of average size, it is safe to assume each circuit to be 75 feet long. This will give approximately the number of circuit feet. The rest of the details, such as feeders, panels, etc., can be easily approximated.

When estimating on very large jobs, a circuit-detail analysis sheet, such as is shown in Form B, is often used. The total on this sheet is carried over to the general analysis sheet. These analysis sheets should be carefully filed in a special cabinet. All amendments or changes in the plan should be filed with the original. If a contract is obtained the analysis sheet should be used by the foreman as a basis on which to order material. The sheet should also be compared with the cost books when the work is completed. By this means much valuable information is often obtained. If the job was unprofitable through faults in estimating or through uneconomical management, reference to similar jobs and an analysis of details should indicate where the blame lies.

Estimating on large buildings should be no more difficult than estimating on small buildings; if large jobs are treated as a group of small jobs, the problem becomes quite simple. The cost of labor is naturally perplexing; yet there is no reason why on a straight job in a new building the time should not be practically the same in all cases. A man and a helper should put up so many feet of pipe or molding, as the case may be, in a day, and it is the foreman's duty to get at least that much work out of them. By revising the cost system as new conditions arise, the cost per unit of labor may be made a fairly certain item.

In measuring the number of circuit feet on a plan, a rotometer will save time and promote accuracy. An instrument of this kind made by Kolesch & Co., of New York City, is shown in Fig. 1. The little wheel is caused to run along the circuit lines

FIG. 1.—THE ROTOMETER.

and the dial registers in feet and inches. If the drawings are made to a scale of ¼ inch to the foot, the reading is multiplied by 4 to obtain the circuit feet. As these measurements do not provide for the side wall runs to side outlets and switches it is necessary to add a certain number of feet to provide for these. A good plan is to total the number of side outlets, switches and receptacles, also the number of circuits for runs to panels, and multiply this total by 10 if the ceilings are of medium height. This will provide for runs down to outlet and back to ceiling for a run to another outlet or switch. By the use of the rotometer the number of circuit feet of a large plan can be ascertained in a very short time.

ENGINE ROOM ECONOMIES.

An interesting paper upon engine room economy was read at the recent Hospital Superintendents' Convention in Boston by Chief Engineer Jeremiah C. Long, of the Boston City Hospital. The subject was discussed entirely from the practical standpoint and in a comprehensive way the essentials of good practice were emphasized. In the main the author devoted his attention to the steam ends of the power and distributing plants. At the outset he pointed out the advisability of using high steam pressure in preference to low in transmitting steam to a large group of buildings, especially in cases where the maximum distance covered approximates 1000 feet. It is more economical to carry a pressure of 90 pounds underground in a proper size of pipe than to use 5 or 10 pounds directly in the steam main from the power house. The reducing valves of the heating system will operate as well at one end of the line as the other. The principal losses are due to radiation and friction. With the proper size of pipe the loss due to friction should be about 20 per cent of the radiation loss when the sum of the two is a minimum. Using 90 pounds pressure the loss is probably 30 per cent less than with a pipe twice as large and a maximum of 10 pounds.

A good method of protecting underground pipes not laid in brick ducts is to lay them, covered with asbestos and hair felt in a box made of 2-inch plank. The loss in pipes protected in this way should not exceed 20 per cent of the loss in the case of bare pipes. In connection with the heating system Mr. Long presented the following method of estimating the total square feet of area required in the heating coils: To one-tenth of the wall surface add the full glass surface; to this sum add the cubical contents of the building divided by 100. Then eight-tenths of the total will be the area of coils required for direct radiation, and for indirect radiation multiply by 1.5 instead of by 8.

A large part of the paper was devoted to the discussion of various leaks in plants. All these cost money, but the importance of stopping them is not always appreciated. Losses often occur through the carting away of unburned coal in the ashes, which may arise from poorly set or constructed grates in the boiler furnaces or from the careless permitting of clinkers on the furnace wall. When these are finally dislodged the brickwork sometimes comes down, leaving gaps through which unburned fuel falls into the ash pits. Leaks at pipe joints are frequently encountered and the use of higher pressures has increased the tendency to trouble. Pipe clamps should be used only temporarily, as their constant application tends to produce a patched-up system liable to go to pieces suddenly and cause great trouble. Piston rod stuffing boxes should not be allowed to leak on the supposition that a rod is running free when it is leaking. If an engine is out of line or the piston needs re-centering either will become worse daily if allowed to continue. Some plants allow blow-off cocks to leak just a little to keep them free. This is an expensive policy, and if the water contains scale the deposits are sure to make trouble in time by clogging. With feed water at 40° F. and steam at 100 pounds pressure a loss of 1 pound of coal occurs for each 33 pounds of water passing through the blow-off cock. This applies as well to sterilizers and leaky safety valves.

If the suction valves on a steam pump leak the water is forced back into the tank, and if the discharge valves and check valves on the feed pipe leak water will be forced back into the pump cylinder. This is all useless and expensive work.

A recent test at the Massachusetts Institute of Technology made upon a 6-inch uncovered steam pipe carrying 100 pounds pressure per square inch in a still room at 72° F. gave a loss of 14.5 B.T.U. per foot of length. On this basis a 6-inch bare pipe carrying 100 pounds and 100 feet in length would cause a loss of 87,000 heat units per hour. Allowing 75 per cent efficiency in the burning of the coal, about 8.7

pounds of coal per hour would be required to make good this loss on a calorific power of 14,000 B.T.U. per pound, and in a year at $3.50 per ton the waste would amount to $131.40. The best pipe coverings on the market will reduce this 75 per cent. Another source of loss comes from not using exhaust steam in heating feed water. Live steam should be cut off from steam tables, hot water boilers, stock kettles, dish warmers and sterilizers where such equipment is not in use. In the engineering department of a hospital it is easy for the laundry machinery to be a special source of trouble. Engine leaks, shaky shafts, slipping belts, toothless cogwheels, dry room doors carelessly left open and similar defections do not increase operating economy. Temporary repairs in such cases should not be allowed to become permanent, where new parts can readily be obtained.

The final section of the paper discussed at considerable length the disadvantages of boiler scale. The heat conducting power of scale is in general only about 74 per cent that of iron; 1/16 inch of scale means 15 per cent more fuel; ¼ inch of scale, 60 per cent, and ½ inch, 150 per cent. Under good conditions the temperature of steam at 90 pounds pressure is 320° F. With ½ inch of scale the boiler must be heated almost to a low redness, 700° F., in order to raise steam to 90 pounds. Above 600° iron becomes brittle and granular from carbonization or corrosion to a cast-iron state, and the danger of explosion is great. On a fair average a 125-h.p. boiler would in one year use 20 per cent more fuel than with pure water, if the scale were allowed to accumulate. At 5 pounds of coal per horse-power-hour, 2730 tons would be burned per year of full load running, costing at $3.50 per ton, $9555. The presence of scale would increase this cost by nearly $2000.

Abstracts from Foreign Contemporaries

Protection Against Potential Rises in Transmission Systems—It is well known that in the operation of extra high potential systems of distribution of electrical energy certain conditions tend to the production of dangerous rises in the potential of parts of the system. In order that these may be rendered harmless, it is essential that adequate means be provided to relieve the strain thus thrown on the insulation of the circuit, both as regards transmission lines and machinery. M. M. E. Dusangey, in a paper read before the Société Internationale des Electriciens, discusses the types of apparatus now in use by various Continental companies for this purpose on systems working up to 30,000 volts. As predisposing causes to pressure rises, he mentions (*a*) Atmospheric influences; (*b*) Resonance; (*c*) A sudden break in the circuit; (*d*) Accidental contact with other systems at a higher pressure. The author divides protective devices into two classes: (1) Intermittent; (2) Continuous. Those in the former class are designed to give a momentary discharge to earth by way of a suitable arrangement of spark gaps, having means provided for destroying the resultant arc, and a limiting resistance in the path of the discharge. The second class includes high resistances of liquid or metal wire always in circuit and arranged to pass any excess voltage to earth. These give a continual energy loss, and are known as "over-voltage discharges." The location of such apparatus cannot always be determined originally, but as a general rule protective devices are placed at the entrance and exit of lines to and from sub-stations and power stations, and at the junctions of underground lines and overhead trunks. Other devices are added subsequently at such places as are found necessary. The author proceeds to describe several devices in use. In one case (Société d'Energie Electrique du Littoral Méditerranéan) lightning arresters are arranged with 16 air-gaps in series for 10,000 volts, each gap being 1.25 mm., and having eight carbon resistances of 250 ohms each, arranged in series to earth. For 30,000 volts, 48 gaps and resistance totalling 8000 ohms, are in use. As an "over-voltage discharger" the same company uses nine air-gaps of 1.5 mm. in series, with 10,000 ohms resistance in three sets arranged in Δ between the wires. Lightning arresters of the horn and magnetic blow-out types are also in use. When used as lightning arresters by the Société d'Energie Electrique de Grenoble et Voiron, a resistance of 8000 ohms (wet sand) to earth and one air-gap of 7 mm. are in combination for 15,000 volts. The same horn arresters, when connected as over-voltage dischargers, have 14,000 to 15,000 ohms in series. Another company (Société Hydroélectrique de Vizille) uses earthenware tubes filled with water as limiting resistances. These are 80 cms. long for 10,000 volts. Still another company (Cie Vaudoise des Forces Motrices des Lacs de Joux et de l'Orbe) arranges for a jet of water from a tank to fall into a metal cup connected to the earthed plate of a horn arrester. The water flows from these cups into a second tank kept at earth potential. A modification of this device (Société Hydro-électrique de Guiers) used as an over-voltage discharger, is an arrangement of three water jets from an earthed iron pipe, playing on terminal plates connected one to each line. The author concludes with the following suggested arrangement of protective devices: Outside the station, protected from the weather, lightning arresters, of either the horn or magnetic blowout type, are connected between each line and earth. Between this and the station, spark gaps are arranged in series between each wire and earth (by way of high resistance) to act as an over-voltage discharger; this is arranged to operate at 50 per cent. excess pressure. Inside the station a continuous discharge of 0.2 to 0.5 of an ampere takes place by way of a high resistance to earth. Between this and the switches kicking coils are inserted, and again between the switches and machines similar kicking coils. Still another discharger of horn arresters and non-inductive resistances is connected in Δ between the switches and machine kicking coils.

Electric Ignition Device for Gas Engines.—In electrical ignition devices for internal-combustion engines using charges of varying thermal value, it is of great importance that the time of firing should be capable of variation according to the rate of inflammation of the fuel used. An arrangement devised for this purpose is described in the *Mechanical Engineer*, and consists of an improved trip mechanism for use with a low-tension magneto with an oscillating armature. Fig. 1 is a view in side elevation of the mechanism. The armature of the magneto, which is of the usual low-tension type, is actuated by a bell-crank lever A through a rod A_1. The bell-crank lever is moved through the necessary arc to produce the oscillation of the armature by means of a reciprocating rod B pushing—during a portion of its stroke—against a trip lever C pivoted at C_1 and connected to the rod D at D_1, the reciprocating rod B being driven by a crank E on the half motion shaft X of the engine. When the point B_1 of the reciprocating tripping rod B moves below the point of the trip lever C the springs on the magneto or an auxiliary spring such as F operate to pull the bell-crank lever A back to its normal position, and at the same time cause the end of the rod D to strike against the contact lever G of the sparking device and thus cause contact to be broken in the

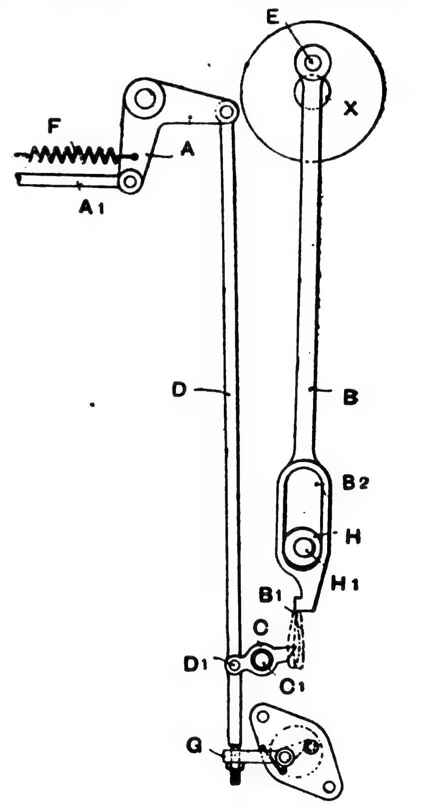

FIG. 1.—ELECTRIC IGNITION DEVICE FOR GAS ENGINES.

cylinder whereby a spark is produced. The reciprocating tripping rod B is supported near its tripping point by a pin working in a slot B_2. By moving the pin transversely with respect to the line of movement of the rod B the time of the release of the armature and consequently of the spark can be varied as desired. A convenient method of accomplishing this regulation is to make the pin in the form of an eccentric H capable of being rotated on the fixed pin H_1, thus raising or lowering the orbit of the travel of the trip point B_1 of the reciprocating tripping rod B.

Motor-Driving Arrangement for Lathes.—The accompanying illustrations show a recent design of lathe headstock directly driven by means of an electric motor. In this design the lathe spindle and the first and other motion shafts are easily accessible for the adjustment or removal of their bearings; the motor is so arranged as not to interfere with the accessibility of the various parts of the lathe mechanism, and so as to occupy a minimum of space, while at the same time the arrangement of the gearing is such that the usual lateral movement of the motor spindle while running is allowed for. Referring to the illustrations, for which we are indebted to the *Mechanical Engineer*, the face plate A is driven directly by a pinion B secured to the back of the face plate. A transverse shaft C passes beneath the lathe spindle D, to which is directly coupled by an ordinary flange coupling E, the electric motor F. This first transverse shaft C carries a pinion G gearing with a pinion H on a second shaft J. The shaft J also carries a bevel pinion, K, gearing with a bevel wheel, L, fast upon a shaft, M, and which may be termed the first motion shaft of the lathe. Since the transverse motor shaft, C, drives through spur gearing, it is obvious that it may be allowed end play sufficient to give the motor armature the endwise movement necessary. With this end in view the pinion G is made slightly narrower in face than the pinion H, the teeth of the former thus remaining laterally within the teeth of the latter notwithstanding the endwise movement. The end of the shaft C remote from the motor and the corresponding end of the shaft J are carried in a bracket N. This bracket is shown more clearly in Fig. 2, and its lower depending end is bolted to a standard O cast on the headstock base P, and it is so shaped as to form one-half of the journal of each shaft C J, the other half of each journal being formed by caps, Q R, while, as shown in Fig. 3, an aperture is formed in its lower depending part for the passage of a shaft S, forming part of the usual lathe gearing. The inner end of the shaft J is carried by a bearing secured to the top of a second pedestal T cast on the headstock base P, this bearing being also provided with a cap U. The "first speed" of drive for the lathe passes through a pinion V upon the first motion shaft M directly to the face plate pinion, B, and the pair of pinions G H, the bevel wheel L, and pinion K. The other speeds desired are obtained by the use of pinions of various proportions upon the first motion shaft and upon the shaft S, which is beneath and parallel therewith, connecting and disconnecting devices (not shown) being employed and the ultimate drive taking place in all cases through the faceplate pinion B and the pinion V on the first motion shaft M gearing therewith. The motor F, driving the first transverse shaft C, is directly coupled to that shaft by the coupling E and is arranged at the rear of the lathe. The arrangement possesses several advantages over those ordinarily used, in that it allows of the placing of the motor to the rear of the lathe where it is out of the way, and where, owing to its position, it may be arranged so closely to the lathe that little if any greater width is required. Further, since the transverse motor shaft C is below the spindle D, the bearing of the latter may be adjusted or it may be bodily removed without interfering with the driving gear; while the first motion shaft M, the second transverse shaft J, and the transverse motor shaft C may all be removed successively in the order named, or their bearings be adjusted in their original position.

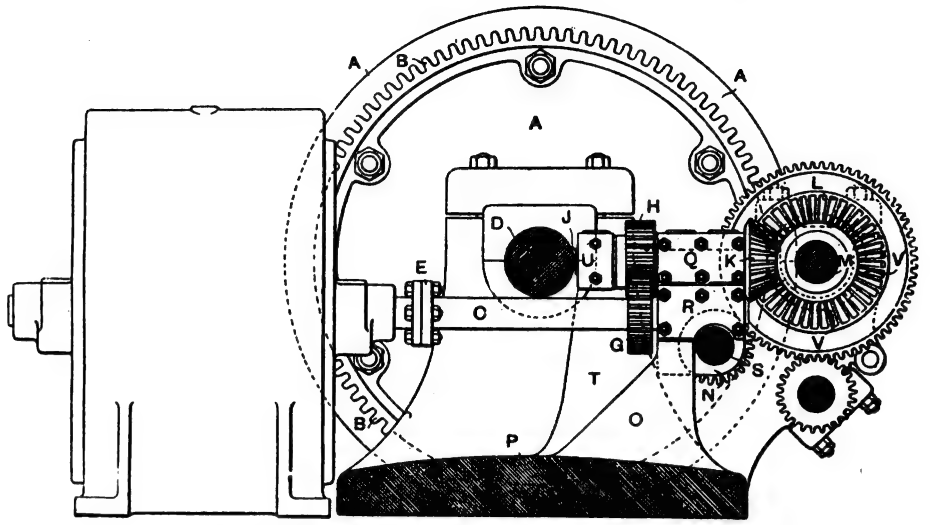

FIG. 3.—MOTOR-DRIVING ARRANGEMENT FOR LATHES.

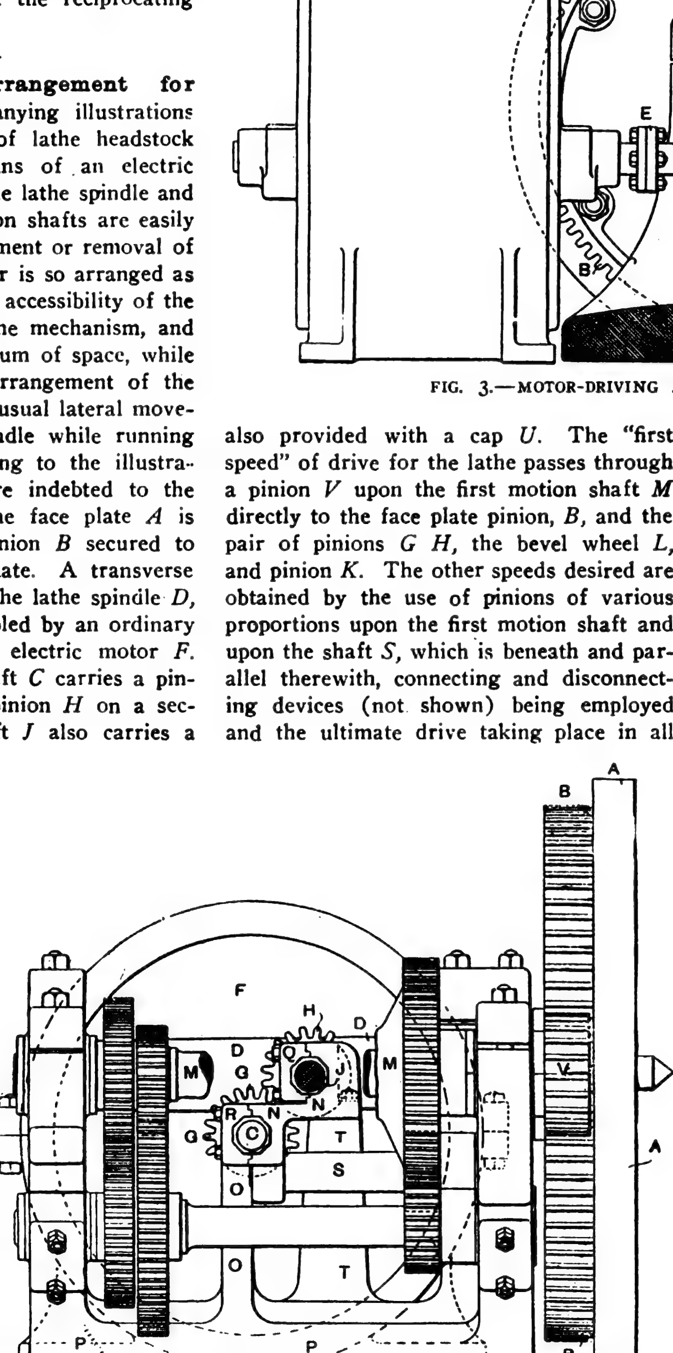

FIG. 2.—MOTOR-DRIVING ARRANGEMENT FOR LATHES.

Calculations of Mean Spherical Candle-Power.—J. Wild contributes to a recent number of the *Electrical Engineer* an account of a method by which the mean spherical candle-power of an ordinary incandescent lamp can be calculated with an error not greater than ½ per cent. from measurements taken at angles differing by 30 degrees. Measurements taken every 30 degrees would not suffice in the testing of an arc lamp or any source of light the candle-power of which undergoes great changes at small angular differences, but for ordinary incandescent lamps the mean spherical candle-power calculated every 30 degrees is sufficiently accurate for ordinary purposes. The method is simply to multiply the measured values of the mean circular candle-power at angles of 0, 30, 60 and 90 degrees above and below the horizontal with certain factors and to add the products to obtain the mean spherical candle-power. These multiplying factors with which the circular candle-power at different angles is to be multiplied are as follows:

	Multiplying Factor.
Angle 90 deg. above horizontal	0.017
" 60 deg. above horizontal	0.1295
" 30 deg. above horizontal	0.224
" 0 deg. horizontal	0.259
" 30 deg. below horizontal	0.224
" 60 deg. below horizontal	0.1295
" 90 deg. below horizontal	0.017

Economy of Arc Lamps.—The *Elektrotechnische Zeitschrift* publishes a long discussion of the economy of various types of arc lamps with special reference to the number connected in series. It is pointed

out that there are a great many different factors besides energy consumption which must be taken into account in determining the economy of a given type of lamp, and the article contains a number of tables and diagrams comparing the economy of the different lamps with respect to energy consumption alone. The following table gives the watts consumed in order to obtain 2,000 Hefner candles with ordinary carbons and with flame arc lamps:

Ordinary Carbons.		
110 volts,	2 lamps in series,	1250 watts.
110 volts,	3 lamps in series,	1060 watts.
220 volts,	4 lamps in series,	1575 watts.
220 volts,	5 lamps in series,	1350 watts.
220 volts,	6 lamps in series,	1350 watts.
Flame Arc Lamps.		
110 vols,	2 lamps in series,	800 watts.
220 volts,	4 lamps in series,	950 watts.
220 volts,	5 lamps in series,	1000 watts.

These results are of interest when lighting installations are planned for towns of medium size. Many customers, for instance, can use two or three arc lamps, but no more. At 220 volts it is necessary to use a larger number of lamps, whereby the cost of installation is increased. Moreover, with the same consumption of energy less light is obtained. Further, it will be noticed that the connection of six lamps in series is not superior to five lamps. It may be different, however, if in a larger installation a certain number of lamps is prescribed. If sixty lamps are required, it will be possible to get more light by connecting six lamps in series than five in series. For instance, 13.2 kilowatts give in such a case 20,000 Hefner candles for ten circuits each containing six lamps in series and each consuming 1.32 kilowatts. The same energy gives 16,800 Hefner candles in twelve circuits each containing five lamps in series and each consuming 1.1 kilowatts. With enclosed arc lamps the energy consumption is almost always higher, enclosed lamps being superior only for small intensities of light. The whole situation is, however, changed if the consumption of carbons, cost of attendance, interest and depreciation are considered. It is shown that for small intensities of light the enclosed lamp is quite economical. The connection of six lamps in series at 220 volts is no more economical than a connection of five. For small light intensities and short hours of burning, four lamps in series may be more economical than six lamps. With the flame arc, four lamps in series at 220 volts are not less economical than five lamps in series. The flame arc lamp is to be taken into consideration only for great light intensities, such as 1000 Hefner candles at 110 volts and 2000 Hefner candles at 220 volts, but for all practical conditions the flame arc is more economical than other types of lamps. The superiority of three lamps in series over two lamps in series appears only at longer hours of burning or with greater light intensity. In every respect 220 volts appears to be less economical than 110 volts for arc lamp installations. There is no difference between alternating and direct current with respect to flame arcs. Ordinarily arc lamps, however, when operated with alternating current, three in series, at 110 volts, consume about 60 to 70 per cent more energy for the same light than with direct current, three lamps in series, and 40 to 50 per cent more energy than with direct current, two lamps in series.

Brush-Holder.—The London *Electrician* contains an illustrated description of the brush-holder shown by Fig. 4 herewith. A spiral spring serves to exert a uniform pressure of the brush on the commutator and this is enclosed in a cartridge-shaped arm of the brush-holder and thus pro-

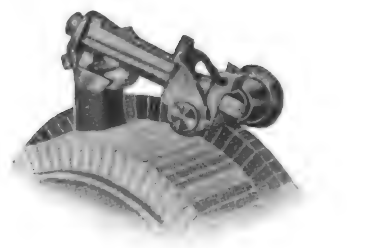

FIG. 4.—BRUSH-HOLDER.

tected from dust and accidental injury. The milled nut, *A,* serves to adjust the pressure of the spring. The latter presses against a small plunger which abuts at one end against the face of the cam, *B,* clamped to the brush spindle, *C,* while the other end of the spring passes through the hollow nut, *A.* When the brush wears away sufficiently to be of no further use, a small projection, *D,* coming in contact with the head of the plunger prevents any further descent of the brush. The metal parts of the brush-holder cannot, therefore, damage the commutator. The cam, *B,* is of such shape that the brush when lifted off the com-

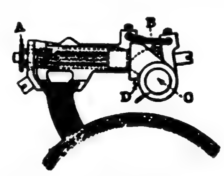

FIG. 5.—BRUSH-HOLDER.

mutator remains in this position, thus allowing any adjustments to be made and facilitating the renewal of the brush.

Direct-Current Power Transmission—In a lecture delivered before the British Association for the Advancement of Science on "The Distribution of Power," Prof. Ayrton spoke in favor of the use of high-tension direct-current for power transmission and distribution. Direct-current possesses an advantage over alternating-current in that there is less liability of breakdown of insulation, since from the point of view of economical transmission 60,000 effective volts alternating is the same as 60,000 volts direct, yet from the point of breakdown of insulation 60,000 effective volts alternating is as bad as 85,000 volts direct, and may be worse than 100,000 volts direct-current. There is, further, with direct-current, no question about self-induction reducing the current, and hence, no objection to putting the conductors as far apart as the risk of brush discharge may necessitate. There is also no question about capacity current nor resonance troubles, etc. The author also states as another advantage of direct-current transmission, as carried out by Thury, that it is the current which is kept constant and the voltage which is automatically raised when the demand for power is increased. It is easier to maintain constancy of the current flowing along a long circuit than to prevent the bobbing up and down of the voltage at the distant end of a long transmission line and "that irritating dancing of the lights." Constant current has also its well-known disadvantages, but these would not come into play if the constant current were not taken into houses, etc., but were used to drive motor-generators in sub-stations.

Some Recent Electrical Patents

Motor Controller.—Figs. 1 and 2 illustrate diagrammatically the feature of a patent recently issued to Mr. Samuel S. Neu, of New York, covering an improved motor-starter, this feature consisting of an arrangement for opening the shunt field circuit of the motor whenever the armature is shut down, the opening of the field circuit taking place after the armature has been brought to rest by the dynamic braking effect due to close-circuiting the armature with the field excited. The diagrams show two methods of accomplishing the desired result; in Fig. 1, the field circuit is opened by the lever, under the influence of a helical spring, after it has been

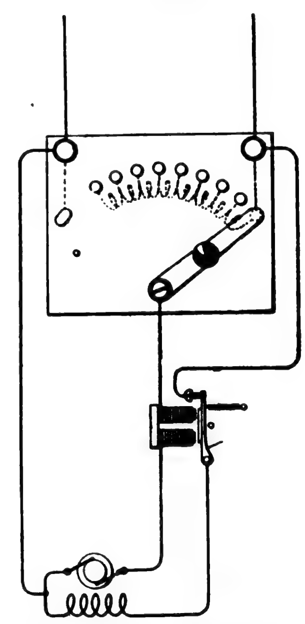

FIG. 1.—MOTOR CONTROLLER.

released by the magnet in the armature circuit; in Fig. 2, the starting arm, when thrown to the off position by its spring in the usual manner, first short-circuits the armature by resting on the contact on which it is shown in the diagram, and then opens the field circuit by moving the switch lever, *j,* away from its contact stop. In Fig. 1, the armature is short-circuited in the same way, the starting lever resting on the button, and the current flowing in the armature due to its generator action while

running on its own momentum holds the field circuit closed; as soon as the armature current dies, the magnet releases the

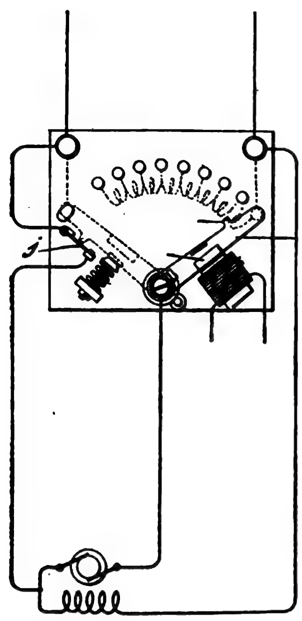

FIG. 2.—MOTOR CONTROLLER.

armature, thereby opening the field circuit. Patent No. 800,816.

Metallic Wire Conduit.—Several efforts have been made to produce a metal

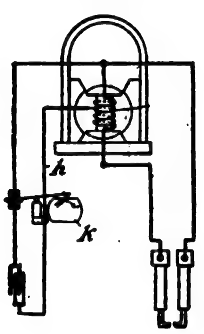

FIG. 5.

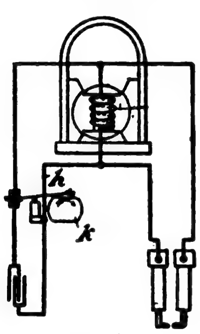

FIG. 6.

interior conduit which would have all of the mechanical merits of the old wooden moulding without its demerits from the insurance and æsthetic standpoints. The accompanying illustrations, Figs. 3 and

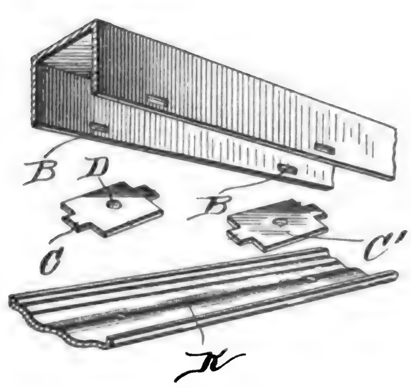

FIG. 3.—METALLIC WIRE CONDUIT.

4, taken from a patent issued to Mr. Henry C. Ayres, of Greenville, Ohio, show one of the latest of these devices. The conduit comprises a metal trough, *A*, having short slots (*B*, *B*) punched in its sides at suitable intervals; a series of shelves, *C*, having end lugs to fit in the slots, and a cover, *K*, to close the under side of the trough. The shelves support the wires, as indicated in the cross-sectional view, Fig. 4, and also provide a means of holding the cover in place, the latter being held on

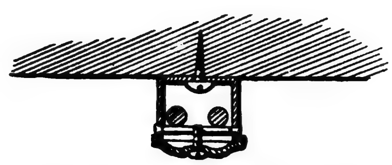

FIG. 4.—METALLIC WIRE CONDUIT.

by screws tapping into the holes *D*, *D*, in the centers of the shelves. Patent No. 800,052.

Magneto for Gas Engine Ignition.—The disadvantages of having to renew primary battery cells and recharge storage cells have stimulated inventive effort along the lines of magnetic generators for this class of service. One of the arrangements recently devised and patented by Mr. Gottlob Honold, of Stuttgart, Germany, is illustrated herewith. Mr. Honold's method consists broadly of short-circuiting the magnetic armature until the moment for ignition and then releasing the short-circuit abruptly while the armature winding is in a position of maximum activity. The contact which short-circuits the armature is bridged by a condenser in order to enhance the effect of releasing the short-circuit.

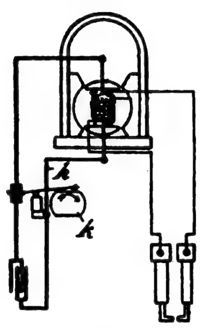

FIG. 7.

Fig. 6 shows this arrangement in its simplest form, the entire armature winding being short-circuited by the contact *h* until it is raised by the timing cam, *k*. In Fig. 5, only half of the winding is affected, and in Fig. 7 two windings are employed, one a relatively low-potential winding which is short-circuited until the ignition moment, and the other of many turns of finer wire which is connected to the igniter plug and is affected by the first winding transformer fashion. Patent No. 802,291.

NOTES.

Central Battery System "Discovered" in Germany.—The Germans have progressed telephonically to the central energy stage. The whole of the Berlin telephone network is being reconstructed and adapted to the central battery system, which has been in use in this country for many years. "The most striking feature of the new telephone apparatus," writes a correspondent, "is the absence of any crank for actuating the signalling apparatus, it being only required to take the receiver off the hook, when the current from the exchange battery lights up a small glow lamp there. By reciprocating movements of the hook, flickering signals can be produced at the exchange."

Wireless Telegraphy and the President's Trip.—The suggested plan of the President to return from New Orleans on one of the Government war vessels, keeping in touch with affairs on shore by wireless telegraphy during the four days' voyage, only furnished another illustration of the way in which electricity overthrows antiquated precedents. There has long been a tradition that no President should leave United States territory while in office, and we recall no other instance in which this has been done. In some quarters there is held the idea that the deck of a warship is Government soil, and that President Roosevelt's trip violates no tradition after all. However that may be, wireless telegraphy furnishes the means of keeping the Chief Executive's hand upon the helm with essentially the same grip which is manifested at the White House itself, so there would seem to be no occasion for alarm on the part of those who fear that the Ship of State will be striking the rocks during the absence of its Pilot from the wheel-house. It is just a neat example of remote control, which every electrician knows to be perfectly feasible.

The Fruits of Municipal Control.—A correspondent throws some light on the inner workings of electric plants under municipal control, in the following letter, names being omitted for obvious reasons:

> You may state through the columns of your paper that I have resigned as superintendent and manager of the ———— Municipal Electric Light plant and have accepted a similar position with the ———— Electric Light & Power Company. The plant at ———— while under my management was prosperous; but became involved in politics, and is fast going down hill. Mr. ———— was appointed in my place; but Poor Man! he only lasted four days; burnt out a machine, got hold of a live wire and they carried his body home on a stretcher.

According to a clipping from a local paper which our correspondent enclosed, it appears that this victim of circumstances had been employed as a fireman and engineer. His chief had asked for the munificent salary of $70 per month, and the trustees tried to hold him with a compromise salary of $65, but without avail. The fireman was then placed in charge with the above unfortunate result. The plant was shut down and the town was without light for some time. An inexperienced man finally essayed to take charge and the service has since been abominable. The clipping ends with these words: "It has been proved that trying to run thousand-dollar machinery with fifty-cent help isn't economy and one of these days the board will come to realize it."

Kansas Gas, Water and Electric Association.—The eighth annual meeting of the Kansas Gas, Water, Electric Light and Street Railway Association was held at the Mercantile Club, Kansas City, Kansas, October 13 and 14. The election of officers for 1905-6 resulted as follows: President, W. E. Sweezy, of Junction City, Kan.; first vice-president, S. W. Sterrett, of Kansas City, Kan.; second vice-president, F. D. Aley, of Wichita, Kan.; third vice-president, C. L. Brown, of Abilene, Kan.; secretary and treasurer, James D. Nicholson, Newton, Kan. The new executive committee consists of E. Springer, W. R. Morrison and J. C. Nicholson.

International Exposition at Milan, Italy.—In order to appropriately celebrate the completion of the Simplon tunnel, an international exposition under royal patronage will be held in Milan, Italy, from May to November, 1906. This will be the largest European exposition ever held outside of Paris. Every branch of art, science, agriculture and the industries will be given ample space and adequate opportunities for exhibition. The entire fair will cover an area of more than 10,764,200 sq .ft., of which one-quarter will be covered by buildings. Nearly every country in the world will be represented. The commissioners for the United States section are J. H. Gore and L. S. Ware. Mr. Gore's address is, care of George Washington University, Washington, D. C.

Illinois State Electric Association.—At the sixth annual convention of this association, held at the National Hotel, Peoria, Ill., October 5 and 6, the following officers were elected: President, D. Davis, Litchfield; first vice-president, J. N. C. Shumway, Taylorville; second vice-president, E. L. Brown, Elmwood; third vice-president, E. McDonald, Lincoln; fourth vice-president, E. H. Gray, El Paso; treasurer, W. J. Day, Bement; secretary, H. E. Chubbock, La Salle. Executive Committee—W. B. McKinley, Champaign; E. G. Schmidt, Springfield; F. J. Baker, Chicago; S. S. Davis, Moline; E. B. Hillman, Quincy.

Underwriters' National Electric Association.—The annual meeting of the electrical committee of the Underwriters' National Electric Association will be held in the rooms of the New York Board of Fire Underwriters, 32 Nassau Street, on Wednesday, December 6. As in the past, the meeting will be open to all interested in the matter of rules for the installation of electric wiring and apparatus, as contained in the National Electric Code. Reports of committees and all suggestions for changes in the code to be acted on at this meeting should be in the hands of the secretary, C. M. Goddard, by November 5, in order that they may be printed for the meeting. The secretary's address is 55 Kilby St., Boston, Mass.

CENTRAL STATION ENGINEERS—XIII.

W. W. Freeman.

W. W. Freeman, vice-president and general manager of the Edison Electric Illuminating Company, of Brooklyn, N. Y., was born in Exeter, Ontario, Canada, on June 8, 1872. He was educated in the grammar and high schools of Canada and began his business career on coming to New York in February, 1889. He became at that time stenographer and secretary to the general manager of the Edison Electric Illuminating Company, of Brooklyn. The company was just beginning operations, having obtained its charter from the City of Brooklyn but a few months prior to that date. Mr. Freeman was, therefore, the first employe of the company, outside of the executive officers, and thus became familiar with the history and the operations of the company in all its departments as the business developed and the company expanded. After serving for about two years in the capacity referred to, he was promoted to the position of assistant to the secretary and treasurer of the company retaining this position until January, 1895, when he was made assistant secretary. In January, 1898, Mr. Freeman was appointed secretary of the company and given entire charge of the conduct of the business, including the solicitation of new business, the dealings with the company's customers and with the public, in addition to executive duties. Early in January, while still retaining the office of secretary, he was also appointed treasurer, and elected a director. Last June he was elected vice-president and general manager of the company, retaining the office of treasurer, but resigning that of secretary. Mr. Freeman is also at the present time vice-president and treasurer of the Kings County Electric Light & Power Company: secretary and treasurer of the Amsterdam Electric Light, Heat & Power Company; director and treasurer of the Electrical Testing Laboratory, and president and treasurer of the Rubber Balloon Company of America. He is also a member of the Manufacturers' Association of New York, and a member of the Brooklyn Club, Crescent Athletic Club, Ridge Club, and also president of the Congregational Club of Brooklyn.

W. W. FREEMAN.

Western Association of Electrical Inspectors.—A meeting of the Western Association of Electrical Inspectors was held in the Assembly Rooms of the Chicago Underwriters' Association on Thursday and Friday, October 5 and 6. The secretary's report indicated a membership of one hundred and fourteen, sixty-six of whom are connected with municipal departments, forty-six serve insurance interests and two are employed by public service corporations not engaged in the electrical business. Since its organization the association has issued eight bulletins and seven committee reports, consisting in all of fifty-one pages of printed matter. Out of the large number of recommendations for changes in the National Electrical Code, the association only saw fit to endorse six. Several interesting committee reports covering various phases of electrical inspection work were discussed. In view of the short time permitted for the consideration of subjects allotted to special committees, the general excellence of reports submitted to the association has been a source of great encouragement to its officers and members. Four additional special committees were appointed to undertake the investigation of the following subjects: Electric crane wiring, underground systems, induction motors, and co-operation with National Electrical Associations. The next meeting is scheduled to be held at Indianapolis, Ind., in October, 1906.

Michigan Electric Association.—This association held its second annual meeting at the Griswold House, Detroit, Mich., on October 10. The papers read and discussed were as follows: "Rates," by W. F. Kingan, Detroit; "High Efficiency, High Candlepower Incandescent Lighting Units," by Francis W. Willcox, of Harrison, N. J.; "Constant-Speed Motors and Centrifugal Pumps: Their Advantage to Waterworks Plants," by P. D. Denman, Detroit; "Uniform Accounting and Its Relation to Cost Determination," by S. G. Carleton, Sault Ste. Marie, Mich.; "Electric Heating Devices," by H. W. Hillman, Schenectady, N. Y., and "Lightning Arresters," by Robert S. Stewart, Detroit. The new officers of the association are: President, William Chandler, Sault Ste. Marie; vice-president, F. S. Hubbell, Milford; secretary and treasurer, A. C. Marshall, Port Huron.

AMERICAN ELECTRICIAN

WITH WHICH IS INCORPORATED
Electrical Industries.

CECIL P. POOLE, Editor.

Issued on the first of each month by the

McGraw Publishing Company

Address all business communications to AMERICAN ELECTRICIAN, *114 Liberty Street, New York. Matter intended for publication in the reading columns should be addressed to the editor.*

Subscription price, $1 per year, postage prepaid, in the United States, Canada, Mexico and Cuba; $2 in all foreign countries. The date on wrapper shows when subscription expires. Subscribers should give their old as well as their new address when requesting a change in address. This should be received a week in advance of the desired change. No copies are kept on sale beyond fifteen months from date of issue, except in bound volumes.

Advertising rates sent on application. Advertisements received for insertion up to the 25th of the month prior to date of publication. Changes in standing advertisements should be received not later than the 15th of the month to insure their insertion in the next issue.

Remittances should be by check, New York draft, express or postal money order, payable to AMERICAN ELECTRICIAN.

Entered in the Post Office at New York as second class mail matter.

Vol. XVII. NOVEMBER, 1905 No. 11

THE AMERICAN ELECTRICIAN *has the largest circulation of any electrical journal published. Of this issue,* 18,000 *copies are printed. The total number of copies printed so far this year is* 198,000, *or an average of* 18,000 *per issue.*

CONTENTS.

Some Lessons from a Small Plant.

It is always interesting to inspect a plant with the idea of ascertaining at what points its production economy suffers, or of noting especially effective methods of operation. While in many cases conditions which are not apparent on the surface determine the wisdom of a design, it is generally possible to pick out various features in a given layout of machinery which should not be overlooked in other propositions. The idea prevails in some quarters that the study of old plants is of little importance in comparison with the analysis of new designs, but in the effort to secure high efficiency of operation there is surely as much profit for the engineer in examining abnormal specimens in the power station line as there is for the physician in the study of disease. That more thorough studies of older plants are needed is evidenced by the defects which are frequently permitted to appear in even the most modern installations.

A suggestive installation is the local electric light plant of a New England town of about 4,000 population. In the community served, the sale of electricity for lighting exceeds the sale of gas by the ratio of 7 to 1, and the gross earnings per capita are $5.09, a figure surpassed by few of the largest stations in that state. With such excellent receipts there should be the opportunity, of rolling up attractive net earnings by the reduction of the operating ratio to the lowest point consistent with proper maintenance. During the last fiscal year the gross earnings of the electric plant were $19,462, and the operating expenses $11,720. Of the latter, $6,425 was expended at the station. The equipment consists of two 150-h.p. boilers and 350 kilowatts of generating machine, all the units being of the old 133-cycle type, belt-driven from non-condensing engines. Such a combination certainly promises little in the way of fuel economy, and the resulting inefficiency of plant operation becomes all the more striking when the station labor account is considered. No figures are at hand covering wages, but as the power house force consists of one day man and one night attendant, their combined salaries probably do not exceed 15 per cent. of the total operating expenses. The duties of engineer and firemen are both performed by a single individual, who signals for help with the station whistle in case anything goes wrong.

The coal handling scheme in the plant is decidedly uneconomical, although one would not expect mechanical conveyors and automatic stokers in so small an installation. The point of loss lies in the needless extra labor of shoveling between the coal cars and the grates. Coal is brought to the plant in the railroad cars and shoveled upward over the sides of the cars into out-of-door bins. Three men are often employed in this work, and their wages enter into the cost per ton delivered regardless of whether they are on the railroad, the coal dealer's or the electric light company's pay roll. From the bins the coal is shoveled by the regular fireman into a hand barrow, wheeled a distance of some 40 feet to the boiler room, dumped upon the floor and finally shoveled into the furnaces. Various other faulty features of operation might be cited, but it will serve our present purpose to touch upon but two points. In the boiler room the high-pressure piping leading to the feed pump was found to be uninsulated, leading to a waste of heat, and consequently of fuel, while in the dynamo room some of the wiring was discovered to be in a bad tangle capable of causing serious trouble.

The Outlook for Heavy Electric Traction.

For certainly a decade electrical engineers have looked forward with the most intense interest to the time when the steam locomotive shall be driven from its place in trunk line service. That day may still be far ahead, but the purchase of twenty-five alternating-current locomotives at $30,000 each by the New York, New Haven & Hartford R. R. as announced at the Philadelphia Convention of the American Street Railway Association, indicates that the problem is in a fair way to be solved. The large developments in process in the terminal service at New York on the part of the New York Central and Pennsylvania lines show conclusively that the steam locomotive—admirable machine as it is in many respects—is doomed to extinction within the largest centers of population, and that the suburban service in the near future in and about progressive metropolitan circles will be handled by electricity in a manner that will be a revelation to the traveling public and a source of enlarged financial satisfaction to the directors and stockholders of the transportation companies. Now comes the New Haven with a proposition of such breadth and far-sighted departure from previous standards that our acceptance of the triumph of electricity in suburban service seems but the assured anticipation of still greater progress.

It is a matter of small significance that these new 78-ton 1,600-h.p. machines are to be operated for the present on the New York Central's direct-current lines between Woodlawn and the Grand Central station. The ability of these locomotives to operate upon both alternating and direct-current circuits is indeed an achievement of which single-phase commutating motor designers may be proud, but the key to the trunk line problem lies in the production of so large a motor as 400 horse-power, with its armature directly connected to the shaft without gearing, and multiple-unit control with alternating-current external supply in the neighborhood of 3,000 volts.

Central Station Publicity.

Methods of securing new central station business have frequently been discussed in these columns, and it is gratifying to note the progressive efforts now being made in many quarters to increase the electrical output of both large and small plants. Unless it be the question of fighting municipal ownership, there is perhaps no other matter now before central station men commanding more widespread interest than does the problem of publicity. It is certainly of sufficient importance to justify a few additional comments at this time.

The variety of ways in which a central station manager can attract public attention to his service are, of course, multitudinous. Perhaps the best advertisement of all is a quality of service which surpasses that of other communities in the same general vicinity. People are constantly traveling about from place to place in these days of automobiles and interurban electric railways, and during the hours of darkness the contrast between the well-lighted streets and stores of one town and the run-down, gone-to-seed appearance of a neighboring town served by decayed Welsbachs and sputtering gas or oil street lamps is certainly too great to pass unnoticed. It is not an easy matter to estimate the influence of first-class street and commercial lighting upon the development and prosperity of a given community, but there is no possible doubt that well-illuminated thoroughfares and buildings are essential to the lasting prosperity of any city, large or small, which is face to face with modern competitive conditions. It means a great deal to a town whether commercial travelers "size it up" as a "dead" or a "live" community, and while something besides electric lights is needed to establish and maintain a reputation for business aggressiveness, there are very few places of a solid, successful character which are served with poor illumination. We have no desire to provoke anything but friendly rivalry between central stations in the same general vicinity in suggesting that a little local newspaper emphasis of good service is sometimes worth much more than it costs. First, last and all the time, the central station manager must remember that the more the public can be brought to realize the good service it is receiving the less chance there is for the politician and the municipal ownership cranks to injure his business.

The Edison companies are doing a great deal to educate the public in the advantages of electric light and power service. In its last monthly bulletin, for example, the Boston Edison Company, brings out a number of points which ought to be generally appreciated by and brought home to the consumer. The company considers the state in which we should find ourselves if we had no incandescent lamps, but were thrust back into the gas-kerosene era, choking over the sulphurous fumes of eight-day matches, breathing the vitiated air of homes illuminated by open flames, sweltering under the heat of gas chandeliers in churches and theatres, and at night wandering along streets shrouded in darkness. To lose the incandescent lamp would be one of the greatest calamities the world could know. The company points out the decreased expense for redecorating where electricity is used and states that real estate agents testify that an electrically lighted building need not be redecorated but once in two years, at the least, compared with about twice as often in gas or oil lighted rooms. Owners are on record who allow tenants a lower rent in consideration of their using electricity instead of gas or oil. These points are well appreciated by central station managers, but that is not so much the issue as the education of the public to the more extended use of electricity. Publicity in some form is the only method of accomplishing this result.

An effective means of attracting the attention of the discriminating public consists in the employment of an architect in the erection of power plant and sub-stations. The day has passed when permanent engineering structures have any excuse for being of hideous appearance. The pumping stations of the Metropolitan Water Board, in the suburbs of Boston, have long been famous for their architectural attractiveness, and the work of the building designer in such plants as the Subway and the Kingsbridge power houses and the Waterside Edison station in New York proves that the central station may be no less architecturally pleasing than the picture gallery. The new plant of the Cambridge (Mass.) Electric Light Company is another example of the erection of a power house on the border of a superb riverside parkway, the building being in such harmony with its ultimate surroundings as to add to the landscape's attractiveness. Questions of this kind cannot be well expressed in dollars and cents, but it is certain that money expended to establish a public reputation for solidity, permanence and sagacious adaptation of means to ends is well worth while.

The power field is so vast that no central station man ought ever to be at a loss to find a suitable subject for his advertisements. All that is necessary is sufficient knowledge of different kinds of business to enable the particular advantages of electricity to be pressed home suitably in each case. Thus, in a chemical laboratory the cleanliness and compactness of the electric motor and light commend themselves, while in the large coffee and spice grinding house the ability of the motor to operate under the severe conditions of pepper and other dust needs to be brought forward. Certain advantages are common to all businesses. For example, the proper use of electricity in a formerly gas lighted store almost immediately produces a greater volume of trade, a better average class of business and freer buying attitude on the part of customers.

Finally, the application of the electric sign is a whole field in itself. In its haste to supply customers with signs a station should not overlook its own advertising. All through the territory supplied with Boston Edison current, one finds the poles each labeled with a neat tin plate marked "Edison Light" in white letters upon a black background. A drawing of a lighted incandescent lamp occupies the center of the plate, and the whole affair is so neat that its presence is permitted even in the heart of the Metropolitan Park system—a privilege which we believe is extended to no other advertiser. The Walden Electric Light Company uses an attractive illuminated sign at its offices, consisting of incandescent lamps disposed in the form of a horse-shoe magnet, with the company's name in the center. All these points count in the aggregate, and are in part responsible for the enormous extension in the use of electricity common to progressive communities.

CONSTRUCTION OF A CONDENSER FOR A JUMP-SPARK COIL.

In the October number, instructions were given for constructing a jump-spark coil for gas-engine ignition purposes, and while this coil will give good results at the terminals of the secondary when current is supplied to the primary, its efficiency is materially increased by the addition of a condenser. Such a piece of apparatus is made of tin-foil, each sheet being insulated from the next by some dielectric.

The capacity of a condenser is expressed by the formula: $C = K \div d$, in which K is a constant depending on the specific inductive capacity of the dielectric; A, the total area of the tinfoil, and d the distance between one sheet and the next. It is evident, therefore, that the capacity depends directly on the nearness of the sheets to each other and the value of the dielectric constant for the material separating them, so that the more compact the condenser, the greater its efficiency; and this should be borne in mind when assembling the condenser.

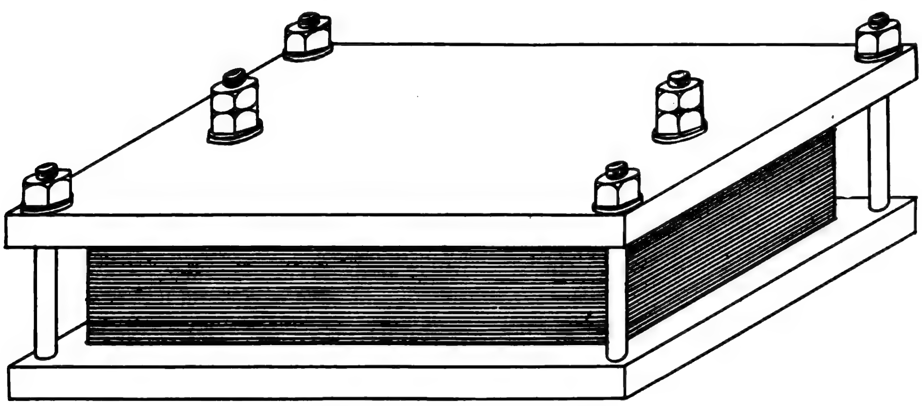

FIG. 1.—ELECTRIC CONDENSER.

A condenser suitable for the jump-spark coil described last month may be made of 60 sheets of tin-foil, 3½ ins. by 9 ins. Any other size might be used provided the area of the tin-foil in the completed coil is the same, the size given being chosen so as to enable the builder to fasten the condenser to the base of the coil. The tin-foil may be purchased from dealers in electrical instruments, or directly from the makers. Paraffined paper may be used as the dielectric, and this may be prepared by the person building the condenser. For this purpose a thin bond paper is most suitable. The sheets of paper should be a trifle larger than the sheets of tin-foil so that there will be a clear margin of about ½ in. around the edges of the tin-foil. A few more sheets of paper than tin-foil should be provided.

The paper should be carefully inspected for flaws, cracks and pin holes; these may be easily detected by holding each sheet of paper between the eye and a strong light. All defective sheets should be rejected. The selected sheets should then be dipped in a paraffin bath. Two plans may be followed in thus treating the paper. All the sheets may be laid in a flat dish such as is used in developing photographs, and some shavings of paraffin placed between each sheet with additional lumps of the substance on the top sheet. The dish may then be placed in a moderately warm oven, when the paraffin will melt and saturate the paper. If properly done the sheets of paper will be semi-transparent. This dish may then be removed and each sheet of paper lifted separately, so that any surplus paraffin may flow off. The paper should then be allowed to dry. Another, and better way so far as results are concerned, is to heat each sheet of paper so as to drive off the air and moisture and pass it through a bath of melted paraffin. The paper, which will rapidly absorb the paraffin, should then be drained of any surplus and dried.

Any one of three different methods of building the condenser may be adopted; but allowance must be made in the size of the tin-foil to suit the method. In the method illustrated by Fig. 2 the ends of the tin-foil are made to overlap the sheets of paper. Another method is to provide additional strips of tin-foil about an inch wide, for overlapping purposes, while a third method is to solder half of the number of sheets of tin-foil to a copper strip, and the other half to another copper strip, so that the two resemble books having leaves of tin-foil.

In assembling the condenser, two pieces of hard wood, preferably maple, and slightly larger in size than the paper sheets, are fitted with bolts as indicated in Fig. 1, and

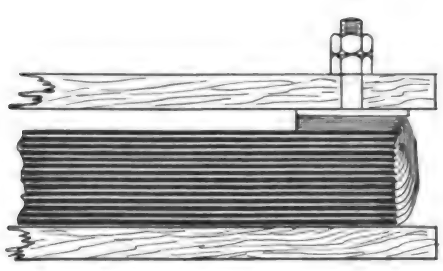

FIG. 2.—DETAIL VIEW OF CONDENSER.

the condenser is built up on the bottom piece. Two sheets of paraffined paper are laid on the wood, and in the center is placed a sheet of tin-foil overlapping to the right. Over this is placed a sheet of paraffined paper and then a sheet of tin-foil overlapping to the left. On this is placed another sheet of paper, then a sheet of tin-foil and so on, building up a pile of alternate sheets of paper and tin-foil; the latter projecting at the right and at the left alternately, until the last shee of tin-foil has been laid. On top of this are placed at least two sheets of paper and then the top part of the frame is applied and the nuts screwed down as tightly as possible.

The condenser should now be placed in a moderately heated oven, or better still on a sand bath over a Bunsen flame, care being exercised in the latter case to avoid overheating. As the paraffin melts, the bolts may be further tightened until all of the surplus paraffin is pressed out. The condenser should then be removed and allowed to cool.

When the paraffin becomes hard, the condenser may be unbolted and the projecting leaves of tin-foil bent up under the connecting bolt or binding post, as indicated in Fig. 2. This bolt should be headed with a flat piece of copper, the pressure of the corner bolts being sufficient to hold it in contact with the tin-foil leaves upon which it rests. After the top piece of wood is securely fastened, the condenser is ready for connection. One terminal should be connected to the break pillar, or mount, and the other terminal of the condenser to the break spring, or vibrator.

PRACTICAL NOTES ON BOILER FEEDING APPARATUS.

The Economizer.

BY CHARLES L. HUBBARD.

Economizers are commonly made up of vertical cast-iron pipes about 4 inches in diameter and 9 feet high, connected at top and bottom by headers. Each header is in turn connected with pipes running lengthwise, one at the top and one at the bottom, outside the brick chamber enclosing the apparatus. Each tube is provided with a geared scraper which travels up and down continuously for the purpose of removing the soot. A section of the Green economizer with its surrounding brickwork is shown in Fig. 1. The mechanism for operating the scrapers is seen at the top and may be driven by a belt from some convenient shaft or by an independent engine or motor. The feed water is forced into the economizer by the boiler feed pump at the lower branch nearest the point of exit of the gases and leaves through the upper branch pipe at the other end. The series of pipes and headers are enclosed in a brick chamber through which the furnace gases are caused to pass on their way to the chimney. The space below the lower headers is for the accumulation of soot removed by the scrapers. This soot must be removed at frequent intervals.

There are various ways of locating the economizer with relation to the boilers and chimney flue, depending upon the conditions to be met in each particular case. Dampers and flues should be provided so that the gases may be passed either through the economizer or turned directly into the chimney, in case it is desired to clean or

repair the economizer at any time. One disadvantage in the use of an apparatus of this kind comes from the fact that it reduces the draft of the chimney somewhat owing to the increased friction of the gases and also to their reduced temperature.

Provision must be made for this either by the use of mechanical draft or by providing a more powerful chimney than would otherwise be necessary. The percentage of saving by the use of an economizer will depend on circumstances, but can be determined approximately by the general formula given for feed-water heaters.

The average of nine tests reported by Mr. William R. Roney in a paper read before the American Society of Mechanical Engineers showed the rise in temperature of the feed water in passing through the economizer to be 140°, with a corresponding drop of 257° in the temperature of the furnace gases. The average saving in fuel for the same tests was 13.8 per cent. These results will of course vary somewhat in different cases. While economizers are commonly used for the purpose of reducing the cost of fuel, they are also installed in connection with existing boiler plants for increasing their capacity. The addition of an economizer is in effect adding to the heating surface of the boilers, although the additional surface cannot be rated on the same basis per square foot, owing to the reduced temperature of the gases to which

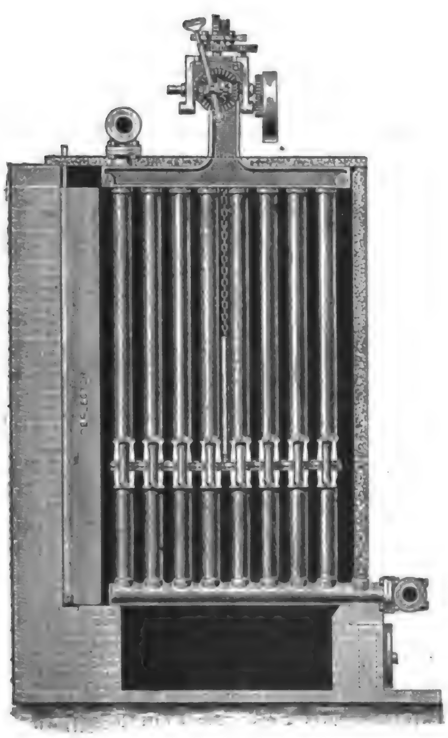

FIG. 1.—ECONOMIZER.

it is exposed. The percentage of saving in fuel by the use of an economizer may be taken as representing approximately, under average conditions, the increase in boiler capacity, should the same amount of fuel be burned as before the economizer was installed. It is customary under ordinary conditions to provide from 4½ to 5 square feet of heating surface in the economizer for each boiler horse-power.

METER TESTING EQUIPMENT.

BY R. L. ELLIS.

Some time ago the writer had occasion to design a testing arrangement for a company which had installed between 3000 and 4000 meters. On investigating the matter, he was struck very forcibly with the meagreness of detail of other boards obtainable, and this paucity of design leads him to believe that a description of the design as finally installed might prove interesting.

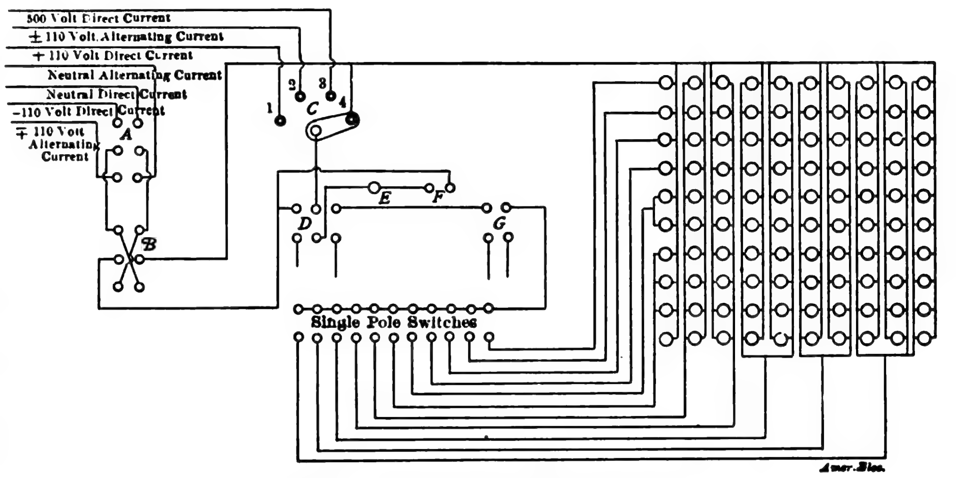

FIG. 1.—METER TESTING CONNECTIONS.

The problem was somewhat complicated owing to the fact that there were so many kinds of meters to test. There were 500-volt, 220-volt and 110-volt, direct-current meters; 220-volt and 110-volt, alternating-current meters; 220-volt, three-wire, direct-current meters, and 220-volt, three-wire, alternating-current meters, making in all seven distinct varieties.

The diagram of connections for the test board is given in Fig. 1. *A* is a double-pole, double-throw switch; *B* is a similar switch arranged as a pole-changing device; *C* is a single-pole, four-throw switch for connecting the potential leads to the meter; *D* is a triple-pole, single-throw switch with leads for connecting the test meter; *E* is a binding post for the potential connection to the meter; *F* is a similar connection for a voltmeter or the potential coil of a wattmeter, depending on which is being used; *G* is an ammeter connection, with double-pole, single-throw switch if desired. A line of single-pole switches is installed for connecting the load which is shown as a bank of lamps in the engraving. On the board as finally built the load consisted of a bank of lamps for non-inductive work, which was supplemented with motors and arc lamps when an inductive load was wanted. A feature of the board is the use of the same working voltage at the board regardless of the rated voltage of the meter under test; that is, the current going through the fields of the meter is at a potential of 110 volts always, regardless of the voltage across the potential coil of the meter.

The test of each of the different types of meter will be considered separately and the different switch positions given so as to make the operation clear. It should be borne in mind, however, that the two neutrals are grounded, as well as the negative of the 500-volt circuit, or are arranged so that they can be grounded when desired.

In testing a 110-volt, direct-current meter switch *A* is thrown up, switch *B* may be either up or down, and switch *C* is on contact No. 4. The test meter is connected at *D*, the potential coil being connected to one side of the field coil of the meter; the other side of the potential coil of the meter is connected at *E*, a voltmeter is connected at *F* and an ammeter at *G*.

In testing a 220-volt, direct-current meter, both switches *A* and *B* are thrown up, switch *C* is on contact No. 1, and the other connections are the same as when testing a 110-volt, direct-current meter.

In testing a 220-volt, three-wire, direct-current meter, the connections are the same as in testing a 110-volt, direct-current meter, with both fields in series. It should be noted, however, that this arrangement doubles the speed of the meter and consequently the constant.

In testing a 110-volt, alternating-current meter, switch *A* is down, switch *B* may be either up or down, and switch *C* is on contact No. 4. The other connections are the same as for testing a 110-volt, direct-current meter, with the exception that in alternating-current work with an inductive load a wattmeter is substituted in place of the ammeter and voltmeter.

In testing a 220-volt, alternating-current two-wire meter, switch *A* is down, switch *B* up and switch *C* is on contact No. 2. The other connections are the same as when testing a 110-volt, direct-current meter.

In testing a 220-volt, alternating-current, three-wire meter, the connections are the same as when testing a 110-volt, alternating-current meter with both fields in series. The constant is doubled in this case, as in that of the 220-volt, three-wire, direct-current meter.

In testing a 500-volt, direct-current meter, switch *A* is up, switch *B* down, switch *C* on contact No. 3, and the other connections are the same as when testing a 110-volt, direct-current meter.

While the board described may not have the best possible arrangement, it was most convenient for the particular conditions met with in the case under discussion.

THE KELLOGG COMMON-BATTERY TELEPHONE SYSTEM.

BY W. S. HENRY.

The telephone system installed in one of the Keystone Telephone Company's exchanges in Philadelphia by the Kellogg Switchboard & Supply Company is shown in the accompanying diagram. At the subscriber's station, when the receiver rests on the hook, the bell and condenser are in series across the two-line wires, and hence the bell can be rung by the ordinary alternating current used for ringing purposes. The receiver is short-circuited, and the transmitter, *T*, and an impedance or choke coil, *I*, are on open circuit. When the receiver is removed from the hook, the impedance coil and transmitter are connected in series across the two-line wires. In parallel with the impedance coil is a circuit containing the condenser and receiver. Current from the central office battery cannot flow through the receiver on account of the condenser in series with it, but it can readily flow through the impedance coil and transmitter, little or none of it passes 25 ohms, is designed to allow the transmitter to receive the requisite amount of current from the central office battery to properly operate it. The higher frequency voice current arriving from the line passes through the condenser, receiver and transmitter, little or none of it passes through the impedance coil, because it offers on account of its inductance, a much greater opposition to such a current than the condenser and receiver. Talking into the transmitter produces a rapid fluctuation in the strength of the battery current in the line circuit, thus affecting the distant telephone.

The exchange circuits operate as follows: When the receiver rests on the hook the condenser in the subscriber's instrument prevents the flow of battery current through the subscriber's telephone; but when the receiver is taken off the hook, sufficient current flows from battery $+B'$ through $g - g'$ $- T - I -$ line relay $LR - B'$ to cause LR to attract its armature, thus causing the line lamp, *L*, to light. The operator replies by inserting the answering plug, *AP*, in the proper jack and closing the listening key.

Current will flow from *B* through *g* — cut-off relay, *CO* — sleeve side of circuit —relay *SA* back to *B*, which causes the 500-ohm cut-off relay *CO* to attract its armature, thereby cutting out the line relay, *LR*, which in turn extinguishes the line lamp and also connects the two-line wires to the jack. Current can now flow and close both the supervisory relays, *SA* and *ST*, because the line circuit is closed at the subscriber's instrument. The closing of the relay, *ST*, opens the circuit through the answering supervisory lamp, *AL*, and thus prevents the lighting of the latter at this time. The operator can now communicate with the subscriber. The operator's receiver and a condenser are connected in series across the cord conductors, but there is also a condenser, *CC'*, in each cord conductor between the operator's head set and the subscriber's line circuit.

The operator proceeds to complete the connection by touching the tip of the calling plug, *CP*, to sleeve, *s*, of the jack belonging to the line wanted. If the line is busy, due to a plug being in a jack of that line at some other section, a click will be produced in the operator's receiver in the following manner: Current flowing from a battery through a 100-ohm relay — sleeve side of some cord circuit — sleeve, *s*, — tip, *t'* of calling plug — *a* — 5,000-ohm test relay, *R*, to ground, causes *R* to close its circuit, which short-circuits the impedance coil, *I''*, thus producing a sharp increase in the current through the primary, *p*, which causes a click in the operator's receiver. The operator then informs the waiting subscriber that the line called for is busy. If the line is not busy, *s*, as well as *t'* will be at the same potential as the ground; relay *LR* will not be affected and no click will be produced. If the line is not busy, the operator inserts the plug in the jack, which will operate the cut-off relay, *CO'*. She then opens her listening key and closes her ringing key.

Current now flows from *B'* through the ground — cut-off relay, *CO'* — sleeves, *s*, of jack and plug — resistance, *r*, back to battery, thus holding the cut-off relay closed while the ringing current flows from the generator through the tip side of the line—subscriber's bell and condenser—sleeve side of line—resistance, *r*—battery *B'*—ground to generator. When the ringing key is released, current flows from *B'* through ground—cut-off relay, *CO'*—sleeve, *s*, of jack and plug—relay, *SC*—back to battery,

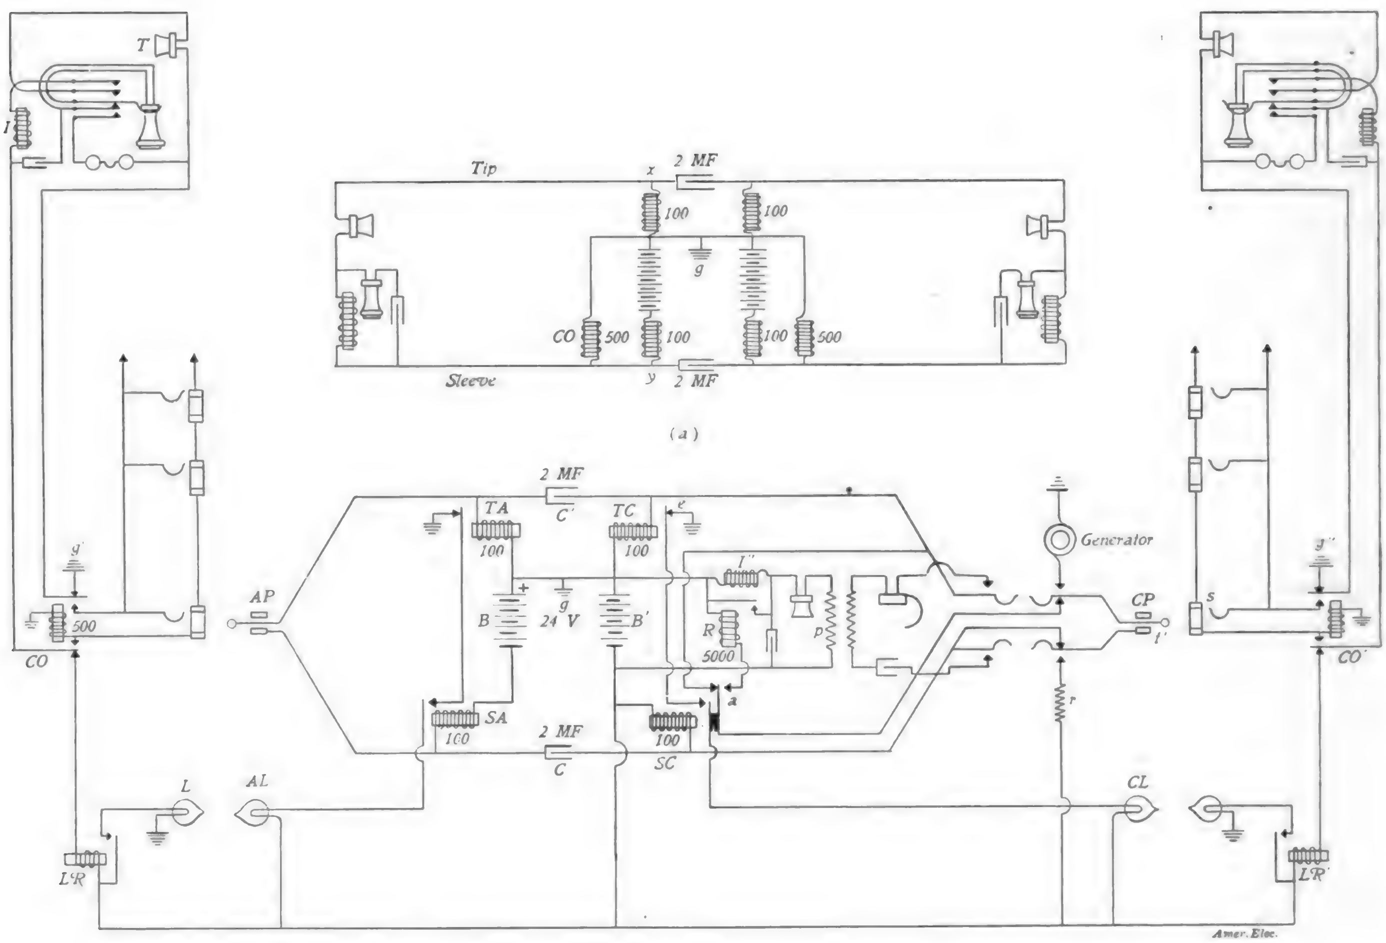

FIG. I.—KELLOGG COMMON-BATTERY TELEPHONE SYSTEM.

which keeps both relays, *CO'* and *SC*, closed. The closing of *SC* causes current to flow from *B'* through ground —*e*— calling supervisory lamp, *CL* (which it causes to light) to battery. The lamp, *CL*, will remain lighted until the subscriber called takes his receiver off the hook. Current can then flow from *B'* through relay, *TC*—*t'*—tip side of line—subscriber's transmitter and impedance coil—sleeve side of line—*s*—relay, *SC*—back to battery. This causes the relay *TC* to close, thus opening at *e* the circuit through the calling supervisory lamp, *CL*, which is an indication to the operator that the called subscriber has answered his telephone call. All three relays—*CO*, *SC*, *TC*—are now energized, and the condition of the circuit while the two subscribers are holding a conversation is shown at (*a*).

It will be seen from this diagram that each subscriber's circuit is supplied with current from a separate battery, there being a 100-ohm relay, which also acts as an impedance coil, between each terminal of each battery and the line wires. The battery and one of these relays on each side of the cord circuit are shunted by a 500-ohm cut-off relay whose resistance is sufficiently high not to deprive the line circuit of all the current necessary for the operation of the transmitters, and yet not too high to cause this 100-ohm relay to open when the receiver rests on the hook switch.

As stated, each subscriber's transmitter receives current from a separate battery through two inductive resistances, that is,

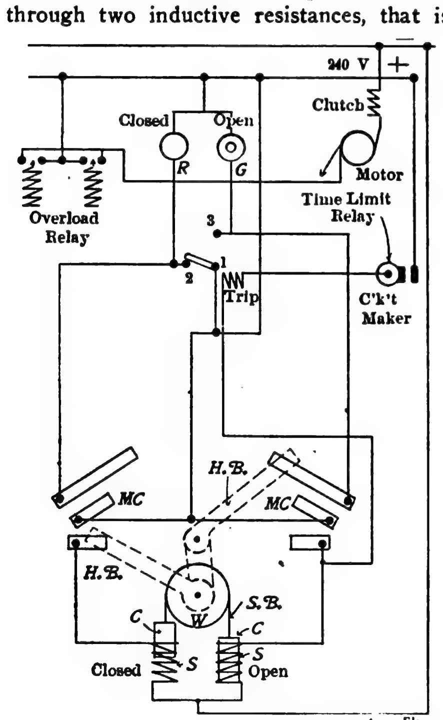

FIG. 3.—CONNECTIONS FOR STANLEY-G. I. SWITCH.

relays. A fluctuation of current in the original subscriber's circuit produces a similar fluctuating difference of potential between points, *x y*, which will produce a fluctuating charge upon the two condensers, *C C* which will, in turn, produce a fluctuating flow of current through the called subscriber's circuit.

When the subscribers hang up their receivers, the supervisory relays, *TA* and *TC*, are deprived of current and hence release their armatures, which cause the supervisory lamps, *AL* and *CL*, to light, thus notifying the operator that she should pull out the plugs, which restores the circuit to its normal condition.

HIGH-TENSION, CIRCUIT-BREAKING DEVICES.

BY W. T. FERNANDEZ.

The improved type "H" high-tension oil switch is quicker in action and more reliable than the type "H" switches previously described. The mechanical features have been improved so as to eliminate the possibility of "pumping" and by rendering

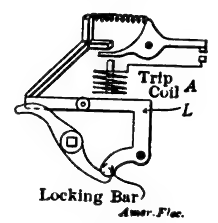

FIG. 1.

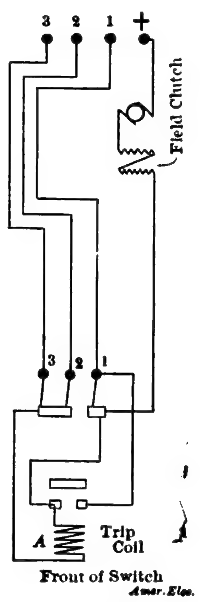

FIG. 2.

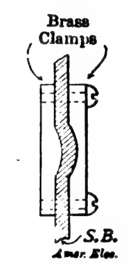

FIG. 4.

the mechanism more rapid in its action, prevent to some extent the formation of explosive gases in the oil pots when the switch is opened under load or short-circuit conditions. The added improvements are illustrated in Fig. 1. *A* is a solenoid which releases the locking device, *L*, and permits the driving mechanism to operate when the operating current is applied, as follows: When the control switch is thrown in, the motor, clutch coil and locking solenoid *A* are energized at the same instant, with the result that the locking device is released and the motor drives the switch home; the mechanism is then locked and cannot return to its first position until the control switch has been thrown in that direction. The diagram of control connections for the type "H-3" switch is the same as for the other types of "H" switches, but the frame wiring is different and is illustrated in Fig. 2. As the crank shaft is locked when it arrives at either the open or closed position, cam adjustment is unnecessary and the only attention the switch requires is oiling at regular intervals in addition to regular cleaning.

The control connections of the solenoid type of main-line switch manufactured by the Stanley-G. I. Electric Manufacturing Company are illustrated in Fig. 3. The driving power is furnished by the solenoids *SS* and taken up by dash-pots at the end of the switch's travel.

It will be seen that the soft-iron cores, *C*, which are attached to the steel band, *SB*, which is in turn attached to the crank wheel, *W*, may move freely in the solenoids and thus turn the crank shaft through an angle of 180 degrees, resulting in throwing the circuit contacts either into or out of the oil-pot contacts.

The headboard switches, *HB*, correspond to the movable fingers of the G. E. type "H" switch and are actuated by the crank shaft, so that the operating circuit is automatically shifted from the coil last used to the coil to be used in the next operation of the switch.

It will be found with this type of switch that the automatic switch, *HB*, will sometimes stick, thus causing the oil switch to pump. This condition may be brought about by several causes; the contact clips may be too tight, the headboard may be out of line, or the dash-pots may be defective in operation. The "pumping" effect may be eliminated to a great extent by disconnecting the master clips, *MC*, but the cause of the trouble should always be located and repaired before the switch is again put in service. If the clips are too tight they should be spread apart; the headboard should be lined up and the dash-pots examined. The rawhide washers may sometimes become dry and bind on the sides of the pots, or if the switches are located where there is considerable variation in temperature, the washers will become stiff in cold weather and bind on the sides of the pots, seriously affecting the operation of the switch. It will be found advisable to remove the washers and rub them well with graphite; this will result in reliable operation.

The automatic switch should be lubricated with vaseline at regular intervals, so that it will not bind on the contact clips. Another cause of trouble is the breaking of the steel bands, SB, at the point where they are riveted around the pin of the cores. This trouble may be obviated by substituting for the rivets the style of clamp shown in Fig. 4. The solenoid coils are wound for a momentary application of current, so that failure of the automatic switch to operate promptly will cause these coils to heat up and eventually to burn out. The control switch lights indicate when the automatic switch sticks, for if the control switch is thrown into the "close" or "open" position and the signal lights indicate an opposite position, it is evident that the automatic switch is sticking and requires immediate attention to prevent the burning out of the solenoids. The moving parts should be oiled at regular intervals and the mechanism of the switch kept absolutely clean, to insure effective operation.

In addition to the above described types of main line switches, there is used for individual machines, and in some cases, small feeders, a type "K" hand and solenoid-operated switch, as illustrated in Fig. 5. It must be remembered that whereas the

G. E. and Stanley-G. I. main-line switches have a total break of twenty-eight inches in oil, the type "K" has a break of but eight inches, and is, therefore, limited in its capacity to about 600 amperes under short-circuit conditions, and should be equipped with a limit relay in addition to the regular time-limit device as mentioned in a former article.

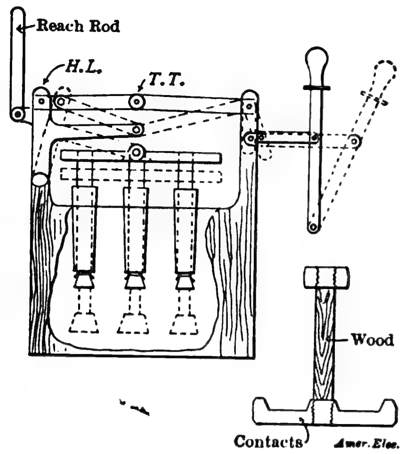

FIG. 5

Fig. 5 illustrates the mechanism of the type "K" switch, in which the toggle joint, *TT*, is operated by the lever, *HL*, or by the mechanism shown in Fig. 7 (G. E.) and in Fig. 8 (Anderson). Both mechanisms are of the solenoid type and consist of a "close" and "open" coil, actuated by direct current from a control switch similar to that used with the main-line switches.

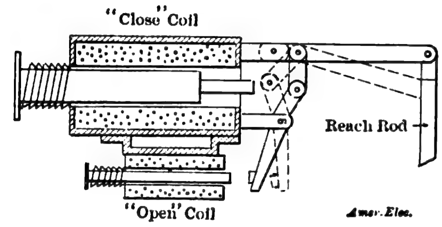

FIG. 7.

On the switch mechanism the principal parts to be watched are the bolts holding the toggle mechanism together, as this type of switch opens by gravity and not by a power drive as in the main-line types.

Where the solenoid mechanisms are used, the adjustment of the reach rod, which extends from the mechanism to the switch proper, should be marked after it has been properly adjusted, and inspected at regular intervals thereafter so that any slacking of that rod may be promptly noted and repaired. As a precautionary measure, the oil should be changed in all switch compartments once every year, and immediately after a switch has been opened under a short-circuit, as the oil will be found to be greatly carbonized and unreliable for future use.

The oil removed from the pots once a year may be filtered through a felt filter and used again, but all oil taken from switches which have opened under short-circuit conditions should be discarded at once, as the retention of it in a switch will invite an explosion if the same switch should open a second time under short-circuit conditions.

Oil-switch mechanisms should not be tinkered with by the entire station force; they are accurate mechanisms and require the attention of a mechanic who knows what he is doing. Promiscuous experimenting with them may result in one of three things —an injured man, a feeder thrown off under load, or a "pumping" switch which will damage both itself and the machine attached to it.

NOTES ON WATER COLUMNS.

BY W. H. WAKEMAN.

The principal reasons for the extensive use of water columns on tubular boilers and others which might be operated by separate gauge cocks, is that not so many holes in the heads are required, and because a water column may be located in any convenient and near-by place, whereas gauge cocks must be on the boiler front.

Under the old plan of separate connections, where three cocks and a water glass were used, it required five holes in the boiler, but a water column calls for only two holes, even if four cocks are used. The natural consequence is that the two holes are made larger in diameter, although not necessarily so. One advantage of larger holes and connections is that they are not so easily choked with sediment and scale. A possible disadvantage of water columns in general is found in the fact that if the lower connection does become filled with sediment, it prevents the use of both cocks and water glass; but owing to the location of the upper connection above the water line there is little danger of this obtaining.

As these connections are usually made of 1¼-inch pipe it requires considerable sediment to entirely fill them, but as some men seem to think that it is seldom necessary to blow them out, it is a wonder they do not become useless. A competent engineer will have this important matter attended to every day. Whether this entails trouble or not will depend on the care with which the drip pipes were located. If a ¾-inch nipple were screwed into the settling chamber of the column, followed by a valve and a short nipple, muddy water will be blown out on the floor every time an effort is made to secure free circulation through the pipes.

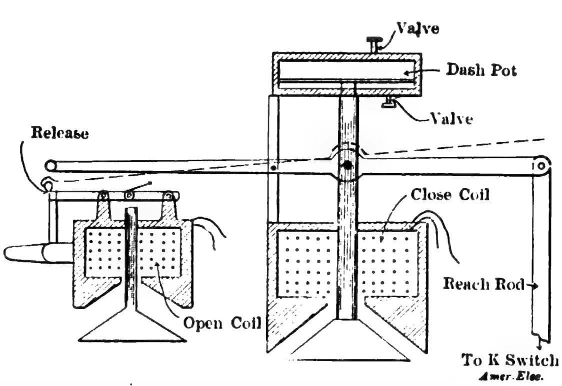

FIG. 8.

In some cases the drip pipe is continued into the ash pit, consequently when the valve is opened light ashes are blown out into the room and in rising cover the boiler front, entailing some labor in cleaning it. In either of the above-mentioned cases the natural tendency is either not to open the drip valve, except at long intervals, or to shut it quickly whenever it is opened.

Water and sediment may do no harm on the boiler room floor, and a boiler front covered with ashes will not prevent the boiler from evaporating water, but engineers and firemen seldom relish such a state of affairs, although some of them had rather endure the dust and dirt than spend the time necessary to remove them.

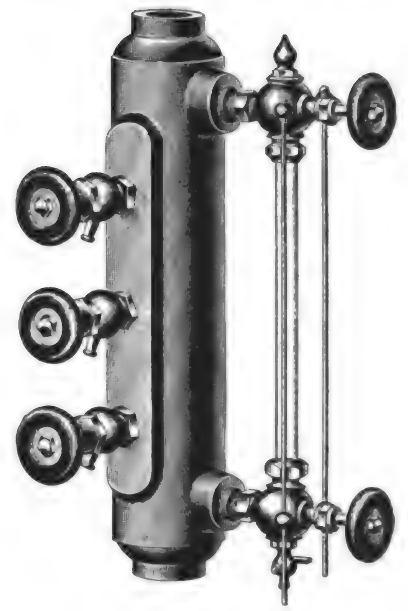

FIG. 1.—WATER COLUMN.

It is much better to remove the cause, or what is still better, never let it come into existence. This can be accomplished by continuing the drip pipe down to and underneath the floor, then carrying the discharge pipe to the sewer, or to a cesspool made for the purpose, if a sewer is not available. Under these conditions there is absolutely no excuse for allowing these connections to become choked with sediment, and there is no real good excuse for it under any other conditions.

In a certain boiler room there are five of these columns connected in this way, and they are always in good order, causing no trouble whatever. Of course all of the drip pipes are connected into one common discharge pipe to the sewer, but no other pipe is connected into it.

At night the valves in both upper and lower connections are closed while the drips are left open. If an attempt is made the next morning to blow out the lower connection to No. 1 column without shutting the drip valves on the others, muddy water is blown up into the other columns, but this is easily prevented by first closing all of these drip valves except No. 1 and then opening each in turn when it is wanted.

Brass pipe is extensively used for connecting water columns, but it is not approved by all boiler inspectors, as it sometimes fails under pressure. When subjected to changes in temperature it expands and contracts more than the iron and steel heads or shells into which it is fitted, hence leaky joints result, and this always means corrosion that weakens the metal until it is no longer safe under high pressures.

Extra heavy iron pipe is recommended by these inspectors, and their advice is usually worthy of adoption. They examine boilers operated under a great variety of conditions, and are, therefore, competent to advise in such matters.

All threaded joints in such work should be fitted so that nearly all of the threads will be covered; for where several are exposed to view it generally denotes a weak joint. Where connection is made into a boiler head about one-half inch thick, all threads on a 1¼-in. pipe cannot hold in the metal as it is not thick enough, but the surplus should appear on the inside, for if the pipe is only flush here, several must be exposed to view on the outside, and this is not the best kind of joint, because a pipe is weak where a thread is cut on it, therefore it should be well screwed into the head. The same reasoning applies to the top connection into the shell.

Brass unions with ground joints are frequently used on these pipes, but observation of many plants shows that these unions leak just enough to cause corrosion where it is least expected. On one battery of boilers the writer removed these unions, which were put in when the plant was installed, and the change made a great improvement. The column was made in two pieces and bolted together, hence it was equal to a flange union. These have needed repairs but once in more than ten years, which is fortunate because the absence of unions makes it more difficult to remove them.

On another battery the unions were retained because iron columns for supporting the floors above were near the boiler fronts, making it inconvenient to remove and replace bolts and nuts. As these have needed repairs on several occasions the unions were useful.

An angle valve in the top connection and a cross valve in the lower connection make it possible to remove the bonnets when cleaning boilers, thus securing a straight passage into the connecting pipes for removing any scale that may have collected at these points. The nozzle of a hose may be inserted, and when water is turned on the pipes are quickly cleaned.

Water columns may be divided into two classes: those without extra fixtures, and those which are fitted with high and low-water alarms. Many engineers do not object to these latter water columns when new boilers are installed, but later one oftentimes finds that if the water level should fall to the center of the shells or rise to the top of them, no warning whistle would be heard, and this state of affairs denotes the worst kind of opposition. The whistle with which each water column was originally provided had been removed and a cap put on in its place. If one should inquire concerning the cause of such action the reply is usually that it was always blowing and the engineer was tired of hearing it. When this appliance is properly installed and kept in repair, the whistle never blows except when there is good reason for it, and its removal is a clear indication that affairs are not properly managed. Very few men are willing to admit that the water level ever gets low enough to injure the boiler, or high enough to wreck the engine, yet some of them will not permit an appliance to be used that will blow a whistle when the danger line is approached.

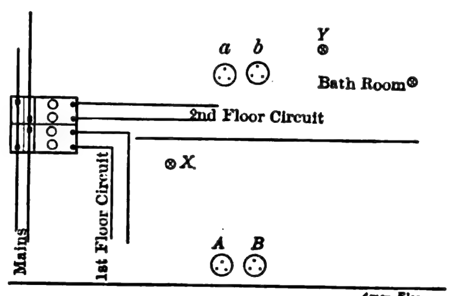
The worst fault that the writer has found with these columns and fixtures is that one or both of the floats become partly filled with water and fail to operate. If it is the upper one it will not sound an alarm when too much water is pumped in, and if it is the lower it causes the whistle to blow continually. The remedy is to have extra floats on hand so as to replace a defective one without delay.

Letters on Practical Subjects

Communications intended for publication in this department must be received at this office not later than the 15th of the month prior to the date of publication.

Problem in House Wiring.

An old house had been wired for electric lights and the floors replaced and carpets



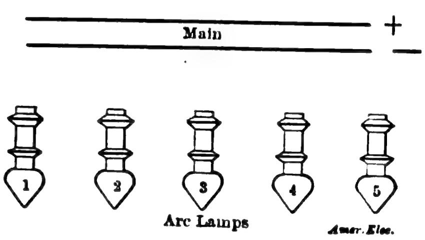
PROBLEM IN HOUSE WIRING.

laid before the lighting service was connected. When the current was turned on the light in the first floor hall and the light in the second floor hall, both of which were controlled by a pair of three-way switches, refused to light properly. With the switches in a certain position all the lights would burn at their full candle-power. Turning switch *A* extinguished light *X*, turning switch *B* extinguished lamp *Y*; turning switch, *A*, lighted lamp, *X*, and a lamp in the second floor bath room in series; turning switch, *B*, caused the lights, *X*, *Y*, and the bath room light to merely burn dimly. Two circuits were provided, one for the first floor and one for the second floor. I searched for a long while to locate the trouble, and am interested to know whether any of your readers can surmise what the trouble was.

Scranton, Pa. H. F. Hartman.

Problem in Arc Lamp Wiring.

I submit the following problem in arc lamp wiring to your readers for their consideration. Five series arc lamps requiring 35 volts each, are to be connected to a 105-volt circuit so that three will be burn-



PROBLEM IN ARC LAMP WIRING.

ing at one time, the center lamp being connected to each group, or in other words, it is required to connect lamp No. 3 so that it will burn with either lamps Nos. 1 and 2, or with lamps Nos. 4 and 5.

Paterson, N. J. M. Simon.

Mr. Riggs' Problem in Telephone Signalling.

It was discovered, but unfortunately too late to be rectified, that the first two solutions published last month to Mr. Riggs' problem are inadmissible. With the connections as shown the bells would ring continuously, and with the batteries connected in opposition the bells could not be made to ring at all. The other solutions are correct.—Editor.

The Hayes Telephone System.

Referring to the correspondence published some months ago on the Hayes telephone system, I would like to add the following additional remarks. As was pointed out before, the operator's telephone set is practically the same as a subscriber's telephone circuit, and is affected the same by separating from it the condenser, which is wired in shunt to the transmitter and coil. While the condenser keeps the line free from leakage or shunts, it more than assists in transmission. The condenser gives the side tone so necessary for long-distance transmission, in common battery operation. When subscribers object to this side tone (increased sometimes owing to

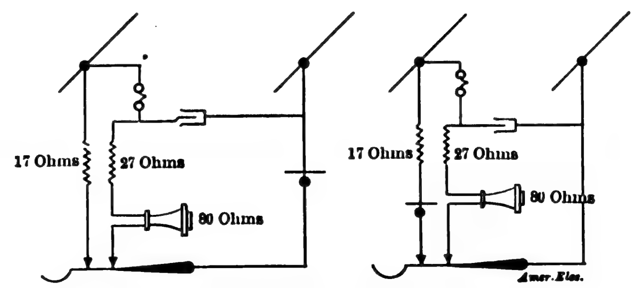


FIG. 1.—HAYES TELEPHONE SYSTEM.—FIG. 2.

the nearness of the instrument to the central office whereby it receives an abnormal supply of current) relief is given by changing the position of the transmitter, thus eliminating the condenser effect. The transmitter being in series with the line the current does not fluctuate with the vibrations of the transmitter. The repeating coils in the office, the cable, etc., all act to retard, and there is a drag to the transmission which impairs the effectiveness of long-distance work. With the condenser in circuit, energy is stored up which induces an alternating current in the 17-ohm winding and thus in the line. This current being of low amperage, is not retarded to the same extent. Fig. 1 shows the regular connections and Fig. 2 shows the connections without the side tone.

Philadelphia, Pa. W. A. Loveland.

Alternating Current Power Measurement.

I enclose a wiring diagram for the solution of the problem in alternating-current power measurement which was inserted in the August number of the American Electrician. Of the several answers published in the October number, none, in my opinion, is correct. One answer attempted to give a method to obviate the difficulty of using three meters. The problem, however, was to use three meters. This method has been used here with success, and in one case there is a polyphase meter on the same circuit with the three separate meters and the two registrations are almost identical. Referring to Fig. 1:

$E'' = \sqrt{3}\, E' \div 20$, where ratio of power transformer is 20 to 1.

$I'' = I' \div k$, where k is the ratio of the current transformer.

$W = I' E' \sqrt{3}$, or the total power of the three-phase circuit.

$W' = I' E' \div \sqrt{3}$, the power to be measured by one meter.

$W''' = I'' E''$, or the actual power measured in one meter.

$$\frac{W'}{W'''} = \frac{I' E'}{I'' E'' \sqrt{3}} = \frac{20\ k}{3},$$ constant of the meter.

The working diagram of connections is shown in Fig. 2.

Oakland, Cal. S. J. Lisberger.

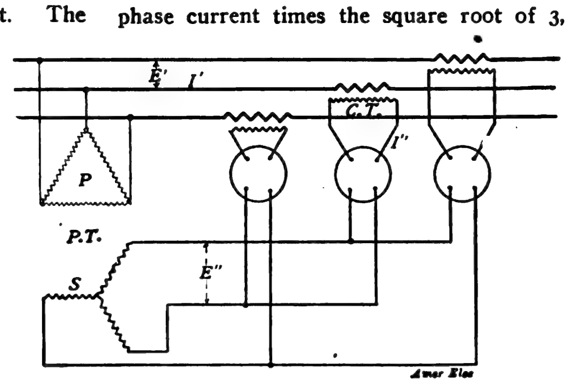

FIG. 1.—MR. LISBERGER'S SOLUTION.

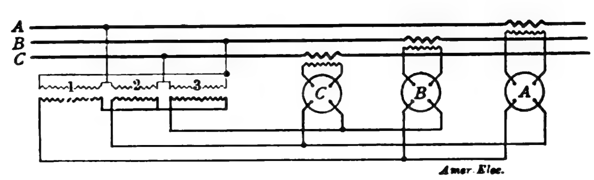

FIG. 2.—MR. LISBERGER'S WORKING DIAGRAM.

Mr. Munson's solution to Mr. Lisberger's problem published last month contains an error in the development of the meter constant. In his solution the current transformers each receive the resultant of the phase current times the square root of 3, or 1.732. The constant, 1600, should be divided by $\sqrt{3}$ in order to obtain the correct power, and this constant would be the same as that given in Mr. Umstead's solution, a very unwieldy figure. In order to get an even constant, the meters should be connected as shown in Fig. 3 herewith. The primary coils of the potential transformers are connected in star. Each coil would therefore receive $2{,}300 \div \sqrt{3}$, or 1,330 volts. Each wattmeter would then receive 133 volts and the constant would be 160×10, or 1,600. The sum of the reading times 1,600 would give the power in the system.

York, Pa. Carl E. Freeman.

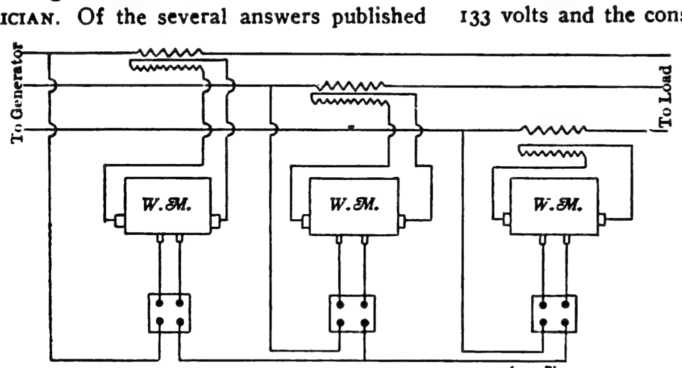

FIG. 3.—MR. FREEMAN'S SOLUTION.

[Of the various solutions offered, only one—Mr. Freeman's—complies fully with the requirements, although Mr. Sweetnam's solution published last month shows a correct method for measuring the power with two, instead of with three wattmeters. The several writers, including Mr. Freeman in his discussion of the solutions offered by Mr. Munson and Mr. Umstead, have failed to recognize the fact that if the current in the series coil is I, and the electromotive force across the shunt coil is E, the reading of the wattmeter need not always be IE. Even when the load is non-inductive, in the solutions suggested by Mr. Munson and by Mr. Umstead the current in each meter would be electrically displaced from the e.m.f. of the potential coil by 30°, or a constant of $\cos 30° = .866$ would have to be introduced. Since $\cos\,(30° + \theta)$ is not always equal to $.866 \cos \theta$, it is impossible to assign a "constant" for the connections suggested when the power-factor of the load ($\cos \theta$) is variable. In other words, the solutions given by Mr. Munson and Mr. Umstead are fundamentally incorrect.—Editor.]

Telegraphing With Open Circuit Batteries.

I note in the October number a scheme for telegraphing with dry cells or any open circuit battery. Enclosed is a sketch, Fig. 1, of another scheme which dispenses with the three-way switch, and only requires one wire, if a good return is used. Referring to Fig. 2 it will be noticed that a back contact for the key is used, and this is insulated from the frame. The circuit closing switch should be removed from the keys. If the same number of cells are used at each end and are connected so that when both keys are depressed they will oppose each other, one station can "break" the other by depressing the key. The back contact for the key can be had by shaping a piece of tin 1 in. by ½ in., as shown at R in Fig. 2, and fastening this to the table by means of a screw. It will be necessary to put a small piece of paper between this back contact and the frame of the key.

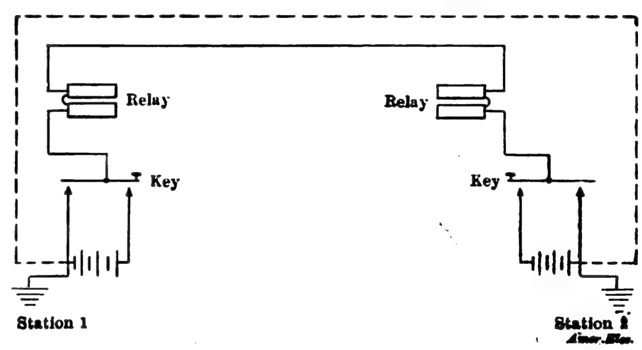

FIG. 1.—TELEGRAPHING WITH OPEN-CIRCUIT BATTERIES.

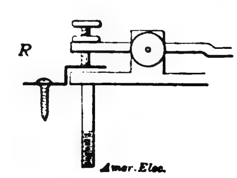

FIG. 2.—BACK CONTACT.

Paris, Texas. M. D. Hockler.

When I came across Mr. Jackson's method of telegraphing with open circuit batteries published in the October number, it brought to mind a piece of apparatus which I once made use of to obtain the same results. The difference between my method and Mr. Jackson's, is that in his, the connections are similar to those used in intercommunicating telephone systems and require an extra line wire for each station; whereas in mine, use is made of the ordinary connection of the instruments on one line. Regular telegraph instruments are used and the key is changed, as shown in Fig. 3. A piece of brass insulated from the base is placed under the regulating thumb screw

at the back end of the lever. The general connections of the instruments and line are given in Fig. 3 and Fig. 4 shows how they are connected when mounted on a wooden base. A serious drawback to this arrangement is that each station has to depend upon its own battery to supply the current for all of the instruments on the line.

Tallahassee, Fla. H. S. WHITE.

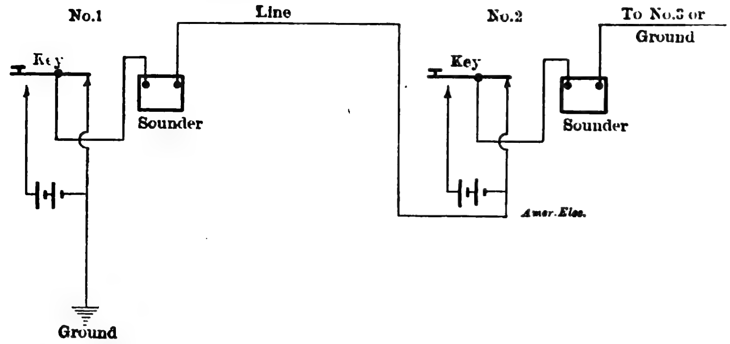

FIG. 3.—TELEGRAPHING WITH OPEN-CIRCUIT BATTERIES.

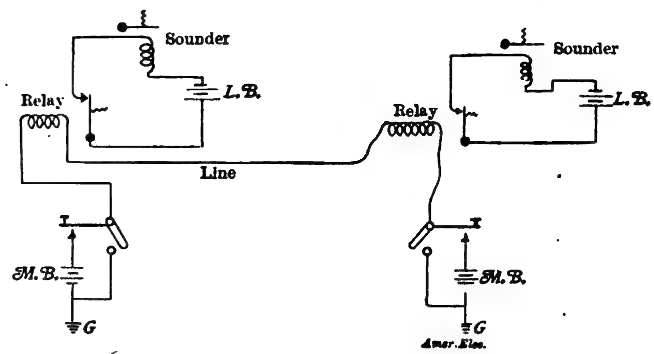

FIG. 6.—TELEGRAPHING WITH OPEN-CIRCUIT BATTERIES.

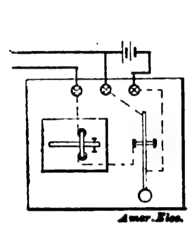

FIG. 4.

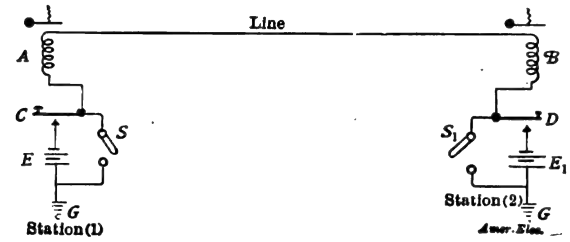

FIG. 5.—TELEGRAPHING WITH OPEN-CIRCUIT BATTERIES.

Seeing Mr. R. C. Jackson's letter in the October number on telegraphing with open circuit batteries, I beg to offer the enclosed solutions which I think are better and more practical, especially for lines of any great length. Fig. 5 shows an arrangement consisting of two sounders, A and B, keys C and D, switches S and S_1 batteries E and E_1 one line wire and two ground connections for use on short lines. When the line is not in use, switches S and S are closed, grounding the line at both ends. When Station I desires to signal Station II, the switch S is opened, thus clearing that end of the line. When the key, C, is depressed, current flows from the battery E through key C, sounder A, line sounder B, switch S to ground G and back to battery E. Fig. 6 shows the same system equipped with relays and local batteries.

San Francisco, Cal. J. J. MARSHALL.

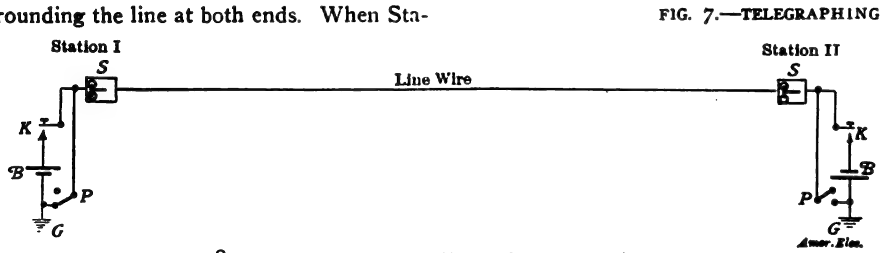

FIG. 8.—TELEGRAPHING WITH OPEN-CIRCUIT BATTERIES.

Enclosed is a diagram (Fig. 7) of a method for telegraphing with open circuit batteries, which is in some respects similar to the method published in the October number of the AMERICAN ELECTRICIAN. The scheme may be used for any number of stations; but each station must have a battery of sufficient strength to work the line. The operator wishing to use the line, moves the three-pole switch so as to put his battery on the line. The line may then be used as an ordinary closed circuit line, the operator throwing his switch back again when finished. I have used this scheme on a three-station line for several months and find it very satisfactory, the expense for battery being slight.

Glen Ellen, Cal. P. M. QUIEN.

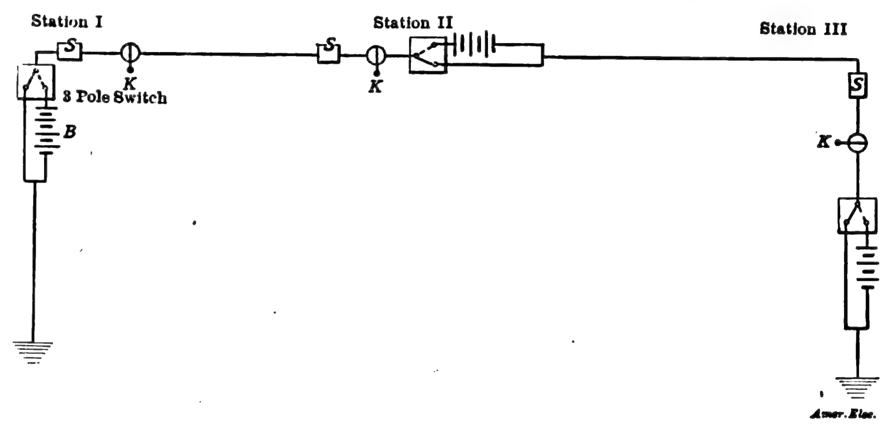

FIG. 7.—TELEGRAPHING WITH OPEN-CIRCUIT BATTERIES.

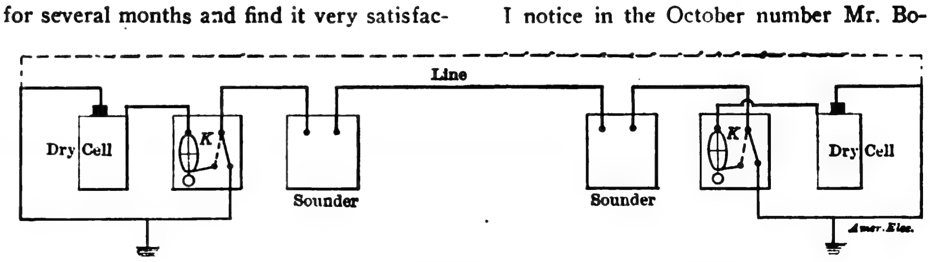

FIG. 9.—TELEGRAPHING WITH OPEN-CIRCUIT BATTERIES.

Fig. 8 herewith shows a method of using dry cells for short-line telegraphy. Only one line wire is used. An ordinary telegraph key may be used, and by insulating the spring switch contact from the post on which it is mounted and connecting it to ground, the two-way switches shown may be dispensed with. The operation of the switch and key are then the same as when operating on a closed-circuit line. In the diagram, S is a sounder, K a key, and P a two-way switch.

Reno, Nev. L. D. STOVER.

I was interested in Mr. Jackson's sketch in the October number, and enclose a sketch, Fig. 9, for telegraphing with open circuit batteries using one line and the ground. The regular switch is removed from the telegraph key and a three-way switch mounted on the same base with the key, using it in the same manner as a regular switch. Similar poles of the battery are connected to ground.

Waxahachie, Texas. W. J. FUSTON.

Continuous Ringing Alarm Bell.

I notice in the October number Mr. Boquet's inquiry about a continuous ringing alarm bell. I would suggest in reply to his inquiry that he fit two swinging hammers on the shaft of his ¾-h.p. motor and fasten the motor close to the bell so that

the hammers can strike it. The weight of the hammers will depend on the starting torque of the motor; but a little experimentation will suffice to ascertain this, care being taken not to choose too heavy a weight as this might under the action of the motor crack the bell. I believe with this arrangement he will be able to awaken the heaviest sleeper in his town. The motor may be started from any convenient place, provided it is a self-starter. Reducing gear might also be introduced if it is advisable to use heavy hammers.

Electric, Mont. J. M. Schmidt.

Mr. Mahaffey's Problem in Lamp Installation.

Enclosed find a solution of Mr. Mahaffey's problem in incandescent lamp wiring published in the October number. The diagram, I think, explains itself, each lamp

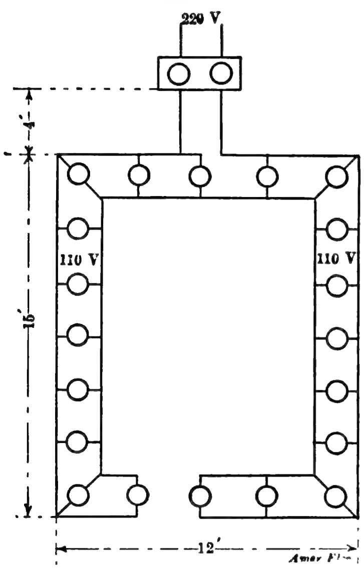

FIG. 2.—MR. BULLARD'S SOLUTION.

receiving 110 volts. The total length of wire from the fuses is approximately 146 feet.

Boonton, N. J. N. E. Weekes.

Enclosed herewith is a solution to Mr. Mahaffey's problem in lamp installation. The potential of the feed wires being 220

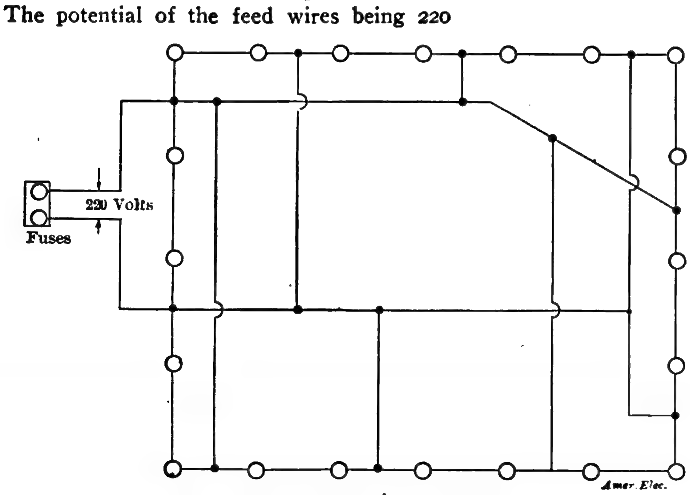

FIG. 1.—MR. WEEKES' SOLUTION.

volts and the potential of the lamps 110 volts, I have employed the three-wire system, which would require only about 107 feet of wire.

Schenectady, N. Y. J. E. Bullard.

Similar solutions were received from J. S. Gibbs of Dallas, Texas, and W. C. Wight, of Portland, Ore.

I send herewith a wiring diagram for Mr. Mahaffey's problem published in the October number. Ten lamps are placed in multiple on one side of the circuit and ten on the other side; the neutrals are then

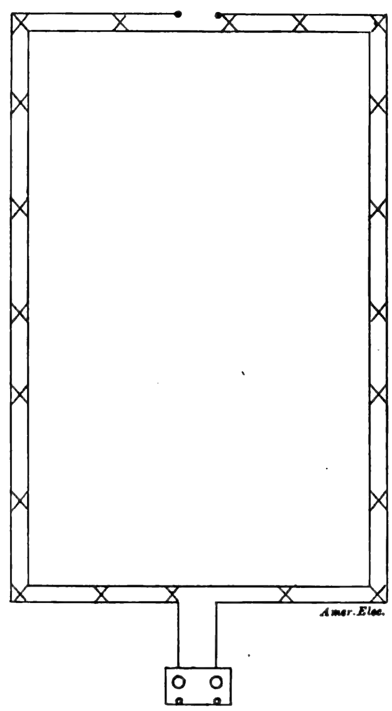

FIG. 3.—MR. MARSHALL'S SOLUTION.

connected together, thus placing the two banks of lamps in series. If one or a number of lamps burn out on one side, the voltage on that side will increase to such an extent as to affect the life of the remaining lamps; but if the lamps were placed two in series across the line a fault in one would throw out the other, or the extinguishing of one would necessarily mean the extinguishing of the other.

San Francisco, Cal. J. J. Marshall.

Mr. Marshall's solution is similar to Mr. Mahaffey's solution of his own problem.

Mr. Mahaffey's problem in lamp connections published last month may be readily solved as indicated in Fig. 4 herewith. Two lamps are placed in series across the 220-volt mains, thereby necessitating a minimum amount of wire.

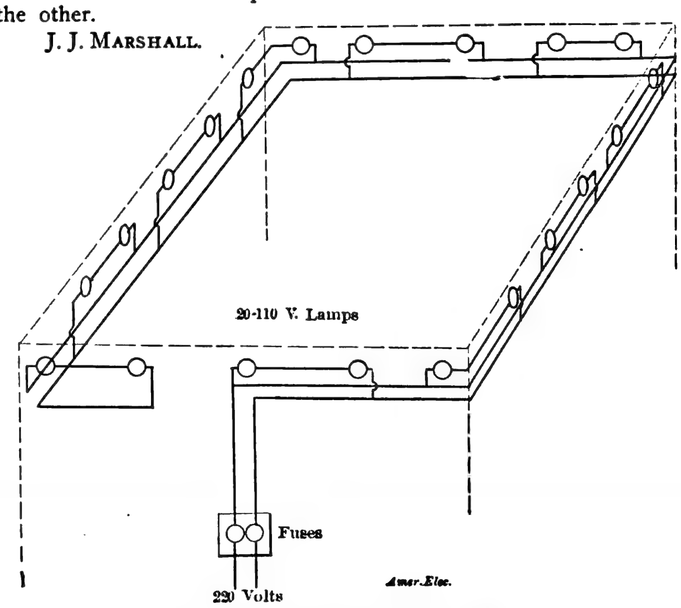

FIG. 4.—MR. ROBINSON'S SOLUTION.

Detroit, Mich. W. P. Robinson.

A similar solution was also received from W. A. McCown, of Ladonia, Texas.

Enclosed herewith is a solution of Mr. Mahaffey's problem in wiring, which was published in the October number. The diagram is so plain and the connections so simple that further comment is unnecessary.

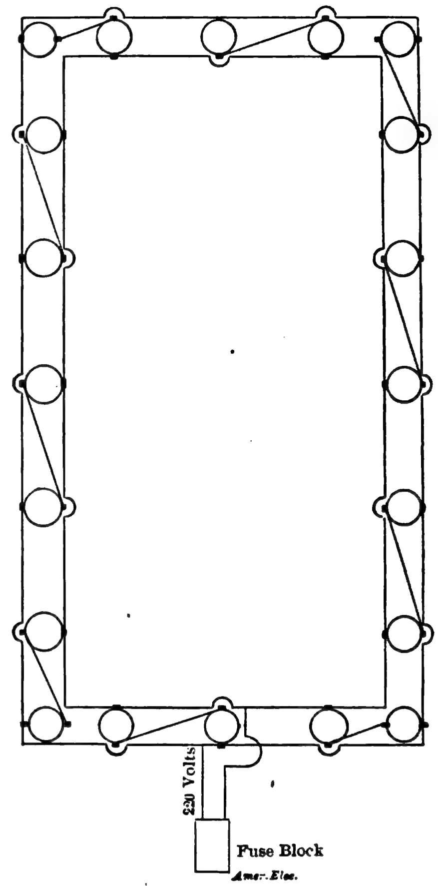

FIG. 5.—SWAFFIELD'S SOLUTION.

Elkhart, Ind. R. Swaffield.

A similar solution was received from H. S. White.

Questions and Answers

Inquiries not accompanied by the name and address of the inquirer, will not receive attention.

How can the current in a three-phase circuit be measured by a single ammeter? R. P. F.

This can only be done if the three phases are balanced. The current would then be equal to that indicated by the ammeter times 1.732.

What substance should I add to feed water in order to guard against scale in the boilers? C. E. W.

This can only be determined by chemical analysis. Unless you are a chemist it would not be wise for you to undertake to doctor the feed water.

When connecting a shunt-wound motor to a railway circuit, should the ground connection be brought directly to the motor, or should it pass to the starting box? W. P. H.

It is better practice to connect the motor to ground, since this affords better protection to the armature of the machine.

Can lead-covered cables be used for transmitting high-tension current? C. M.

Yes; but the use of lead covered cables should be avoided unless absolutely necessary. Wherever possible, high-tension wires should be run in open sight and be rigidly supported upon insulators of good design.

What substance should be used to insulate the secondary wires of a high-potential transformer? In "Electrical Designs" one is told to wind the coils on a form and then tape and bake. What insulation should be used between layers of these coils? S. F.

Fill the transformer casing with paraffine oil.

Why is not mercury more commonly used for switches? (2) What is the best kind of oil for an oil-break switch? A. B.

The reason mercury is not used is because it forms an amalgam with most metals, so that it will leak out of a metallic receptacle. (2) Fusal oil.

How can I protect an iron pipe from the deleterious effect of salt water? We use salt water for condensing purposes, and an iron pipe is used for an intake; but this rusts and is eaten away. T. W.

Iron pipe dipped in liquid asphaltum, rather than coal tar and pitch is said to afford the best protection.

I have some instruments finished in bright brass and wish to know if the brass can be easily oxidized or made black? G. O.

A mixture generally employed for the production of a black or oxidized finish on brass consists of a solution of carbonate of copper in ammonia. The brass is immersed in this solution and allowed to remain until the desired tint is obtained.

Why do alternating-current fan motors take so much more current than direct-current fan motors? H. T.

Small alternating current motors are less efficient than small direct current motors since the former do not operate at unity power factor and require in addition shading coils for starting which are always in circuit and thereby entail a continuous loss.

In transforming three-phase currents, can two transformers be used in place of three? B. B.

Two transformers may be used provided the primary terminals are connected to the three line wires exactly as two incandescent lamps would be connected to the wires of an ordinary three-wire system, and the secondary wiring similarly connected to the three secondary wires.

We have a compound-wound dynamo, and the brushes have to be shifted every time the load varies to any extent, and as the load increases the voltage drops. How can this trouble be remedied? N. C.

The reason the voltage of your machine drops as the load increases is because the series winding is wrongly connected. If you will reverse this your troubles will probably be at an end.

When installing a rotary converter, is it good practice to insulate the frame of the rotary from the ground? F. L. D.

There may be instances where this is desirable; but as a rule, rotary converters are not thus insulated, since by insulating the frame the danger to the attendant is increased, although the strain on the insulation of the windings is thereby decreased.

Can two direct-current motors of the same voltage but of different sizes and speeds be belted to the same shaft, provided the pulleys are of the proper size? B. M. P.

Yes. The size of the pulleys should be calculated, however, on the basis of the actual speeds of the motors under full load. Any discrepancy in the speeds at lighter loads would then only result in dividing the load unequally without harming the motors.

Can I cut out a damaged armature coil in a revolving field three-phase alternator, or should the coil be taken entirely out of the slots? M. T. T.

The damaged coil may be disconnected from the armature circuit and its place bridged over with a piece of wire; it would be better, however, to remove the coil entirely, as any e.m.f. induced in it may damage it further, and this may extend to neighboring coils.

The brushes of a motor chatter and spark to a disagreeable extent. What is the cause of this, and how may it be remedied? J. C. B.

The copper of the commutator evidently wears quicker than the mica used in insulating the bars. The difficulty may be remedied by filing out the mica between the bars with an ordinary three-cornered file until the file touches on both bars, or until the edges of the mica strips are no longer flush with the brush tread of the copper segments.

What is meant by a sneak current, and why should it be avoided? T. M.

A sneak current is a current from some outside source that finds its way into a telephone circuit. It is usually of so small a value that its presence is not readily detected. The danger of sneak currents lies in the fact that if they are allowed to pass through the switchboard or any kind of telephone coil for any length of time, they develop sufficient heat in the coil to ruin the insulation, and in some cases they have been known to start a fire.

How can I remove the burn around the circuit-breaker from a slate switchboard? L. A. B.

The burned portion should first be rubbed with sandpaper until clean. The spot should then be coated with a filler which will not carry current. When this is dry the uneven surfaces should be levelled with good, hard putty. This should then be rubbed down with pumice stone, cleaned and colored. Then apply varnish, and when this is thoroughly dry, polish with butter of antimony and raw oil.

How is it possible to pump water into a boiler by means of its own steam pressure? What prevents the water from running back after the stroke of the feed-pump is finished? W. W.

The steam cylinder of a boiler feed pump is always larger than the water cylinder, and the total steam pressure acting on the steam piston and tending to force the water into the boiler is greater than the total resisting pressure acting on the water plunger. The water is prevented from returning to the pump when the stroke is finished by means of a check valve which is opened by the water forced into the boiler; but is closed by the boiler pressure during the return stroke of a single-acting pump.

Is it economical to install a storage battery to work in conjunction with a power house having moderately fluctuating loads? A. R. M.

The advantages of a storage battery in this case depend to a great extent upon the total capacity of the station. If your plant is small a battery is useful to carry the peak and light loads, and also as a stand-by in case of accident to the generating apparatus. If your station is a large one, the principal use of a storage battery is to take the momentary fluctuations, but if these are small compared with the size of a generating unit, the first cost and maintenance of a battery large enough may be too great to warrant its installation. A battery is, however, useful to render the service immune from interruptions since it can supply sudden demands, and the value of this may entirely outweigh the question of first cost and economy.

I oftentimes have occasion to charge storage batteries from a number of different circuits about the city, and would be obliged if you would give me some ready method of determining the polarity of the circuit. R. S.

You may determine the polarity of a circuit with ordinary litmus paper where the difference of potential is as low as one volt; a red spot appearing at the positive terminal. Paper moistened with a solution of iodic arsenite of potassium yields a black color at the positive terminal. Berghausen's polarity indicator consists of a solution of phenol phthalein and chloride of sodium or sodium sulphate; this gives a red color at the negative terminal which vanishes when the current is off. There are a number of other solutions on the market. Small squares of white blotting paper saturated with a solution of iodine of potassium and allowed to dry form very convenient polarity indicators. When making a test moisten a piece of the paper with water and press it against the terminals of the circuit. The positive terminal will change the color to a pronounced brown while no change of color will be evident at the negative terminal.

MANUFACTURING PLANT OF THE B. F. STURTEVANT COMPANY AT HYDE PARK, MASS.

As the growth and development of the B. F. Sturtevant Company continued in its plant at Jamaica Plain, Mass., the conclusion was gradually reached that the available facilities could never meet the requirements of a thoroughly up-to-date manufacturing establishment.

While negotiations were in progress for the purchase of a new location near Boston the works at Jamaica Plain were visited by a serious fire, April 14, 1901, which destroyed a large amount of machinery and threatened to severely cripple the business. This disaster naturally hastened the final acquirement and development of a site for the new plant. This is now located in the town of Hyde Park, Mass. The new location is only six miles from the old plant and has a frontage of about 1300 feet upon the freight yard of the N. Y., N. H. & H. R. R., at Readville Station. One side of the lot is bounded by a plentiful stream and the adjacent shore is at a level of more than 10 feet below that of the yard and buildings, thus providing sufficient space for dumping waste material for years to come.

The arrangement of the buildings is such as to limit as far as possible internal transportation to straight line movements. A complete industrial railway system of 2 feet gauge connects all departments; spur tracks from the New Haven yards facilitate the movement of raw material and products; traveling cranes, pneumatic, electric and manual hoists and electric elevators are scattered throughout the works and all machinery is motor-driven with the exception of the ventilating fans and air-compressor equipment.

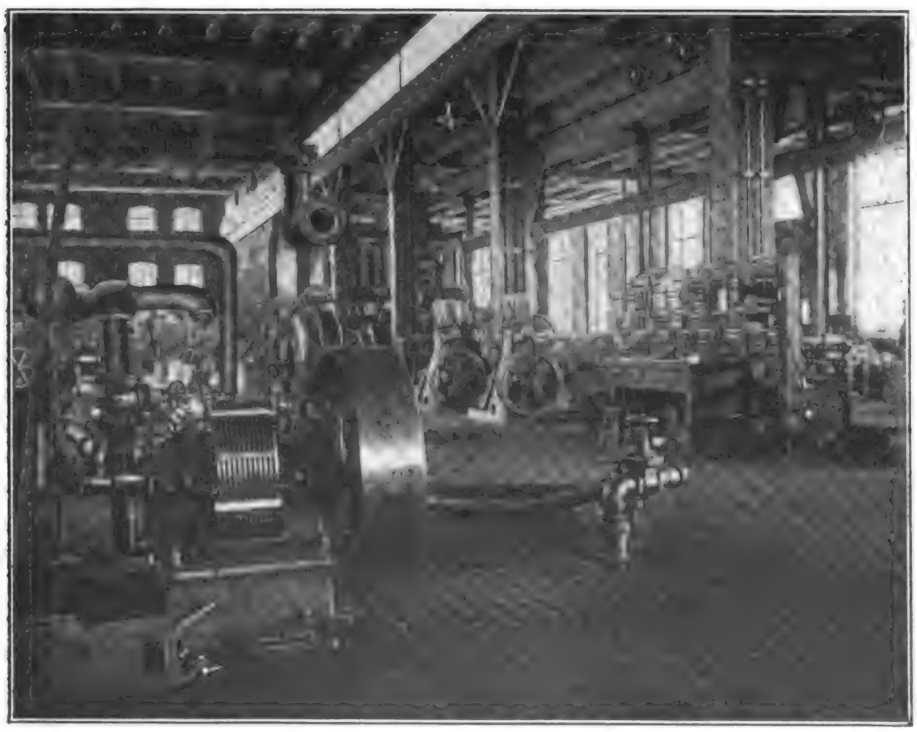

FIG. 1.—CORNER OF TESTING PLATE AND SWITCHBOARD FOR SAME.

The power plant was located about 250 feet north of the shop buildings, so that the latter might be amply extended, with the former still near enough to reduce to a minimum the expense of conveying condensing and other water, transmitting steam, electricity and compressed air. The boilers are of Stirling make, with a total rating of about 1000 horse-power, and the plant naturally contains mechanical draft apparatus and a Sturtevant economizer. The generating sets were built by the company and consist at present of a 100-kw. and a 250-kw. machine. The engines are of the vertical, cross-compound type and are operated condensing. A concrete tunnel 6 feet 6 inches high and 5 feet wide connects the power house with the various shops, and it contains all piping and transmission circuits. It is lighted by incandescent lamps. The power house supplies all the steam used in the different buildings through an 8-inch, 160-pound line which branches to a minimum diameter of 2 inches in the pattern building with 2½ inches in the office building, and a 14-inch pipe carrying 5 pounds pressure to the various heating coils. The high-pressure steam is reduced to 80 pounds for the operation of fan engines, and the latter exhaust into the heating system, which is a typical Sturtevant installation. The testing department uses 160 pounds steam in its work upon compound, direct-connected sets.

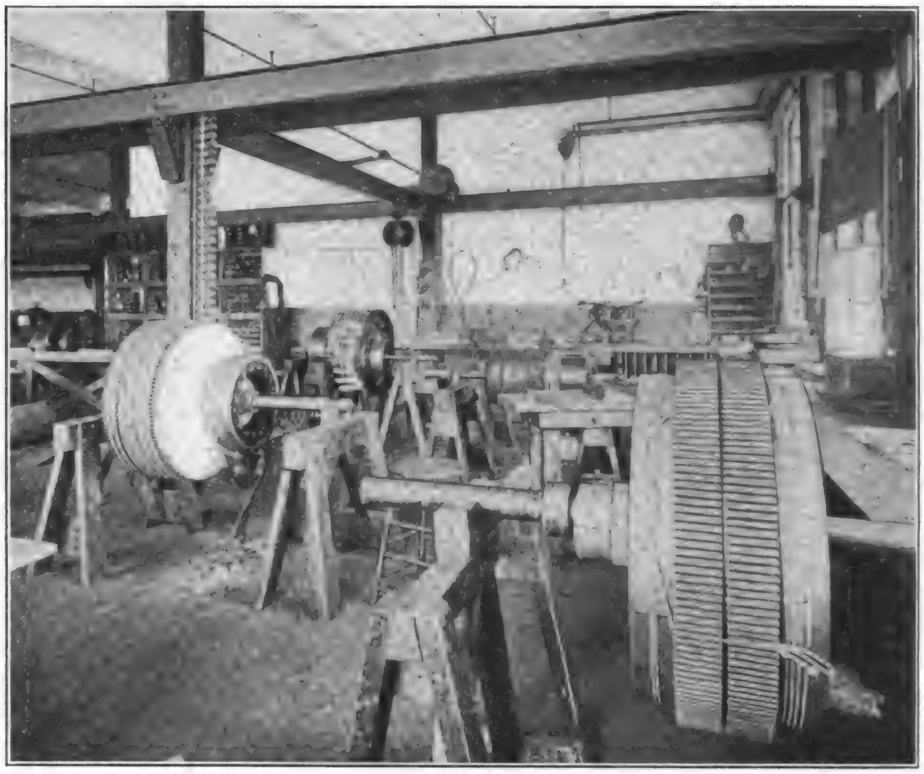

FIG. 2.—ARMATURES BEING WOUND IN ELECTRICAL DEPARTMENT.

All the electrical distribution is carried out upon the two-wire plan at 220 volts direct current for both power and lighting. The largest cable used in the ducts is 1,500,000 c.m. A maximum drop of 2½ per cent was figured between the power house and the load. General illumination is supplied by General Electric 110-volt enclosed arc lamps run two in series, and all special lighting is by 16-c.p., 220-volt incandescent lamps. The air compressor in the power house is a Laidlaw-Dunn-Gordon machine with compound steam and compound air cylinders, distributing air at 100 pounds pressure throughout all the shops. Junctions in the main 6-inch supply pipe provide for the different buildings, which are supplied by 3-inch pipes. Tools are supplied through 1-inch pipes and the air is widely used in drills, hoists, riveting hammers, chisels, snaggers, for blowing out generators, motors and cylinders.

There are about 100 electric motors in the plant, varying in size from ¼ to 40

horse-power, all being of the company's make. Both group and individual driving of machines are in use. The tools are in general arranged to facilitate the direct progress of the work from the receiving ends of the shops toward the finished stores, erecting, testing and shipping departments. Machines, group-driven, are as a rule operated in sets requiring about 20 horse-power, and a motor of this capacity is assigned to all such groups. The machines are as far as possible arranged in duplicate and space is left for additions in supplementary parallel rows. All motors above 10 horse-power are equipped with General Electric circuit-breakers, enclosed fuses being used in smaller sizes. Starting boxes and controlling switches are located either on posts close by the machines, or in the case of some connected motors, upon the machine frames. Practically all the motors used in group driving are hung from the ceilings. The starting boxes are equipped with self-closing doors lined with asbestos. The bench lighting is arranged so as to give each employe as far as possible left shoulder illumination. Incandescent lamps for this work are hung from porcelain rosettes attached to a horizontal wooden strip suspended upon wall brackets. The strip is about 10 feet above the floor and the lamps, with attached downward reflectors, are about 1 foot above the average man's head. At various points in the factory where power is required for testing or other temporary purposes, plug boxes are installed upon certain of the vertical columns within easy reach of the floor. These boxes are fitted with one jack on each side and with fuses or other circuit-breaking devices inside, self-closing doors and asbestos lining.

Several motors are effectively used in the pattern shop and foundry. In the former, the flask shop band, cross-cut and splitting saws, boring drill machine and lathe are all driven by a 10-h.p. motor, while the carpenter shop or pattern-making division proper is equipped with two 10-h.p. motors which operate two band saws, a buzz planer and a double surfacer, five lathes, a drill press, core box machine and wood trimmers. Both these motors are required in ordinary work, one serving as a possible relay in case of accident. In the foundry, a 15 and two 20-ton Whiting electric traveling cranes are in regular use upon the two runways, and the floor between the runways is served by a number of 1½-ton electric traveling hoists with 10-ft. span, built especially for the work by the company. The cupolas are two in number, of Whiting make, 56 in. and 72 in. in diameter. The former is supplied with air by No. 8 Sturtevant pressure blower driven by a 30-h.p. motor, and the latter by a No. 10 blower driven by a 40-h.p. motor. In the brass foundry, blast for the furnaces is supplied by a No. 3 Monogram blower, and the entire machinery, consisting of a sprue cutter, a magnetic separator, a tumbling barrel and emery wheels, is driven by a 5-h.p. motor attached to the wall. A 5-ton three-motor electric Whiting crane serves the principal portion of the floor in the cleaning room. In the core department is a Blake wire straightener, driven by a 5-h.p. motor. All the elevators in the works are electrically driven by Sturtevant motors. The principal traveling cranes are all of Whiting make, with Sturtevant motors.

FIG. 4.—ELECTRIC FANS UNDER TEST IN ELECTRICAL DEPARTMENT.

Armature punchings and commutators are built up in the uppermost floor of the fan and heater shop, adjoining the testing building. The storage of commutators and parts is effected on divided pigeon holes, numbered according to the shop scheme for quick reference. The armature baking room is 40 ft. square, entirely fireproof, and it contains two steam heated baking ovens, fitted with sheet iron doors and discharge ducts. At the other end of the building is the special store room for electrical supplies. The balance of this floor and of the intermediate floor below is de-

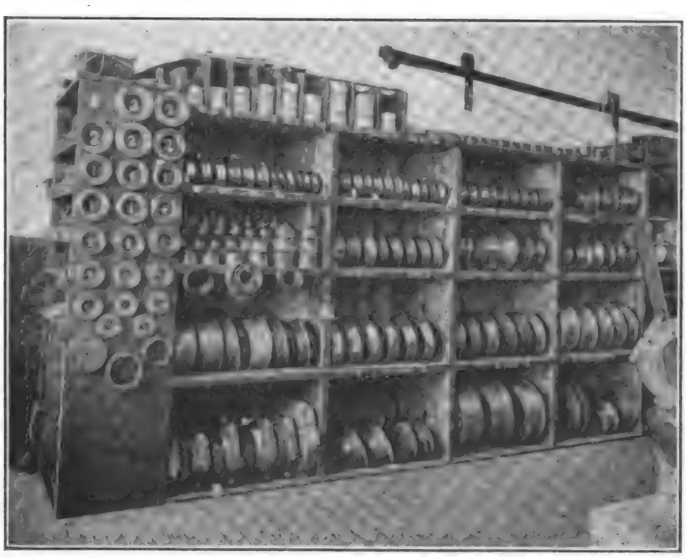

FIG. 3.—COMMUTATOR RACKS IN ELECTRICAL DEPARTMENT.

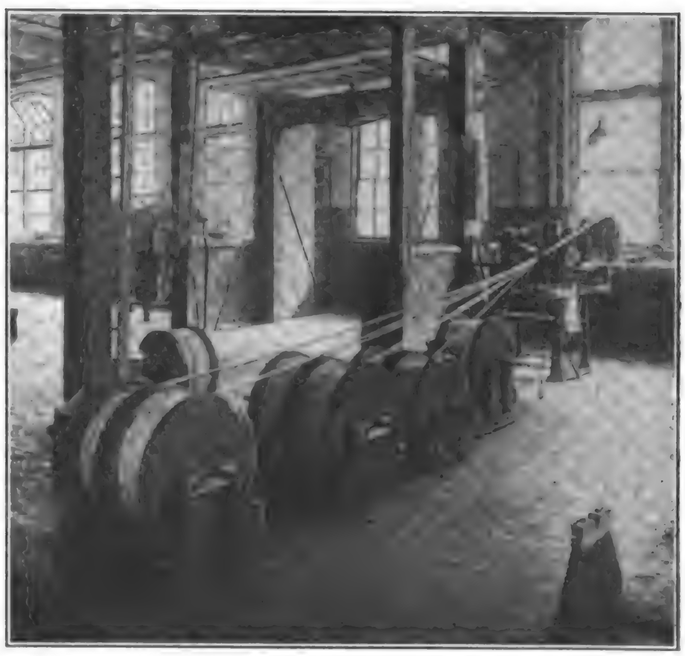

FIG. 5.—WINDING MACHINE IN ELECTRICAL DEPARTMENT.

voted to winding, assembling and testing.

Heavy testing is mostly carried out upon the first floor. Here is a testing plate 30 ft. x 60 ft., completely equipped with steam and electrical connections; engines may be run condensing or non-condensing, and efficiency tests, compounding tests and heat runs conducted. Flexible and rigid pipe sections, portable belted tachometers, steam trap and electrical testing connections, movable racks of lamp banks, scales and water rheostats complete the equipment.

The winding department on the third floor is arranged conveniently with bench scales, reel frames, magnet connections at intervals of 20 ft., lamp banks and armature racks. The latter are group-driven, and the daylight supply is admirable. The testing magnet is mounted on a bracket attached to an upright column and is permanently driven by belting from an overhead line shaft. The special trucks used in handling armatures also deserve mention. Small traveling cranes and hoists are constantly in use on this floor, which is equipped with a floor plate for testing motors and blowers. A complete permanent switchboard forms part of the testing room equipment and all direct-current voltages from 80 to 550 are available for testing, as well as alternating voltages up to 2,500, the latter being used in insulation breakdown tests. On the rear of this board are circular bus-bars, to which flexible cables may be clamped as may be convenient. The variation in voltages is obtained by operating motor-generator sets situated at the left of the switchboard previously mentioned. Portable test tables and lamp banks are available; a water rheostat plant is located on the roof, and instruments are stored in the office, which is being equipped for B-H curve tests upon samples of iron used in the machines. The foundry of the company supplies this material, which runs evenly most of the time, but which needs checking magnetically now and then.

The tests performed upon the equipment vary according to the specifications of the purchaser, but all the generating sets and motors are built to withstand the severe requirements of the U. S. Navy. All apparatus sold to the government is subjected to the exhaustive tests which the departments specify; but even commercial apparatus is put through heat runs, insulation, mechanical balances, frictional and commutating tests at the proper loads.

The architects and engineers for the B. F. Sturtevant Company were Messrs. Lockwood, Greene & Company, of Boston. The construction of the plant, including the design of the entire industrial equipment, the purchase of all building material, the hiring of all labor, was carried out by the Sturtevant company.

NEW WESTINGHOUSE RAILWAY MOTOR.

The Westinghouse Electric & Manufacturing Company has brought out a new line of motors for heavy traction, the smallest motor of the new design being rated at 75 horse-power, and the largest at 200 horse-power. Limitations are naturally placed on the size and construction of a motor by the amount of available space on the truck of the car; therefore, the frame of square cross-section was adopted as utilizing this space most advantageously. All motors in this line have cast-steel frames split at an angle of 45° with the horizontal. The axle bearings are carried by the lower half of the field frame and are divided at an angle of 35° with the perpendicular, so that the weight of the motor is supported almost entirely by the part of the frame extending over the axle rather than by the axle cap bolts. By lifting off the upper half of the field casting the armature may be removed from the frame without taking the motor from the truck; or the motor may be removed from the truck by simply taking off the gear case and axle caps. Three bales, conveniently located, make handling of the motor easy. Bolts with nuts and lock washers hold the two halves of the frame together and the axle caps in proper position. Housings for the armature bearings are circular in form and are turned slightly larger in diameter than their seats in the frames so that when clamped in place, all the advantages of a press fit are obtained. Finished shoulders on the housings prevent any lateral movement and also take the entire end thrust of the armature instead of imposing this severe strain on the clamping bolts. Two bolts through the frame at each end prevent the housing from turning. The armature bearings are made of phosphor-bronze bushings finished all over, with a 3/32-in. lining of babbitt metal. If from neglect the bearing should become so hot as to melt the babbitt the armature would be supported on the brass shell and would not strike the poles. Both oil and waste lubrication are provided. The waste comes in contact with the bearings on the low-pressure side and is supplied with oil from separate pockets from below; in this way it is filtered before reaching the bearing. The amount of oil in the reservoirs may be gauged so that it may be kept at the proper level for economical service. It is stated that with intelligent care these bearings will run 100,000 to 150,000 miles. The axle bearings are similar in construction to those of the commutator, except that split bushings are used. Here also lubrication is by means of oil and waste, the oil being supplied from below. The laminated pole pieces are bolted to the top, bottom and sides of the motor frame, which, being almost square in cross-section, permits the use of flat field coils. These coils are wound of copper strap insulated between turns with treated asbestos ribbon and then carefully taped and given repeated dippings in specially prepared insulating compounds and varnishes which make them moisture-repelling and able to stand internal heat. Brass hangers hold the coils in place independently of the poles. The shaft is forced into the finished armature and keyed thereto and may be removed, should necessity arise, without disturbing the windings or commutator. The armature coils are strap-wound and

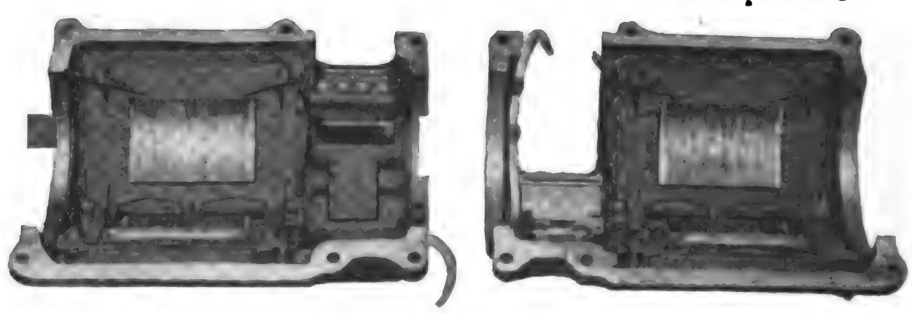

FIG. 2.—INTERIOR VIEWS OF 200-H.P. RAILWAY MOTOR.

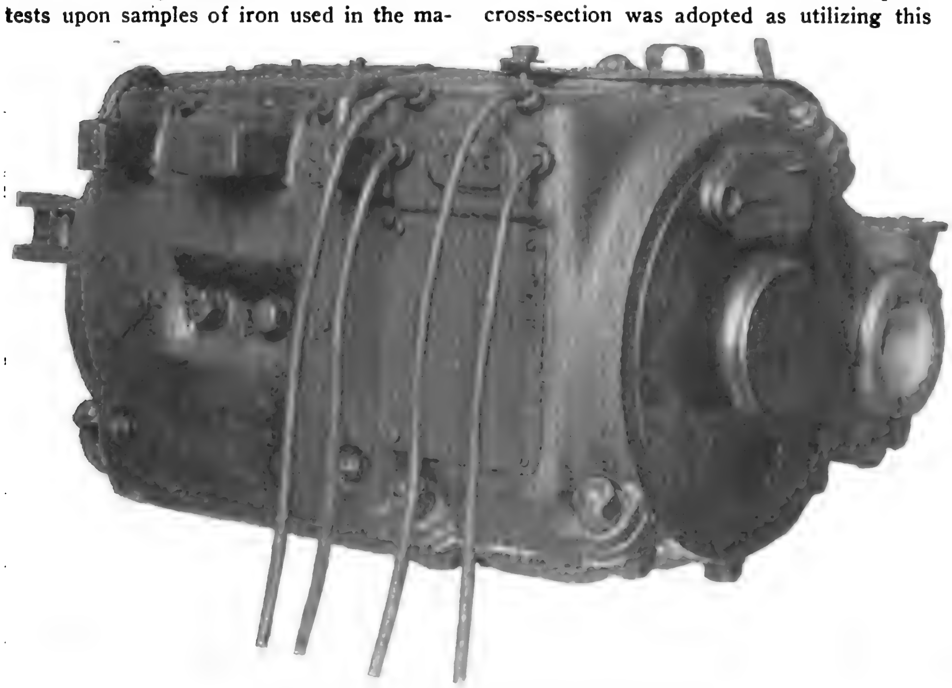

FIG. 1.—EXTERIOR VIEW OF RAILWAY MOTOR.

made in two parts. As the top coils are more liable to injury this design makes it possible to remove the damaged part without disturbing any other part of the winding. The coils are liberally insulated with mica, and sealed and further insulated by dipping in varnishes which are oil-proof and moisture-repelling. On each end the armature slots are made deeper and wider, thereby providing space for mica cells, which greatly reinforce the insulation at these points. As a further protection fibre strips are taped to the upper sides of the top coils. A bell-shaped flange at the pinion end and a cylindrical flange on the commutator end form rigid supports for the windings. Countersunk bands of steel wire on the core hold the coils firmly and securely. Openings through the spider and core allow a free passage of air, which is thrown forcibly against the field coils, thus maintaining a low temperature throughout the motor. The brush holders are of the sliding type with springs of phosphor-bronze held in a harness which definitely fixes the radius of action of the spring tip, and is so constructed as to practically eliminate friction between turns, making it possible to provide a large number of turns, which gives a very uniform pressure upon the brush over a considerable range without requiring adjustment. The tension of the spring may be adjusted without removing the holder from the motor. The brush holder proper is bolted to an insulated guide and may be removed without disturbing the insulation or connections. Leads of flame-proof flexible rubber-covered cable are brought out at the front of the motor over the commutator through insulating bushings. Access to the brushes and brush holders is provided through a large opening in the frame over the commutator which extends well down the side, making inspection easy from the pit. A hole in the rear end bell and an opening under the commutator provide means for inspecting the clearance between the armature and field poles. Pinions used on these motors are machined from steel forgings and held on tapered seats by keys, nuts and lock washers. Gear cases are made of malleable iron and divided along the center line of armature and axle. They are supported only at the ends, which does away with all side strains which are responsible for so many broken gear cases. Nose suspension with safety lugs is used for all motors of this design.

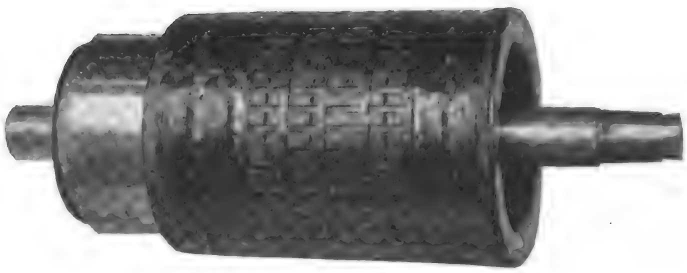

FIG. 3.—ARMATURE OF RAILWAY MOTOR.

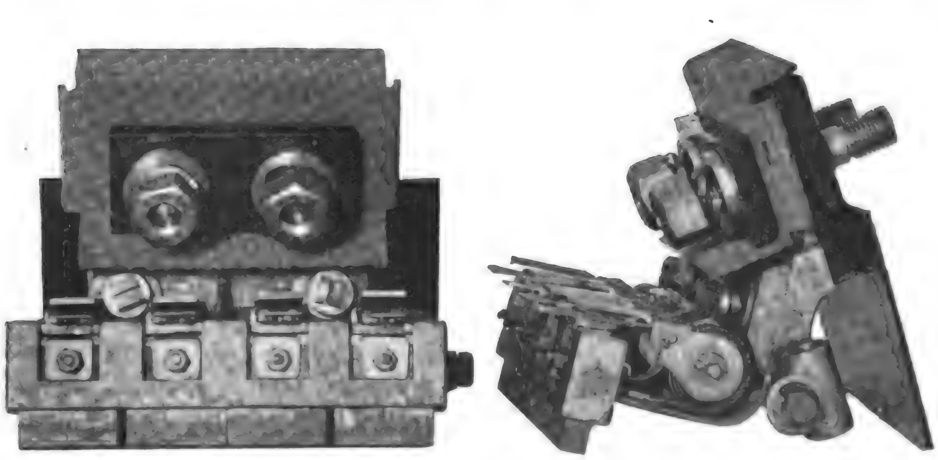

FIG. 4.—FRONT AND SIDE VIEWS OF BRUSH-HOLDER.

SINGLE-PHASE RAILWAY FOR SPOKANE.

A contract has just been closed with the Spokane & Inland Railway Company by the Westinghouse Electric & Manufacturing Company, of Pittsburg, Pa., for the equipment of an electric road, the present terminals of which will be Spokane, Wash., and Moscow, Idaho, 146 miles apart. The roadway is completed from Spokane to Waverly, a distance of 34 miles, and operation will be begun on this as soon as possible. The road is a home enterprise, the stock being held entirely by men living in the district through which the line passes. The directors of the company are J. P. Graves, president; F. A. Blackwell, vice-president; F. Lewis Clark, John Twohy and Alfred Coolidge.

In selecting the equipment for this road, both the direct-current and the single-phase systems were considered, but, after careful comparison the single-phase alternating-current system was adopted. It is claimed that not only did the estimate show a large saving in initial investments and in annual operating expenses in favor of the single-phase system, but a form of heavy traction was made possible which would be practically unfeasible with direct-current equipment. Besides the passenger traffic the company is preparing to do a heavy freight business and also carry mail.

Power for the operation of the road will be purchased from the Washington Water Power Company, which will supply three-phase current at 4000 volts, and 7200 alternations, to a frequency-changing station approximately 1½ miles from the generating station. Seven 750-kw., oil-insulated, water-cooled transformers will step down the voltage from 4000 to 2000 volts, the potential for which the induction motors of the frequency-changing sets are wound. There will be four of these motor-generators or frequency-changers of 1000 kw. capacity each at normal rating. Each consists of a 1000-h.p., three-phase, 2000-volt, 60-cycle induction motor, a 1000-kw., single-phase, 2200-volt, 25-cycle, revolving-field alternator, and a 750-h.p., 550-volt, direct-current generator which is to float on the storage battery acting alternately as a motor and generator. The three machines will be mounted on a single bed plate with seven bearings. Exciting current for the alternators will be supplied by three sets, each consisting of a 75-h.p., three-phase, 2000-volt induction motor and a 50-kw., direct-current generator.

Nine 675-kw., oil-insulated, water-cooled transformers will step up the voltage from 2200 to 45,000 volts, at which pressure it will be transmitted to fifteen static transformer sub-stations, each containing two 375-kw., 45,000-6600-volt, oil-insulated, self-cooling transformers. A 23-panel switchboard, electrically-operated, automatic oil circuit-breakers, and protective apparatus complete the equipment of the frequency-changing station. Low equivalent lightning arresters and choke coil are provided for both the primary and secondary circuits in all sub-stations.

The transmission lines will consist of two No. 2 copper wires and the trolley will be of the standard catenary construction, using a No. 000 wire and carrying current at 6600 volts.

Each passenger car will be equipped with four 100-h.p. motors, capable of maintaining a schedule speed of 35 to 40 miles an hour. In the freight service four 150-h.p. motors will be used on each car. For the heavy freight service double locomotives weighing approximately 70 to 80 tons will be used, each consisting of two parts and each part a complete 35 to 40-ton locomotive. Two or more of these locomotives may be coupled together and operated from the front cab as a single unit. The motor cars and locomotives will all be operated by multiple unit control. The motors will operate under three different conditions: 6600 volts alternating current in the interurban districts, 700 volts alternating current in the smaller towns and 575 direct current in the city of Spokane.

New Apparatus and Appliances

A NEW RECORDING WATT-HOUR METER.

The General Electric Company has recently placed on the market a new type of recording watt-hour meter identical in principle with the earlier forms of Thomson recording watt-hour meters, but differing widely in structural details. This new meter is known as the Thomson recording watt-hour meter, Type C. In general the meter has been made simpler and more compact. The first change in construction to be noted is the method of support. The upper lug is key-holed, and the lower right-hand one slotted. This permits rapid and accurate leveling as the screw can be inserted and the meter hung thereon approximately level. The final adjustments can then be made accurately. The cover is fastened with studs and wing nuts and may be moved directly toward the front, permitting the installation of a large number of meters where space is limited. The sealing wire is passed through the wing nuts and their respective studs necessitating the use of but one wire, and prevents tampering without detection. A felt-lined groove surrounds the edge of the cover and the leading-in holes for the wires are covered with the same material, excluding both dust and insects. In the meter proper a number of improvements have been made. The register is of the four-pointer type with large, clear dials registering directly in kilowatt-hours in all sizes up to 30 kilowatts. Except in the larger

FIG. 1.—RECORDING WATT-HOUR METER.

sizes no dial constant is necessary. Where a dial constant is required a decimal constant has been chosen so that the actual energy unit remains the same, and the correct reading is easily obtained by adding ciphers to the dial reading as the constant requires. The lower bearing is made of sapphire, or in capacities above 50 kilowatts, of diamond. The shaft is tipped with a brass pivot fitted with a very finely polished steel point which, with the jewel cup, forms an ideal bearing surface. The armature shaft is tubular. On the upper end of the shaft and very carefully insulated from it, is the commutator. This is but one-tenth of an inch in diameter, and with the gravity-controlled brushes,

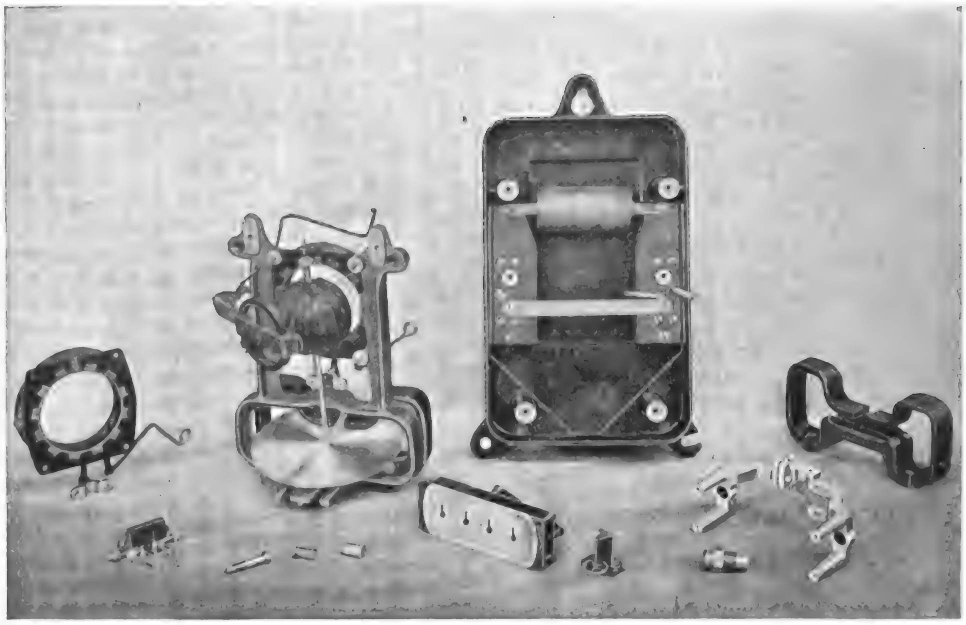

FIG. 2.—PARTS OF RECORDING WATT-HOUR METER.

reduces the friction at this point to the minimum. For protection during shipment and any subsequent transportation the Type C meter is provided with a clamping device which holds the moving element securely in position. This consists of a brass cap which is normally drawn down and held by the jewel screw against the force of the lifting spring. When drawn down the moving element is free to rotate, but when the jewel screw is backed out the cap is released and the spring causes it to lift the moving element from the jewel and hold it firmly. The entire mechanism is assembled upon a skeleton casting which in turn is fastened within the meter casing. By removing four screws and disconnecting the windings from the terminals the mechanism may be removed for inspection and repair. The plane of the field coils is parallel to the back of the meter, hence by the removal of the front series coil and the register, and the loosening of the shunt field coil, the moving element may be taken out. This does not necessitate the removing of the magnets and therefore full-load calibration is unaffected. An automatic link between the worm wheel and the register permits removal and replacement of the latter without in any way affecting the proper mesh of gear and worm. The four magnets are permanently fastened together in sets of two and each set may be removed from its supporting shelf by the loosening of two screws. The armature is spherical and revolves within circular field coils. It is wound from very fine wire upon a paper shell and the field windings are of copper ribbon. The damping magnets are subjected to a rigid process of magnetization and ageing to insure absolute permanence. The peculiar design of the field coils and armature of the Type C meter gives, it is claimed, the greatest possible torque combined with minimum losses and weight of moving element. Although designed primarily for use upon direct-current circuits, the Type C Thomson recording watt-hour meter may be used on alternating-current circuits regardless of frequency or wave form, and if properly lagged upon inductive circuits without recalibration or adjustment. Having no iron in its construction, the Type C meter is not subject to hysteresis action. The meter is manufactured in capacities ranging from 5 to 600 amperes, inclusive, two-wire; and 5 to 300 amperes, inclusive, three-wire; and for potentials from 100 to 600 volts.

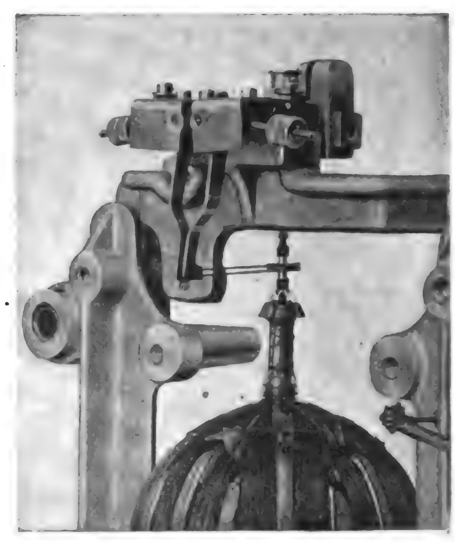

FIG. 3.—INTERIOR OF RECORDING WATT-HOUR METER, SHOWING SMALL COMMUTATOR AND GRAVITY BRUSHES.

AUTOMATIC BELT-TIGHTENING IDLER.

A newly designed automatic belt-tightening attachment for the standard Crocker-Wheeler Form L motor is shown in Fig. 4. It may be used wherever the limited center distances between pulleys require an

increased belt contact on the pulley surfaces. This device is designed so that it may be attached by the customer at any time to any L motor having a rear-end shield. Its principal parts are the idler pulley, arm and block, spring-stud and block and the adjustable spring and hook

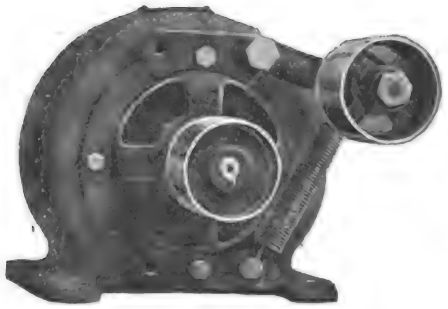

FIG. 4.—BELT-TIGHTENING IDLER.

for connecting them. The idler pulley and arm are pivoted on a stud which may be screwed into either one of two tapped holes in the block. The block itself may be attached to the motor in any one of four positions by a special screw replacing any one of the four machine screws holding the rear shield to the motor frame. Eight locations are thus afforded for the pivot of the idler arm.

IMPROVED RENEWABLE SEAT AND DISC GLOBE AND ANGLE VALVES.

Crane Co., Chicago, has brought out a complete line of improved renewable seat and disc globe and angle valves, some of which are illustrated by Figs. 5 to 9 herewith. These valves are suitable for working pressures up to 250 pounds and are tested to 700 pounds pressure per square inch.

As the accompanying cuts will show, they embody several new and valuable features in their construction. The renewable parts are made of hard and superior composition, and are suitable for hard work, where extreme pressure is used and where the wear and tear on the valve is most severe. By unscrewing the nut on the bottom of valve all parts are accessible and removable from the top, thus making is convenient to substitute a new seat or new disc when required, or to replace any worn part. The construction of the valves is

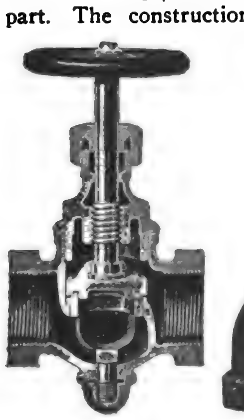

FIG. 5.

FIG. 6.

such that they may be packed when open without steam escaping. The Crane patent renewable seats and wedge straightway valves are made with copper seats and hard metal wedge; they are suitable for working pressures up to 250 pounds and are tested to 800 pounds pressure per square inch. The ready method of inserting these renewable parts and the wide range in the use of these valves on all kinds of severe

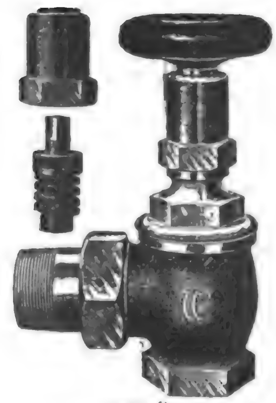

FIG. 8.

service will recommend them to all users. Soft metal rings or seats will be furnished for water or air, when so specified. The Crane "self-packing" globe and angle and radiator valves are made with Jenkins disc and non-rising stem and satisfactorily sup-

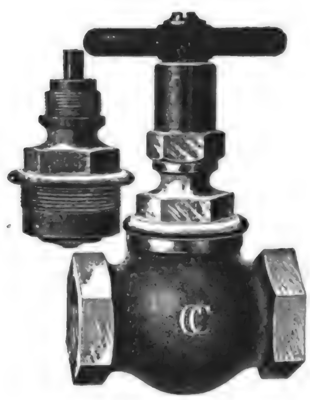

FIG. 9.

ply a demand for valves embodying this very desirable self-packing feature. All users of radiator valves know that leaky stuffing boxes are a source of a great deal of annoyance, caused by the escape of steam and water. In the Crane self-packing valve, a piece of vulcanized rubber is introduced between two metallic parts, which makes a perfect seat. The threads on the bonnet of

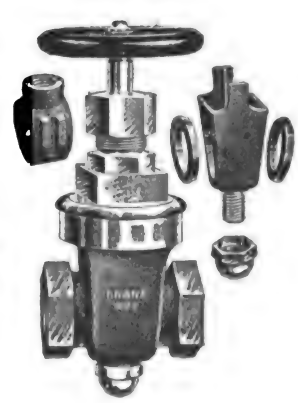

FIG. 7.

these valves are the same size as those in the Jenkins disc valves, made by Crane Co., so that the old style trimmings may be replaced with this new self-packing device, without removing the valve.

WEATHER-PROOF SOCKET PLUG.

The socket plug shown in the accompanying illustration has been designed as a substitute for an incandescent lamp in places where light is not needed throughout certain portions of the year, as in parks, summer resorts, and for sign work. Under

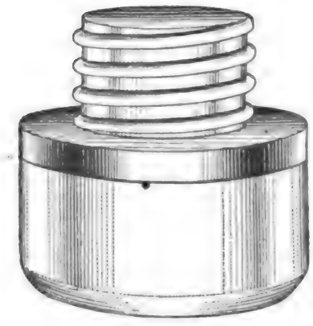

FIG. 10.—WEATHER-PROOF SOCKET PLUG.

ordinary circumstances when the lamps are removed, the sockets, which are left exposed to the elements, become badly corroded and cracked. The breakage resulting from this cause frequently amounts to a very large proportion of the total installation of sockets and receptacles, and the cost of new ones, together with the price of labor necessary to replace them, forms a considerable item of expense. The socket plug illustrated is thoroughly weather-proof. A soft rubber gasket is interposed between the plug and socket, thus making a watertight joint. These plugs are manufactured by the Weather-Proof Socket Plug Company, of Philadelphia, Pa.

KNOWLES EXPRESS PUMP.

The International Steam Pump Company, New York, has bought out a very compact high-speed pumping outfit, known as the Knowles "express" pump. Fig. 11 herewith illustrates one of these pumps, which was installed in the celebrated Comstock mine. The pump is direct driven by an electric motor, the armature of the lat-

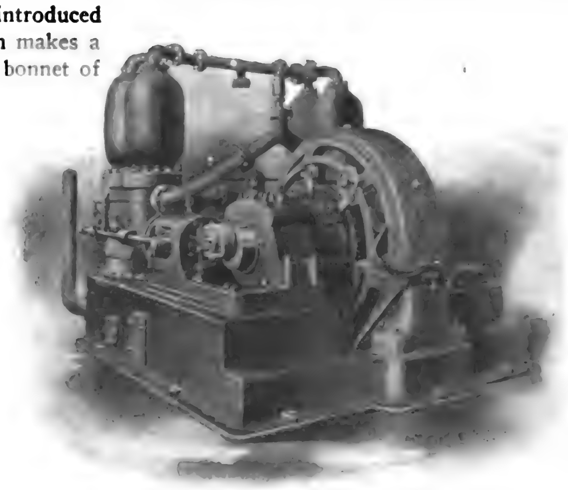

FIG. 11.—KNOWLES EXPRESS PUMP.

ter being mounted upon the main crank shaft without intermediate gears or belting, resulting in a mechanical efficiency, it is stated, of over 93 per cent.

High-speed pumps are usually construct-

ed with mechanically operated valves; some designers advocate mechanically closing both inlet and outlet valves, while others favor mechanical opening. The valves of this pump are of the simple automatically-operated type, the complication of valve-operating gear being avoided successfully. The pump is of the duplex double-acting, outside-packed-plunger type, having cranks at right angles, and the motor armature mounted upon the main shaft,

FIG. 12.—MICANITE CANOPY INSULATOR.

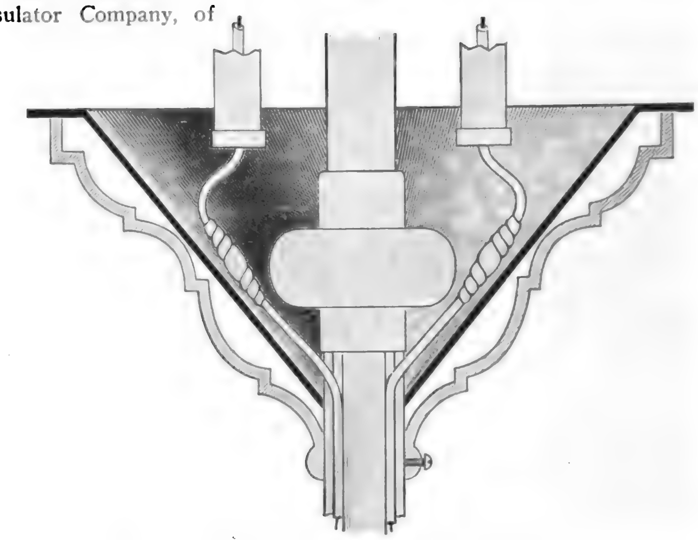

FIG. 13.—MICANITE INSULATOR IN PLACE IN FIXTURE.

as already mentioned. The entire machine is self-contained, mounted upon a rigid box-girder frame and occupies a relatively small space. In a very carefully conducted test, the pump is said to have proved a success in every way, surpassing the expectations of the builders and the purchasers. The operation under all conditions

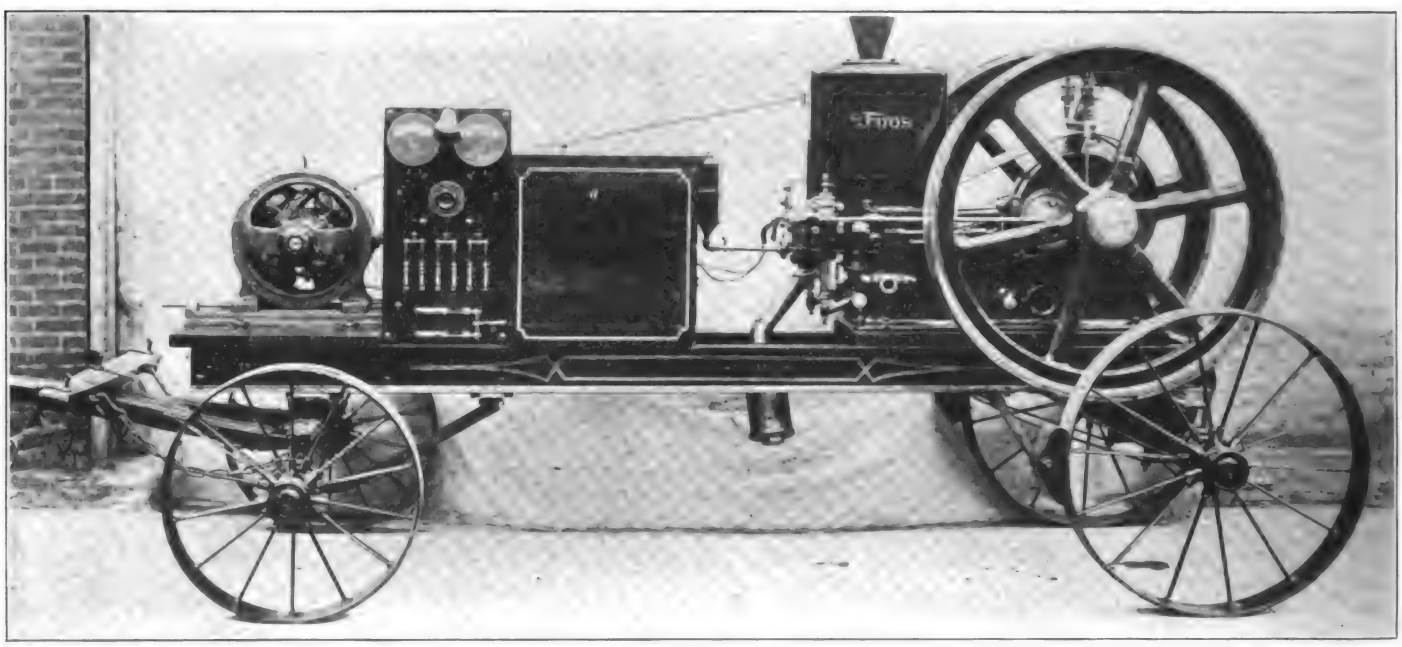

FIG. 14.—PORTABLE GASOLINE-DRIVEN ELECTRIC OUTFIT.

was practically noiseless, and was unaccompanied by the slightest shock or heating. The accompanying illustration represents a pump having plungers 3½ inches in diameter and a stroke of 5½ inches, the capacity being 250 gallons per minute against a head of 1000 feet. The full capacity and pressure for which the pump was built were attained at a speed of about 300 revolutions per minute. Pumps of this type are built in capacities of from 200 to 4000 gallons per minute, and for heads from 100 to 2000 feet.

MICANITE CANOPY INSULATOR.

As a means of eliminating the danger from fires due to defective insulation in electric light fixtures at the point where the wires project through the floor or wall and make connection with the wires of the electroliers, the Mica Insulator Company, of New York, has placed upon the market the "Young" canopy insulator shown in Figs. 12 and 13. The insulator is made of the well-known material "micanite," built up from large laminations of mica and moulded with both flange and taper into one solid whole. As seen from Fig. 13, the flange gives protection to the brass canopy from the surface to the ceiling or wall, thereby removing any possibility of a short-circuit between the two conducting wires, between either of the conducting wires and the canopy, or between the wires through the canopy to the ceiling. The insulator is claimed to be absolutely fireproof and the manufacturer says it has been approved by the National Board of Fire Underwriters.

PORTABLE FOOS GASOLINE ENGINE.

The accompanying illustration shows a portable electric outfit which is built by the Foos Gas Engine Company, of Springfield, Ohio, in various sizes for all purposes to which portable electric outfits are applicable. The outfit shown was supplied to a St. Louis concern for operating Cooper Hewitt vapor lamps for a portable photographic outfit. This, of course, is but one of many uses to which the output may be put, it being especially applicable during the winter season for thawing frozen water pipes by electricity. The engine is of the regular Foos type, having the well-known wipe spark igniter originated by this company, vertical positively driven valves, etc. The counterbalancing is accomplished by securing disks to the arms of the crank, leaving the wheels themselves in balance instead of casting weights on them. The result of this is shown very effectively by the steadiness of the portable outfits. The connections are all flexible and while the engine is free to move in all directions, its motion when under full speed is said to be practically unnoticeable. The accessibility of all the parts is one of the company's strong claims for the engine. The dynamo is of the Westinghouse make, as are also the switchboard, lamps, etc. The outfit shown is driven by a 7-h.p. engine.

INCANDESCENT CONCENTRIC DIFFUSER.

The incandescent concentric diffuser recently designed by the General Electric Company, and illustrated herewith, will doubtless prove of interest to those who have in the past been bothered by the problem of ade-

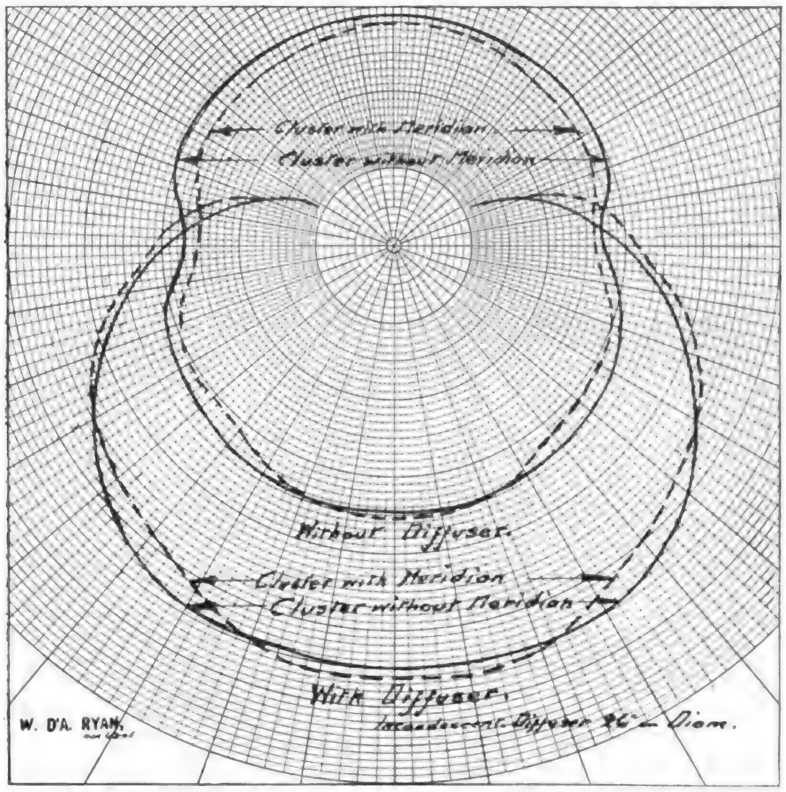

FIG. 15.—CHART SHOWING LIGHT DISTRIBUTION.

quate illumination under mezzanine floors, in basements, and similar places, where low studding eliminates the arc lamp, and large area the separate incandescent lamp. The diffuser is 26 inches in diameter, and is made of steel, coated with high-grade Aus-

FIG. 16.—CONCENTRIC DIFFUSER.

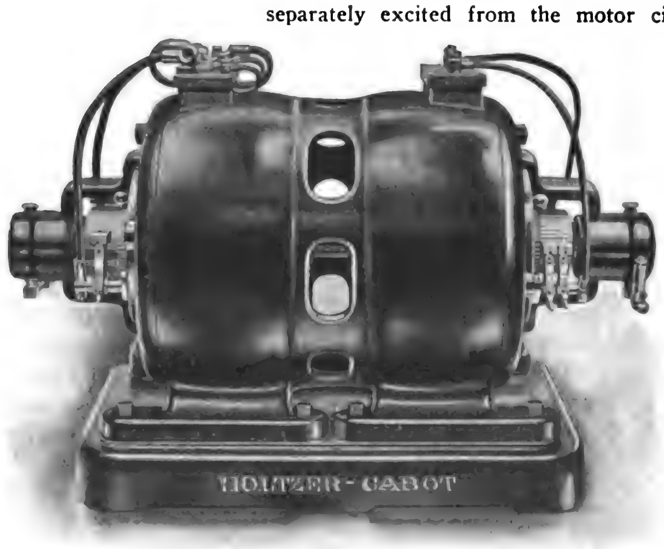

FIG. 17.—HOLTZER-CABOT MOTOR-GENERATOR.

trian air-dried enamel, which does not turn yellow, but it is claimed becomes whiter with age. The black deposit which usually accumulates on the ceiling above the lamp is received by the diffuser, from which it can be readily washed off, so the diffuser protects the ceiling in addition to giving an excellent distribution of light. The diffuser can be installed near the ceiling or on any extension rod, and any standard make of cluster with four-inch base can be used. The best effects have been obtained with one 25 or 50 c.p. Meridian lamp in the lower socket, and 3, 4, or 5 standard frosted 8, 16, or 32 c.p. incandescent lamps set radially, as shown in the illustration. From the chart it will be seen that the lower hemispherical candle power has been increased about 40 per cent and that the general distribution of downward light has been greatly improved. The radial lines shown in the chart correspond to angles of 10° in elevation, being marked in degrees of arc above and below the horizontal. The distance along these lines from the centre to a point on the curve represents the intensity of candle power in that direction. For instance, referring to the solid line curves, at 60° below the horizontal the cluster alone gives 85 candle power. This may be read either at the right or left hand side of the sheet. When the diffuser is used this is increased to 136 candle power, showing a gain of 60 per cent in this particular direction. While it is not advantageous to have all the light concentrated directly beneath the lamp, it is obvious that the most useful light is that thrown below the horizontal and that the light thrown above the horizontal cannot be utilized except as it is reflected downward from the ceiling.

HOLTZER-CABOT MOTOR-GENERATORS.

With the increase in use of the storage battery for launches, automobiles and private lighting plants has come the demand for a compact and efficient form of charging motor-generator. The advantages of the motor-generator over the dynamotor for work of this class are well known. In the first place, the primary and secondary circuits of the motor-generator may be much more effectively insulated from each other than can the windings of the dynamotor. Furthermore, the secondary voltage of the dynamotor form of machine cannot be regulated except by means of a line rheostat in the secondary circuit or a speed controller in the motor circuit using resistance in series with the armature, both these methods requiring expensive rheostats and producing a very uneconomical conversion. The motor-generator form of machine is more flexible in its adaptation to the engineering conditions. The voltage of the secondary may be regulated by the field rheostat and if the fields of the generator are separately excited from the motor circuit the voltage of the generator may vary from zero to the full potential of the machine, the current output and stability of voltage being retained throughout the entire range. The machines here illustrated have two bearings,

the two intermediate bearings being eliminated. The motor and generator cores are mounted on a common shaft, which is continuous. The speeds are low and the shafts quite heavy, so there is no tendency of the shafts to spring. The output of the machines ranges from 1/4 to 4 1/4 kilowatts. The machines may be wound for any direct-current circuit and the secondary wound to give any voltage from 20 to 500. The manufacturers are also prepared to supply machines of the same range and outputs of the two-bearing construction, but of the open type. There is no particular preference in favor of either type, although possibly the open type is a little more accessible. While these sets are intended primarily for charging batteries they have been found useful in other lines of work, particularly in telegraphic work for operating main and local circuits. These motor-generators are manufactured by the Holtzer-Cabot Electric Company, Boston, Mass.

ELECTROLIER KEY SOCKET AND COMBINED SOCKET AND SHADE-HOLDER.

The electrolier key socket, shown herewith, designed a short time ago by the engineers of the General Electric Company, Schenectady, N. Y., is very compact, and

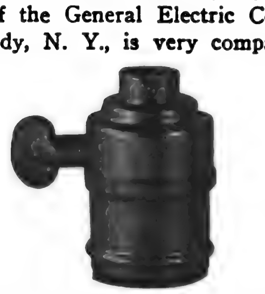

FIG. 18.—ELECTROLIER KEY SOCKET.

has a well-finished appearance, harmonizing with decorated electroliers. A metal key, thoroughly insulated from all live parts, accompanies the outfit. This key is removable, and an extension key may be used in its place. The combined socket and shade-holder shown in Fig. 19 is said to have met with the approval of many users. The

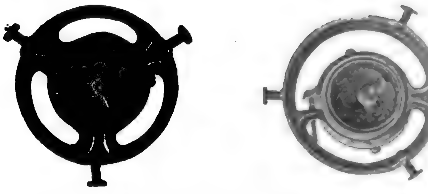

FIG. 19.—COMBINED SOCKET AND SHADE-HOLDER.

shade-holder in the new device is permanently attached to the socket shell in such a way that it cannot slide or turn. This, together with the fact that three points of support are afforded the shade, eliminates any sagging.

AMERICAN ELECTRICAL SALESMEN'S ASSOCIATION

During the convention of the Illinois State Electric Association at Peoria the salesmen present organized a new electrical society under the name of the American Electrical Salesmen's Association. Although nearly every other branch of the electrical industry has one or more organizations for mutual benefit, the salesmen, while frequently meeting at associations and elsewhere, have had none. The new association is designed to fill this vacancy and to be national in scope. Its motto is "Fraternalism," and the object is the uplifting of the standard of salesmanship and the general advancement of the electrical interests. The idea is that the members may strive mightily, but fairly, for business and still eat and drink as friends.

All salesmen selling electrical apparatus of whatever nature are eligible to membership and are invited to join. "Shop talk" is strictly barred at all meetings by the by-laws which have been adopted; the paramount idea is social intercourse and mutual improvement. There are to be no dues. Each new member is to pay a dollar for an emblem. Minor expenses, as printing and postage, will be paid from the profits on these emblems. A man once a member is always a member unless he resigns or changes his vocation. One general meeting is to be held each year; the first one will be held in Chicago next January during the Electrical Exposition. But at these meetings there will be no exhibit or advertising of any manufacturer's goods. This provision is, of course, essential.

It is hoped, by making the organization as simple as possible and omitting all obligations, that the association will help its members to become better salesmen and better citizens, loyal and zealous in their employers' interests and yet manly and honorable in their treatment of fellow members.

Following are the names of the officers of the new association: President, Vincent Gray, St. Louis. Vice-presidents—H. N. Remington, Peoria; A. A. Morton, Chicago; J. T. McNair, Yonkers, N. Y.; C. R. Wood, Moline, Ill.; A. L. Pond, Chicago. Secretary, George H. Erich, 218 North Court Street, Rockford, Ill.

NEW BOOK.

MAXWELL'S THEORY AND WIRELESS TELEGRAPHY. Part I, Maxwell's Theory and Hertzian Oscillations, by H. Poincaré, translated by Frederick K. Vreeland. Part II, the Principles of Wireless Telegraphy, by Frederick K. Vreeland. New York: McGraw Publishing Company, 1904. Cloth; 255 + xi pages, 8 1/4 in. by 5 3/4 in.; 145 diagrams. Price, $2.00.

The name of Poincaré is sufficient guarantee of the first part of the book, without any comments by the reviewer. The author starts with the proposition that it is a fruitless task to attempt a complete mechanical explanation of electrical phenomena in all their details; but, on the other hand, it is important to show that these phenomena obey the general laws of mechanics. He then proceeds to show how Maxwell modified the then existing electrodynamic theories, so that the principles of optics could be derived therefrom. In this exposition, the author uses mechanical analogies freely, but only to illustrate general principles; for example, the flow of conduction and displacement currents, oscillatory discharges, etc., as distinguished from the elaboration of hypothetical mechanisms for explaining the ultimate nature of the phenomena. This part of the book, which occupies nearly one-half of the volume, is written in a clear and accurate style, and is made as simple and elementary as possible. It forms a good theoretical foundation for the study of wireless telegraphy, as is intended.

The second part of the book begins with general principles, then describes some of the early experiments, then some of the later apparatus, ending with selective signaling systems. In this part the principles developed in the first part are applied to practical apparatus. On the whole the book treats the subject in a very satisfactory manner.

FOREIGN TRADE POSSIBILITIES.

(By Our Special Correspondent.)

There is every indication that the requirements for equipment in electrical lines in Mexico during the next few years, with regard to street traction, light and power plants, will be of a character well worth the careful attention of American machinery and supply houses. Now that the Mexican municipal authorities are realizing the possibilities which electricity offers, transformation of mule car lines to electric power will proceed on a scale hitherto unprecedented. Work along these lines has already been commenced and is being pushed vigorously.

It is well known that throughout Mexico, in the mining as well as the agricultural districts, the old-time mule car system has long prevailed. In a comparatively very few towns these have been supplanted by electric power, Mexico City itself, the capital setting the example, although there are yet in the Mexican metropolis many miles of mule car lines in regular operation. But as might have been expected, the results have been so satisfactory where electricity has been introduced in street car traction that every municipality in the Mexican republic where the mule car system prevails, and especially where water power is available, is clamoring for the introduction of the new and modern system of electric motive power. Nor will the Mexican people be satisfied until this transformation is accomplished, however great the undertaking.

La Electrica Company, of Guadalajara, which has obtained the concession for electric street traction in that city, will expend $3,500,000 in purchasing steel rails, copper wire, cars and equipment for a hydro-electric plant.

The Compania Electrica de Aguascalientes will also expend a large sum in the purchase of copper wire, power equipment and cars.

The municipalities of Monterey, Colima, San Luis Potosi, Morelia, Toluca, Oaxaca and Puebla have each formulated plans for raising the necessary capital to abolish the mule car and install in its stead the electric car.

The announcement is made by a Mexican Government official that a concession has been granted to Gustave A. Lilliendahl to utilize 9000 liters of water per second from the San Juan River, in the municipality of Santiago, State of Nuevo Leon. The object of the concessionaire is to produce electric power for local use or for transmission to any points which he may desire. Surveys must commence within six months, construction of the works to begin within two years and to be completed within seven years.

Albert Stein, representing the Jaqui Copper Company, of Sonora, has applied for a concession to utilize a maximum of 340,000 liters of water per minute from the Zaqui River, for the purpose of producing power by electricity.

Luis Gomez Daza, Zacatlan, Puebla, has made application for the purpose of using the waters of the River Zomatlan for electric power purposes.

The Compania Electrica de Zacatecas, which was recently formed in Zacatecas to build and operate a modern electric light and power plant, has awarded the contract to Schoendube & Mengebauer, of the City of Mexico. As the power house will be located a mile from the center of the city, three-phase current at 3000 volts has been adopted. The work of installing the plant will begin early in the coming year. The firm whose name is herewith given is a responsible one and will need much material in the way of machinery, transformers and other equipment.

OBITUARY.

MR. WILLIAM B. RANKINE, vice-president of the Niagara Falls Power Company, died on September 30 at Franconia, N. H., whither he had gone for the benefit of his health. The immediate cause of his death was congestion of the lungs, superinduced by heart trouble. To Mr. Rankine and his associate, Mr. Edward D. Adams, was due more than to anyone else the modern utilization of Niagara on a grand scale. Mr. Rankine was one of the organizers of the Niagara Falls Power Company, and at the time of his death was also interested in a number of allied concerns. He was a graduate of Union College and was a member of the University Club, the Metropolitan Club and the Bar Association. He is survived by his wife, mother and three brothers.

MR. JOHN I. SABIN died very suddenly on October 10 in San Francisco. He had not been in good health for some time and was contemplating a six months' European tour, but this trip was not planned soon enough for him to realize any benefit from it. Mr. Sabin was born in New York State on October 3, 1847. In 1864 he entered the United States Army as a telegraph operator, moving to San Francisco at the close of the War in 1876, where he became an operator for the Western Union Telegraph Company. He took an active part in organizing the Bell telephone system on the Coast in 1878, and the remarkable development of the telephone in that section of the country was largely due to his fertility of resource and combative, progressive spirit. In May, 1901, he moved to Chicago and assumed the presidency of the Chicago Telephone Company. Two years later he became identified with the Pacific States Telephone Company, for which it is claimed that Mr. Sabin secured the highest percentage of telephones to population in the United States. Mr. Sabin was one of the leaders in electrical development on the Pacific slope, being widely known in the electrical field outside of telephony.

PERSONAL.

MR. W. J. MARLAND recently moved from New York to Chicago to assume charge of the Chicago office of the Gould Storage Battery Company.

MR. O. A. STRANAHAN, who joined the Allis-Chalmers Company in December, 1904, to become manager of the power department, has been appointed sales manager. His headquarters are at Milwaukee.

MR. HENRY M. BOWEN, formerly with H. M. Byllesby & Co., of Chicago, has been made general manager of the St. Louis, Hillsboro & Southern Railroad, with offices at 415 Locust Street, St. Louis, Mo.

MR. R. G. HUNT, formerly connected with the Fort Smith Gas & Electric interests, has been made manager of the Consolidated Gas & Electric Company, of San Diego, Cal., which is conducted under Byllesby auspices.

MR. E. T. SCHATTLE, heretofore connected with the Crouse-Hinds Company, of Syracuse, has accepted a position with the Crescent Electrical Manufacturing Company, of Rochester, where he will have full charge of the engineering department.

MR. G. A. NISBET, for several years sales agent for the General Incandescent Arc Light Company, and later of the Stanley-G. I. Electric Manufacturing Company, has been appointed general manager of the Charles A. Thompson Company, New York City.

MR. F. B. HUNTINGTON, secretary of the Eastern Wisconsin Railway & Light Company, has been elected vice-president of the company to succeed Mr. T. F. Grover, who recently resigned. Mr. Huntington will continue in his office as secretary for the present also.

MR. E. H. McHENRY, fourth vice-president of the New York, New Haven & Hartford Railroad, on October 1, took charge of the engineering department of the entire New Haven system. He formerly had supervision of the engineering department of the electrical division only.

MR. H. U. BADEAU has been appointed New York representative of the Switchboard Equipment Company, of Pittsburg, with headquarters at 30 Cortlandt Street. Mr. Badeau for several years past has been with the engineering department of the Western Electric Company in New York.

MR. G. F. BROCKMAN has resigned his position as electrical engineer and superintendent of the Hydro-Electric Light & Steam Power Company, of Jackson, Ala. He was the designer and builder of this installation which has made an unusually good record, having operated every night for fourteen months without a shutdown.

MR. WARREN F. HUBLEY, recently representative of the Sunbeam Incandescent Lamp Company, at Philadelphia, Pa., has resigned in order to accept the position of western representative of the American Transformer Company, of Newark, N. J. His headquarters will be with the Western Electric Company, Chicago, Ill.

MR. CHARLES L. SEEGER is now representing the Electric Storage Battery Company, of Philadelphia, in Mexico, his office being at Primera de Humboldt No. 10, Mexico City. Associated with Mr. Seeger is Mr. W. G. Davis, who has for some time been connected with the Electric Storage Battery Company in its Philadelphia sales office.

MR. ERRETT L. CALLAHAN has resigned his position as manager of the Prometheus Electric Company, of New York, in order to take charge of the electric heating work of the General Electric Company in the Chicago territory. Mr. Callahan was also formerly connected with the Simplex Electric Heating Company as assistant manager.

MR. M. C. MILLER, formerly connected with the Westinghouse Electric & Manufacturing Company, has been appointed assistant sales manager of the Allis-Chalmers Company. Mr. Miller joined the Allis-Chalmers Company a little over a year ago, and now takes charge of all matters in the sales department which do not require the personal attention of the manager.

MR. CHARLES W. LAWRIE, for several years general superintendent of the Ball Engine Company, Erie, Pa., and consulting engineer for many of the most important high-speed engine builders of the United States, has accepted the position of general superintendent of the Reeves Engine Company, of Trenton, N. J. Mr. Lawrie assumes his new duties on November first.

MR. KENNETH B. THORNTON, recently appointed operating manager of J. G. White & Co., has been made manager of the Nassau Light & Power Company, of Roslyn, Long Island. This company is managed and operated by J. G. White & Co. Mr. Thornton, previous to his association with White & Co., was connected with the Royal Electric Company, of Montreal, and the Montreal Light, Heat & Power Company.

MR. GEORGE K. WOODWORTH, for the past four years the examiner in charge of wireless telegraphy and long-distance telephony in the Electrical Division of the U. S. Patent Office, is now associated with Mr. Alexander P. Brown, of 31 State Street, Boston, Mass., under the firm name of Brown & Woodworth, attorneys-at-law. Mr. Woodworth will make a specialty of electrical patent matters in the Patent Office and in the U. S. Courts.

MR. C. A. GREENIDGE has been promoted from the position of superintendent of the electrical department of the Utica (N. Y.) Gas & Electric Company to that of general manager of that department. Mr. William J. Cahill, who has been general manager of the gas department and secretary of the company, has retired as secretary, and Mr. M. J. Brayton, whose place at the head of the electrical department Mr. Greenidge takes, has been appointed secretary.

MR. HARRY H. HORNSBY has accepted the appointment as sales manager of the conduit department of the Sprague Electric Company, New York, succeeding Mr. Alexander Henderson. He resigned the position of chief inspector of the Department of Electricity in Chicago to become sales engineer of the conduit department of the Sprague Company, which place he has held until his present advancement. Mr. Hornsby's extensive experience in the electrical business, both East and West, has qualified him to an unusual extent for his new position.

MR. CECIL B. SMITH, formerly chief engineer of the Niagara, Lockport & Ontario Power Company, and now in the employ of the Temiskaming & Northern Ontario Railway and the Ontario Hydro-Electric Power Commission, is making a tour of Europe for the purpose of investigating electric railway equipment abroad. He will study especially the electric locomotives of Italy, Switzerland, Germany, France and England. It is the intention of the Power Commissioners to equip the new Ontario Railway with electric locomotives in the near future, and they desire to investigate the feasibilty and practicabilty of such a road under the operating conditions which prevail abroad.

MR. B. J. JONES, formerly on the staff of Sargent & Lundy, consulting engineers, of Chicago, has accepted the managership of the electrical department of the Cincinnati Gas & Electric Company. He is well qualified for his new position, having in his former capacity come closely in touch with much of the electrical work of the Cincinnati Gas & Electric Company. Mr. Jones is the inventor of the flat flexible bond and solid terminal, designed to go under the fishplate, which was sold originally as the Atkinson bond. He is also the designer of many of the details of high-tension construction used in the Indianapolis & Cincinnati Traction Company's line between Indianapolis and Rushville, and adopted by the Westinghouse Electric & Manufacturing Company as standard construction for certain classes of single-phase trolley work. Previous to his connection with Sargent & Lundy, Mr. Jones was superintendent of the South Chicago City Railway Company, which position he accepted upon leaving a similar one at Sioux City, Iowa. He was also at one time with the Westinghouse Electric & Manufacturing Company.

MR. W. T. McCASKEY has joined the forces of the Allis-Chalmers Company and will act as a special representative where contracts are being considered for such work as the equipping of in-

terurban railroads, hydro-electric projects, etc. Mr. McCaskey was born in Richmond County, Wis., in 1863. His experience in electrical work began in 1882 as manager of the plant of the Eau Claire Electric Light & Power Company. Later he was connected with the Sperry Associate Electric Company, of Kansas City, Mo., and he operated the first electric lighting plant in Fort Worth, Texas, in 1885. From 1889 to 1894 he represented Edison and other interests on the Pacific Coast. He afterwards acted as representative of the Standard Electric Company, in Chicago, going to Buenos Ayres, South America, in 1899, for the Westinghouse Electric & Manufacturing Company and Agar, Cross & Co., where he remained until 1901. He was then Director in Spain and Portugal for the Societe Anonyme Westinghouse until December, 1903, and manager for Agar, Cross & Co., until May of this year. Mr. McCaskey will have his headquarters in Milwaukee.

TRADE PUBLICATIONS.

WIRING RECEPTACLE. Flyer No. 2166, illustrating a porcelain receptacle for moulding wiring brought out by the General Electric Company.

STORAGE BATTERIES. A small folder illustrating storage batteries for railway signal service brought out by The Westinghouse Machine Company.

TRANSFORMER FOR THAWING PIPES. The American Transformer Company issues this little pamphlet, illustrating and describing its transformer thawing outfits.

TRANSFORMERS. A price list and proposal form of standard lighting and power transformers, manufactured by the Pittsburg Transformer Company, Pittsburg, Pa., in sizes from .6 to 50 kilowatts.

TRANSFORMERS. This is bulletin No. 33 of the American Transformer Company, in which are illustrated and described the various types of high-voltage transformer manufactured by the company.

COMMON-BATTERY SWITCHBOARDS.—Folder No. 8 illustrating and describing the No. 2 Type of common-battery switchboard and its accessories, manufactured by The Dean Electric Company, Elyria, Ohio.

TELEPHONE CABLE. A booklet issued by the Stromberg-Carlson Telephone Manufacturing Company, Rochester, N. Y., illustrating and describing the essential features of the line of telephone cable manufactured by the company.

MULTIPLE ENCLOSED ARC LAMPS. Supply catalogue No. 7591, illustrating and describing the parts of the edgewise parallel-rod, 110-volt, direct-current multiple enclosed arc lamp, forms 14 and 12, manufactured by the General Electric Company.

COMMON-BATTERY DESK TELEPHONES. A booklet entitled the "Brownie Bulletin," and containing a parody on "The House That Jack Built," the new type of desk stand manufactured by the Kellogg Switchboard & Supply Company being substituted for Jack's house.

CORLISS ENGINES. A catalogue of handsome design, published by The C. & G. Cooper Company, Mount Vernon, Ohio, and containing full-page illustrations made from photographs of representative plants in operation, which give an idea of the general design of the Cooper-Corliss engine.

INSULATORS. Supplement No. 1 to The Insulator Book which is issued by the Locke Insulator Manufacturing Company, Victor, N. Y. The supplement contains revisions and additions to the catalogue and is accompanied by an addenda sheet to be pasted in The Insulator Book.

HEATING APPARATUS. Catalogue No. 186 illustrating and describing "A B C" heating apparatus for the heating and ventilating of factory and public buildings and the drying of materials of all kinds. This apparatus is the product of the American Blower Company, Detroit, Mich.

BLACK AIR-DRYING VARNISH. This is a small pamphlet exploiting the Sterling black air-drying varnish manufactured by The Sterling Varnish Company, Pittsburg, Pa. The pamphlet also contains a list of other Sterling insulating compounds, together with a table of comparison of thermometrical scales.

MINING MACHINERY. A handsome catalogue issued by The Jeffrey Manufacturing Company and designated Bulletin No. 10, in which are illustrated and described the numerous types of electric mine locomotives manufactured by this company, together with their application to various uses and conditions.

RAILWAY LINE MATERIAL AND RAIL BONDS. A handsome, well-executed catalogue, No. 1049, from the General Electric Company, presenting a new list of railway line material devices manufactured by this company. The list comprises the numerous appliances required in railway line construction work.

THE JONES STOKER. A pocket edition catalogue illustrating and describing very fully the Jones under-feed mechanical stoker, of which The Under-Feed Stoker Company of America, Chicago, Ill., is the sole manufacturer. The catalogue also contains illustrations showing the method of equipping various types of boilers with the Jones stoker.

ELECTRICAL SUPPLIES. This is a general supply loose-leaf catalogue, in a substantial cloth binder, issued by the Commercial Electrical Supply Company, St. Louis, Mo. Accompanying the catalogue is a paper-bound price list and discount sheet. The catalogue covers fully the very complete line of electrical supplies of all kinds carried by the company.

ROTARY CONVERTERS. This is special publication No. 7038 from the Westinghouse Electric & Manufacturing Company, treating of Westinghouse rotary converters, their characteristics and construction, together with instructions for their erection, operation and care. The catalogue is fully illustrated and contains several diagrams of connections also.

MOTORS. Booklet No. 4120, containing illustrations and brief descriptions of automatic single-phase induction motors ranging in size from 1/40 to 1/2 horse-power, and bipolar and multipolar enclosed direct-current motors in sizes from 1/20 to 2 1/2 horse-power. These little machines are manufactured by The Emerson Electric Manufacturing Company, St. Louis, Mo.

SWITCHBOARDS FOR SMALL DIRECT-CURRENT PLANTS. Bulletin No. 409, containing illustrations, descriptions and price lists of switchboards for small direct-current plants, ranging in size from 5 to 20 kilowatts at 125 volts or from 10 to 40 kilowatts at 250 volts. The switchboards are manufactured by the Stanley-G. I. Electric Manufacturing Company.

PAISTE SPECIALTIES. Catalogue No. 12, illustrating and briefly describing the line of electric light supplies manufactured by H. T. Paiste Company, Philadelphia, Pa. The catalogue is conveniently compact and substantially bound in red cloth. The illustrative and descriptive matter includes the company's various types of sockets, receptacles, switches, rosettes, cut outs, socket fittings, etc.

INTERCOMMUNICATING TELEPHONES. Bulletin No. 13, illustrating and describing the various types of intercommunicating telephones, manufactured by the Stromberg-Carlson Telephone Manufacturing Company, Rochester, N. Y. The bulletin deals exclusively with the central energy system with metallic circuits, and besides showing various types of apparatus, contains several representative diagrams of connections.

HARMONIC PARTY LINE SYSTEMS. This is bulletin No. 100, issued by The Dean Electric Company, Elyria, Ohio, which comprises a reprint of an article entitled "Concerning Harmonic Party Line Systems," by W. W. Dean, vice-president and chief engineer of The Dean Electric Company. The bulletin is well illustrated and the last five pages are devoted to the exploitation of the harmonic system manufactured by this company.

TABLES. These convenient tables are issued from time to time by the Warren Electric Manufacturing Company, Sandusky, Ohio, and are printed on cards of pocket size, the reverse sides of which bear illustrations of representative products of the company. Tables 11 and 12 give allowable pressures for steam boilers constructed of 1/4-inch single and double riveted plates respectively, while Table 17 gives an all-night street lighting schedule for the month of November.

CAR HEATING AND LIGHTING APPARATUS. A very complete catalogue of large size, containing illustrations and descriptions of the Gold Car Heating & Lighting Company's (New York) improved heating and lighting apparatus for steam and electric railways. The book also contains illustrations and descriptions of other railway supplies and gives numerous diagrams of the various heater equipments to meet different requirements. The catalogue is issued in two editions, one bound in red paper and the other in brown cloth.

BUSINESS NEWS.

THE IDEAL STOKER, 114 Liberty Street, New York, has secured the contract for installing Ideal stokers at the Bayonne (N. J.) works of the Para Recovery Company.

THE MOLONEY ELECTRIC COMPANY, St. Louis, Mo., will hereafter be represented in the East by The Electro-Dynamic Company, 11 Pine Street, New York City.

H. T. PAISTE COMPANY, Philadelphia, Pa., announces the opening of an office in Boston at 7 Otis Street, Winthrop Square. This office will be in charge of Mr. Frank Booth, who will also represent the New York Insulated Wire Company in that city.

C. H. M'GIEHAN COMPANY, automatic and special machinery experts, of No. 11 Broadway, New York, are distributing to their clientele a paper-mounted thermometer, on either side of which is printed a column of decimal equivalents, although the souvenir may be had without this.

CHANDLER & TAYLOR COMPANY, Indianapolis, Ind., reports the recent sale of one of its standard service enclosed self-oiling engines of the direct-connected type to the owners of the New York Life Building, Chicago, Ill.; also one of the same type, but made tandem-compound, to the University of Nebraska, at Lincoln, Neb.

BAY STATE LAMP COMPANY, of Danvers, Mass., is directing attention to the excellence of the renewed incandescent lamps manufactured by the company. The sale of these lamps is said to be increasing rapidly in spite of deep-rooted predjudice against renewed lamps. The company is making a liberal proposition to users of incandescent lamps who desire to make a fair trial of its product.

THE STANDARD ELECTRICAL MANUFACTURING COMPANY, Niles, Ohio, is distributing to its patrons a paper fac-simile of a pumpkin, bearing the features of a face, which may be converted into a Halloween lantern by hanging it over an incandescent electric lamp. On the inside of the sheet are some humorous lines in parody of James Whitcomb Riley's "When the Frost Is on the Punkin."

MACHADO & ROLLER, 203 Broadway, New York, selling agents for the Whitney Electrical Instrument Company, state that hereafter any recalibration, re-adjustment or repair of instruments that may be required within a period of one year after their sale will be effected by the company gratis, provided the instrument is returned prepaid with the seals intact. A paster to that effect is placed on each instrument.

THE SCHMIDT-WILCKES ELECTRIC COMPANY, 522 Gregory Avenue, Weehawken, N. J., announces that it has completed its organization as an independent telephone and switchboard manufacturer, with its plant located at Weehawken and offices at 135 William Street, New York City. The company has secured valuable telephone patents, under which its new product will be manufactured.

THE HOLOPHANE GLASS COMPANY, New York, was awarded the contract for the lighting fixtures in the new million-dollar court house at Syracuse, N. Y., perhaps the finest of its kind in the country. The new Holophane-Pagoda ball was adopted as a standard in 6-in., 7-in. and 8-in.

sizes, 900 of these being used on the decorative chandeliers. Over 2,000 Pagoda reflectors are to be employed for what is termed "the useful light" fixtures throughout the building.

THE COLONIAL FAN & MOTOR COMPANY, Warren, Ohio, reports the recent installation of twenty-five motors for The H. J. Heinz Company, of Pittsburg, Pa., for individual driving of can machinery and printing presses; also nineteen motors for the Kinnear Pressed Radiator Company, of West Pittsburg. Fourteen large motors have just been shipped to the Independent Packing Company and the Chouteau Avenue Ice & Cold Storage Company, of St. Louis, Mo.

THE ONEIDA COMMUNITY, LTD., Oneida, N. Y., is putting on the market a special chain for rasing and lowering arc lamps suspended from mast arms. The chain is made in various sizes to fit any pattern of pulleys and will, it is claimed, out-wear two or three times over any other attachment which has yet been put on the market for this purpose. We understand that the Oneida Community, Ltd., is prepared to send a sample complete, ready to put on an arc light, to any central station who will apply for same.

G. M. GEST, subway contractor of New York and Cincinnati, has been awarded a contract for the construction of a complete electrical subway system for the Dayton Lighting Company, Dayton, Ohio. This plant has recently been acquired by new interests, who are rebuilding and reequipping the whole plant. The contract given to Mr. Gest is for subway installation for the whole city, covering twenty miles of streets and involving over a million feet of conduit. The system is to be absolutely modern and up to date, and will cost in the neighborhood of $250,000.

STROMBERG-CARLSON TELEPHONE MANUFACTURING COMPANY, Rochester, N. Y., reports having closed contracts for switchboards for the following places: Roxboro, N. C.; Onaga, Kan.; Rochester, N. Y.; Ellicottville, N. Y.; Eldorado, Ark.; Wabash, Ind.; Newark Valley, N. Y.; Camden, N. J.; Sonora, Ky.; Minneapolis, Minn.; Pattersonville, N. Y.; Des Moines, Ia.; Seward, Ill.; Sublette, Ill.; Little Valley, N. Y.; Beloit, Kan.; Milbank, S. D.; Wheeling, W. Va.; Linn Grove, Ind.; Brooton, Minn.; Abbott, Tex.; Vertrees, Ky.; Payette, Ida.; Hammonton, N. J.; Chenoa, Ill.; Tiskilwa, Ill.; Swedenboro, N. J.

THE BALL & WOOD COMPANY, steam engine builders, 17 Battery Place, New York, has recently added to its works at Elizabethport a plant for turning out welded flanged pipe and pipe bending. The company will do no pipe fitting and undertake no piping contracts, but is prepared to quote prices and fill orders for the material used in this work. In its new plant The Ball & Wood Company has endeavored to avail itself of the latest improvements in every line of equipment, not only in making the joints and bends, but in handling the material. To distinguish it from others on the market, the company has given its trade name, "Ballwood," to this joint.

WILLIAM ROCHE DRY BATTERY COMPANY is the name of the firm, recently incorporated with a capital of $25,000, which succeeds to the business conducted by William Roche, since 1897, at 52 and 54 Park Place, New York City. Mr. Roche is president of the new corporation, and has associated with him Messrs. C. Laton Ford, formerly first vice-president of the Celadon Roofing Tile Company, New York; Mr. Ernest A. Lowe, president of The Lowe Electric Company, and William C. Hubbard, for a number of years with the Westinghouse Electric & Manufacturing Company. Mr. Lowe is vice-president, Mr. Ford treasurer, and Mr. Hubbard secretary of the company.

THE NEW PROCESS RAWHIDE COMPANY, Syracuse, N. Y., has announced its intention of going more extensively into the manufacture of metal gears of all kinds, as well as its well-known "New Process" noiseless pinions. For this purpose the company has just completed a two-story brick addition, containing about 10,000 feet of floor space, and is installing a number of additional turret lathes, drills, grinders, spur gear cutters, bevel gear planers, and other machines necessary for the manufacture of accurate gearing. This additional equipment will increase the company's capacity about 75 per cent. Its business is reported as very brisk, shipments being already considerably in excess of last year.

THE WESTINGHOUSE MACHINE COMPANY notes an increasing demand for the gas engine, and has received within the last few weeks orders for these machines ranging from 10 to 1,000 b.h.p.; the orders include thirty-six engines, aggregating 6,647 b.h.p. The company has also received from the Public Lighting Commission of the City of Detroit, Mich., orders for two 2,000-kw. turbine-type generator units for installation in its power house on the river front in the center of the business district of the city. Three large orders for Roney mechanical stokers have recently been placed with the company, one from the Jones & Laughlin Steel Company, of Pittsburg, one from the Lehigh Valley Traction Company, of Philadelphia, and another from the Pressed Steel Car Company, of Pittsburg, besides one from the Pennsylvania Railroad Company for its shops at Altoona, and numerous smaller orders from various parts of the country.

THE PELTON WATER WHEEL COMPANY, San Francisco, Cal., states that owing to the steady growth of its business it is obliged to enlarge its works, and to that end has purchased a block of land in South San Francisco, where a modern machine shop is now under course of construction. This new shop will be equipped with the latest high-grade tools and handling devices, affording exceptional facilities for the construction of high-grade apparatus. The company recently closed a contract with the Oro Water, Light & Power Company, Oroville, Cal., for two complete Pelton units of 2,000 horse-power each, direct-connected to electric generators, the wheels operating under a 465-ft. head. Among other recent orders are: A wheel equipment for the Crown Columbia Paper & Pulp Company, of Washington, consisting of a triple Pelton unit for direct-connection to heavy pulp grinders; a 300-h.p. unit for Takata & Co., of Tokio, and a large wheel for the Ingersoll-Sergeant Drill Company for direct connection to one of their compressors.

CENTRAL STATION NEWS

Readers are cordially invited to contribute to this department items of news relating to plants in their vicinity.

ALABAMA.

COURTLAND.—It is reported that Lawson, Sykes & Co. want prices on machinery and equipment for an electric light plant.

ARIZONA.

BENSON.—It is proposed to organize a company under the name of Benson Light & Water Company, with a capital of $5,000. Doan Merrill is interested.

CLIFTON.—The two large mining camps of Clifton and Morenci, Arizona, are to have electric power to operate both smelters. The Caledonian Coal Company, Gallup, New Mexico, owners of the smelters, is preparing to undertake the project.

ARKANSAS.

LITTLE ROCK.—Springdale has granted a franchise for an electric light plant to Spencer Owen of Belgrade, Neb.

ARGENTA.—C. J. Humphreys and others have been appointed a committee to select a site for the new electric light plant, to be erected by the municipality.

MENA.—The Mena Light, Heat & Power Company has been incorporated with a capital of $250,000, to own and operate a heating and lighting plant, in addition to cold storage and other utilities. Incorporators: Francis R. Hoyt, Willston D. Hoyt, and others.

VAN BUREN.—The Van Buren Electric Light & Power Company has been incorporated with a capital of $25,000. The incorporators are John E. Powers, Henry L. Fitshugh and Sydney A. Pernot. The company will operate a plant to furnish electric lights in this city.

CALIFORNIA.

AUBURN.—At a meeting of the city trustees it was decided to sell the old gasoline street lights and install electric arc lights.

DOWNIEVILLE.—W. Dubuque has purchased the interest of Tony Costa in the local electric light plant.

SACRAMENTO, E. J. Carragher, it is reported, is clerk of a committee appointed to find ways and means of establishing a municipal lighting plant.

OAKLAND.—The Northern Water Power Company has been incorporated by H. L. Atkinson, Charles P. Pritchard and others of Oakland, with a capital stock of $5,000,000.

MAYFIELD.—The municipal electric light system has been abandoned and the town trustees have contracted with the Redwood City Electric Company to furnish power for street illumination.

SAN FRANCISCO.—The West Coast Electric Light & Power Company has been incorporated with a capital stock of $25,000 by J. F. Hathaway, T. F. Fogelsang, C. R. Lundberg, W. T. Hume and C. Ulmer.

LOS ANGELES.—The Pacific Light & Power Company is preparing to develop electric power in Yavapai County, Ariz. The initial installation will consist of a 1,200-h.p. hydro-electric plant, which it is expected will be increased to 6,000 horse-power eventually.

SAN FRANCISCO.—The Union Power & Light Company has been incorporated with a capital of $2,000,000. Directors: John Martin, M. Fleishhacker, R. E. Wallace and H. A. Cook, of San Francisco; Frank H. Brack, of Vacaville; John Humphrey and R. Kirman, of Reno.

LOS ANGELES.—The Valley Electric Company has been incorporated by R. F. Davis, E. A. Miller and A. Morris of Los Angeles, and T. D. Allin and E. Galbraith of Pasadena. The organizers of the company had already secured an electric lighting plant at Santa Maria, Cal., and the company was organized to take over and operate this property.

SAN FRANCISCO.—The California Gas & Electric Corporation recently gave to John Martin & Co. two orders of 7-strand aluminum cables, aggregating 150,000 lbs., for use on its extensions. An additional 45-mile, three-phase transmission line will be built between San Francisco and San Jose. Six-naught cable, of 350,000 circ. mils will be used. The other order, consisting of No. 1 aluminum, will be used on a new branch transmission line, tieing in near San Jose and extending 40 miles to the cement works of the Santa Cruz Portland Cement Company's new plant at Davenport, Santa Cruz County. Power will be supplied for the manufacture of about 5,000 barrels of cement per day. The company is also installing one of the three frequency-changers, which are to be located in the new gas engine reserve plant, near San Francisco. It is the intention to start up the new frequency-changer in November and deliver current to the railways so that the engines can be shut down in the Eleventh and Bryant Street power station, which is being converted into a sub-station.

SAN FRANCISCO.—The Nevada Power, Mining & Milling Co.'s electric power plant on Bishop Creek, Inyo County, Cal., has gone into commission after making a good record for construction. One of the two 750-kw., three-phase National

Electric generators of the initial installation is in successful operation, supplying lights in Tonopah and Goldfield, Nev. The second generator is being installed. A Pelton water wheel, operated under a head of 1,064 ft., is direct connected to each generator. The transmission line extends 85 miles to the junction at Alkali Springs, where it branches, the distance thence to Tonopah being 18 miles, and to Goldfield, 10 miles. An elevation of 10,000 feet is reached in crossing the White Mountains. An additional Bullock generator, of 1,500 kilowatts capacity, will be delivered by the Allis-Chalmers Company about December 1 and connected to a Pelton water wheel. The home office of the company is in Denver, Col.

YREKA.—Since the consolidation of the Siskiyou and Yreka electric light and power plants, many changes have been made, with more contemplated for greater capacity. At present the old Yreka plant at Shasta River, will be used for lighting purposes in supplying Yreka, Fort Jones, Greenview, Etna, etc., while the Siskiyou plant at Fall Creek, Klamath River, will supply all the power used and the lights at a number of places in Shasta Valley, and be taxed with 400 horse-power for the operation of the Montague box factory and the Yreka Creek dredger. A couple of large transformers have been sent over to Humbug, where about 40 horse-power will be used for the new Mono quartz mill. The Siskiyou Company is also putting in a large new dynamo at Fall Creek, which will increase the capacity of that plant from 700 to 2,000 horse-power, and there is 400 horse-power at the Shasta River plant, which makes a capacity of 2,400 horse-power. When the new dynamo is installed the two plants will be joined for supplying both systems, with expectation of extending wires to all other sections of the country, where needed.

SAN FRANCISCO.—The Northern Water & Power Company has been formed by H. L. Atkinson, C. P. Pritchard, T. A. Allan and others; the capital is $5,000,000.

SANTA MARIA.—The Isaac Springer Investment Company, of Los Angeles, has purchased the Santa Maria Light & Power Company, and contemplates extending its lines to Guadulupe.

SAN FRANCISCO.—The General Electric Power Company, of San Franicsco, has been incorporated with a capital stock of $1,000,000, by J. P. Lucey, W. E. Cashman, W. T. Love and K. J. C. Seymour and Guy C. Calden.

COLORADO.

ROCKVALE.—The Council is reported to have granted the Arkansas Valley Electric Light Company a franchise to construct and operate an electric light plant.

GREELEY.—The Home Electric Light & Power Company will increase its capitalization from $4,500 to $50,000. The company, which is composed of professors in the State Normal School, and others, has conducted a small electric light plant in the vicinity of the State Normal School so successfully that it will enlarge the plant to supply the entire town. A franchise was granted to it recently.

DENVER.—It is stated that improvements costing nearly $1,000,000 are to be made by the Denver Gas & Electric Company to its plant during the coming year. Next spring in the plant at Sixth and Lawrence streets a new Curtis 3,000-kw. turbine is to be installed. Later on in the year a similar turbine is to be installed in this plant. New machinery costing about $150,000 to replace worn-out apparatus is to be purchased by the company. The building is to be enlarged at a cost of about $45,000. Four 500-h.p. boilers are to be installed.

DELAWARE.

WILMINGTON.—An electric light line will be run from New Castle to Delaware City to furnish light to the latter place.

FLORIDA.

MAYO.—The Town Council has granted Clarence H. Ellis and associates a franchise for the construction of an electric light plant and water works.

KEY WEST.—An ordinance is stated to have passed first reading, granting to Messrs. Ladd, Larkins and Jerguson, a franchise to furnish electric light to Key West.

GEORGIA.

COLUMBUS.—The City Council, it is stated, is considering the cost of a municipal electric light plant.

ROCKMART.—B. Stark, City Clk., writes that it is proposed to construct an electric light plant to cost about $7,000.

COCHRAN.—Bids for the purchase of $17,000 electric light and water bonds are wanted at once. Address Dr. T. D. Walker, chairman of the bond commissioners.

OCILLA.—The Mayor and Board of Aldermen are stated to have awarded to Engineer J. B. McCrary, of Senora, the contract for water works and an electric light system, to cost about $28,000.

MONTICELLO.—The town of Monticello has bought the electric light plant, the property of B. Jordan, and will operate it in connection with the water works system, using electric power for pumping the water. The two plants will be operated together.

LAWRENCEVILLE.—J. W. Chapman, of Lawrenceville, has secured an option on a water-power near Brevard, N. C., and proposes to develop the same, and will build an electric light plant to supply the town of Brevard, and the Transylvania Railroad.

IDAHO.

RATHDRUM.—The Rathdrum Light & Power Company has been reorganized and will hereafter be known as the Rathdrum Electric Company. The ownership is the same as before.

LEWISTON.—The Clearwater Irrigation, Land & Boom Company has been incorporated with a capital of $150,000, by H. L. Pittock and F. W. Leadbetter, of Portland, Ore., and L. A. Porter, of Lewiston.

ILLINOIS.

STREATOR.—The city of Streator is talking of putting in a public electric light plant.

NASHVILLE.—K. K. Steinhauser has purchased the Nashville electric light plant from the former owners.

HILLSBORO.—Hillsboro Electric Light & Power Company, has increased its capital stock from $5,000 to $50,000.

PLANO.—The Plano Heat, Light & Power plant is now the property of E. J. Kreis, of Mendota, and E. Lindner, of Milford, Ill.

DEPUE.—The village of Depue is to have an electric lighting plant. A franchise for this purpose was granted at a recent meeting of the town board.

FREEBURG.—Plans and specifications have been completed by Owen Ford, of St. Louis, Mo., for the proposed municipal electric light and power plant, to cost about $9,000. Charles Keessler is village clerk.

BREESE.—The Breese Water & Light Company is preparing to install a central lighting plant. William H. Bryan, Lincoln Trust Building, St. Louis, Mo., is the consulting engineer in charge of the work.

SALEM.—The village board of Odin has granted a twenty-year franchise to the Odin Coal Company, for the operation of an electric light plant, and the village has contracted for forty arc lights for street lighting at $50 each.

FISHER.—The Fisher village board of trustees has awarded to the Wardlow Electric Lighting Company a franchise, which provides that the company shall light the streets of the village with twelve arc lights of 1,200 candle-power each at $50 a month.

ROCKFORD.—At a meeting of the stockholders of the Central Heat & Power Company at the company offices it was decided to double the capacity of the lighting plant, and the directors of the company were empowered to at once open negotiations for the purchase of a new 500-h.p. engine and generator.

CHICAGO.—John H. Radford is preparing plans for an addition to an electric light plant at Fifty-eighth street and Cottage Grove avenue, Washington Park, for the south park commissioners, who will take figures when the plans are ready. It will be one story, of brick and stone, with slate roof. The commissioners expect within two or three years to build a central electric light plant with sufficient capacity to light the entire park system. It will cost about $200,000. D. H. Burnham & Co. are the architects.

MOUNT VERNON.—A largely attended meeting was held Oct. 2, to take action on the increased scale of charges made by the Citizens' Gas, Electric & Heating Company, for its utilities, the company having refused to adopt the scale of charges recently made by Ordinance of the City Council, which had come to the rescue of the people. The people will tender the old scale of charges. A committee of citizens has been appointed to represent the public and to defend any suit brought by the company, and public supscriptions will be taken up to pay counsel in case of litigation.

INDIANA.

CRAWFORDSVILLE.—J. F. Davies, of Toledo, Ohio, has secured the contract for repairing the city electric light plant at $7,433.

GREENWOOD.—The Citizens' Water & Light Company has been incorporated with $25,000 capital stock. The directors are David E. Demott, John W. Henderson and James A. Craig.

WEST TERRE HAUTE.—The town trustees have granted the West Terre Haute Light & Power Company a franchise to construct and operate an electric light plant. Claude Erwin is one of the incorporators.

SHELBYVILLE.—The Shelbyville Water & Electric Light Company's plant has been purchased at receiver's sale by C. F. Street, of New York, the consideration being $36,000. Mr. Street will at once improve the property, retaining Mr. F. M. Nichols as superintendent.

SCOTTSBURG.—The City Council has granted a franchise to James Smith for an electric light plant and a franchise to Joseph Shea for a water works plant. Messrs. Shea and Smith will join their franchises and put up one plant that will furnish electric light and water instead of having two separate plants, and work will begin on the building as soon as plans can be perfected and the contract let.

HUNTINGTON.—The Huntington Light & Fuel Company is installing two 200-kw., 60-cycle, 2,300-volt General Electric generators and switchboard to replace its 125-cycle, 1,040-volt apparatus. The company will furnish current to the Erie Railroad for light and power in the shops at Huntington. The company has also just closed a contract to supply steam for heating the court house now being erected at Huntington.

INDIAN TERRITORY.

ATOKA.—The Atoka Light & Power Company will spend about $10,000 in improvements, it is said.

HOLDENVILLE.—The Chas. DeWatteville Electric Light & Ice plant, valued at $25,000, was destroyed by fire. The plant will be rebuilt without delay.

VINITA.—The power plant of the Vinita Electric Light, Ice & Power Company is reported to have been destroyed by fire on Sept. 26, with a loss of $5,000.

MUSKOGEE.—G. W. Sargent, of Joplin, Mo., is stated to have petitioned for permission to construct a power plant to replace the one recently destroyed by fire.

IOWA.

DES MOINES.—Dayton Heat & Light Company has been incorporated with a capital of $10,000.

SPIRIT LAKE.—The proposition to sell the municipal electric light plant was defeated at a special election.

FORT MADISON.—Several thousand dollars' worth of new machinery is being installed in the electric light plant here.

AFTON.—The Council is reported to be considering the question of constructing a municipal electric light plant, or of granting a franchise for the plant.

CHARLES CITY.—The electric lighting plant has been sold by H. V. Russell & Co., to F. O.

Martin, of Floyd, and A. L. Dodd. A number of extensive improvements are planned.

WEBSTER.—Mr. R. B. Leroy, in behalf of outside capitalists, has offered the city of Webster $100,000 for the municipal water, heat, light and gas plants and a street car franchise.

KANSAS.

PAOLA.—By a close vote this city has voted $25,000 in bonds for the building of a municipal electric light plant.

MINERAL.—The Sun's Rays Electrical Company has asked for a franchise to install an electric light plant here.

CHAPMAN.—The Chapman Milling, Elevator & Electric Light Company has been incorporated with a capital of $30,000.

MENA.—The Mena Light, Heat & Power Company has been incorporated with a capital of $250,000 by Francis R. Hoyt and others.

OSBORNE.—Frank A. Higley, of Cummings, Kan., has asked the City Council for an electric light franchise, and proposes to put in a lighting plant here if given a free site for his power house.

GARNETT.—The Garnett electric light plant has changed hands and is now owned by Dr. Milligan, J. Stevenson, J. F. Delinger, C. H. Rice, P. E. Keeney, J. W. Bronston and Leper Adams. J. F. Delinger is president of the company, J. W. Bronston, secretary, and J. H. Stevenson, treasurer and manager

KENTUCKY.

PIKEVILLE.—The Pikeville Electric Light Company has been incorporated with a capital of $50,000 to operate an electric light plant.

HOPKINSVILLE.—John H. Bell, Jr., of Hopkinsville, is stated to have secured a franchise for the construction and operation of an electric railway and electric light plant.

MOUNT STERLING.—Cincinnati capitalists have closed a contract with J. W. Riley, of Morehead, to erect a modern electric light plant in that city at once. The plant will cost $15,000.

WILLIAMSBURG.—Gleaves & Company, of Lynchburg, Va., propose to construct and own water works and an electric light plant at Williamsburg, to cost about $45,000. J. A. Gilman is the engineer.

COVINGTON.—The National Construction Supply Company, of St. Louis, Mo., has submitted to the light committee of the General Council a proposition to install an electric light plant, with duplicate machinery of sufficient capacity to supply 400 arc lights of 2,000 candle-power and 2,000 incandescent lights, for $75,000.

LOUISIANA.

NEW ORLEANS.—Work on the Consumers' Electric Company's new plant is progressing rapidly.

CHARLES CITY.—Martin & Dodd have purchased the electric light plant, and will put in a heating plant.

MAINE.

DEXTER.—The Dexter Electric Light Company has sold its plant and business to N. Curtis Fletcher, of Boston.

LEWISTON.—The Lewiston & Auburn Electric Light Company will make a further reduction in rates to all its customers, upon meter service. The reduction is from 10 cents per kilowatt-hour to 9 cents per kilowatt-hour.

PORTLAND.—The International Paper Company has brought a bill in equity in the United States Circuit Court here against the Bodwell Water Power Company of Old Town, asking the court to restrain the latter company from erecting and maintaining dams on the Penobscot River and the Stillwater branch.

ELLSWORTH.—The City Council has taken action which will enable a company of which W. H. Buhlen, of Boston, Mass., is the head, to build a dam across Union River. The company proposes furnishing power to the industries of Ellsworth, Bar Harbor and vicinity. The probable cost of the proposed plant is $1,000,000.

EASTPORT.—The Copen Light & Power Company has been organized at Eastport, for the purpose of generating and supplying gas and electricity for lighting, heating and mechanical purposes in Perry, Pembroke and Dennysville, in Washington County, Maine, with $10,000 capital stock. The officers are: President, Chas. E. Copen, of Eastport; treasurer, Charles H. Emery, of Eastport.

BUCKSPORT.—There are rumored plans for the development of an electric power plant at Orland upper falls. Recently an expert has been making estimates of the extent of the power, the storage of water, the size of the watershed, the annual rainfall, etc., and the result of these will no doubt warrant the expenditure of many thousands of dollars in the construction of dams, acquirement of flowage rights, purchase of real estate, besides the construction of buildings, installation of machinery, etc.

MARYLAND.

MIDLAND.—The Consolidated Coal Company, it is stated, will erect a plant at Ocean Mine, No. 1, with power enough to supply light to the town of Midland and surrounding places.

ROCKVILLE.—At a special meeting of the mayor and council of Rockville a contract was entered into with Anderson Offutt, H. Worthington Talbott and David M. Munro for the rehabilitation of the lighting plant.

BALTIMORE.—Subway Engineer Phelps will start at once the construction of a conduit line to Westport to connect with the power house of the United Electric Light & Power Company. The line will be about 11,000 feet long and will be laid in South Fremont avenue and Ridgeley street.

MASSACHUSETTS.

SOUTH HANSON.—A new company will soon be incorporated in this town, known as the Hanson Gas & Electric Company, with W. E. Damon as president.

SOUTH HADLEY.—The Holyoke Water Power Company, of Holyoke, has petitioned the selectmen of South Hadley for permission to erect poles and string wires from Holyoke to South Hadley Center.

MEDWAY.—The Kendall Construction Company, of Boston, has been awarded the contract by the Medway Electric Light & Power Company to entirely reconstruct its street and commercial lighting systems in this city.

BOSTON.—At the annual meeting of the Edison Electric Illuminating Company, of Boston, held on October 10, one of the matters considered was the sale of the Milton plant, acquired when the property of the old lighting company in that town was absorbed. The plant is no longer needed, electricity being furnished from the South Boston plant. The company's management also asked for authority to finance some of its undertakings by the borrowing of money secured by a short-time mortgage on real estate held by the company. The company has just taken title, in accordance with prior agreement, to the property in Head Place, off Boylston street, which it has occupied since starting in business. Upward of $300,000 is involved in the deal. Last July the company acquired adjacent property out to Boylston street, and changes are contemplated therein which will make of the several parcels a compact and commodious central structure for display headquarters and for offices of the company.

MICHIGAN.

DETROIT.—The Detroit Edison Company has acquired the Grosse-Pointe Farms electric lighting plant, which supplies a suburb of Detroit.

LANSING.—The Piatt Power Company, of Lansing, has purchased the water privilege at Grand Ledge and will erect a power house there.

L'ANSE.—The plans of Liebert & MacNeil, of Calumet, are stated to have been accepted for the municipal electric light plant; probable cost, $10,000.

DETROIT.—The National Gas, Electric Light & Power Company is negotiating for the purchase of the Niles Gas Company's plant and the one at Warsaw, Ind.

SOUTH LYON.—The village of South Lyon has bought the electric light building and equipment of J. R. Blackwood, and will run its own lighting system hereafter.

MONROE.—The Monroe Council has appropriated $5,000 for the rewiring of the city and for installing electric meters. This is the first step toward improving the municipal lighting plant. The River Raisin will furnish the necessary power.

HOUGHTON.—The Great Northern Power Company will have its plant and equipment installed to furnish electrical power to the mines of the Mesaba range by the fall of 1906. A number of the mines have signified their intention to utilize electric power wherever possible.

ELK RAPIDS.—Arthur McMillan, of Toledo, has been granted a franchise for a commercial lighting plant in Elk Rapids. The village is to have not less than 25 arc lights at $75 per light, and above 25 lights the charge is to be $70 per light, on a moonlight and two o'clock schedule.

MINNESOTA.

MINNEAPOLIS.—An electric light plant will be established at Mahnomen.

BELLE PLAINE.—It is stated that the Council has voted to install a municipal light plant.

FANNING.—An electric light plant and waterworks are to be established in this city in the near future.

BLUE EARTH.—W. S. Belt has succeeded F. A. Ross as superintendent of the Blue Earth electric light plant.

BEMIDJI.—The Warfield Electric Company has installed a 24-hour service at Bemidji, and is furnishing an electric service for power to its patrons.

ELLENDALE.—The Ellendale Milling & Light Company has been organized and will build a mill and electric light plant there. Frank Kycek is president and H. L. Dodge secretary.

LE ROY.—It is reported that the electric light plant, recently destroyed by fire, will not be rebuilt until spring, but a dynamo will be installed in the mill to furnish electricity for the present.

ST. CLOUD.—Samuel S. Chute, with four assistant engineers, is reported to have commenced a permanent survey for the Whitney dam across the Mississippi River. It will probably be 550 feet in length and cost about $50,000.

WILLMAR.—J. T. Otos, City Clk., writes that W I. Gray & Co., of Minneapolis, have secured the contract for an engine, 120-kw. alternator, and steam and electrical appliances for the addition to the water and electric light plant for $5,300.

DULUTH.—The Great Northern Power Company is reported to have awarded to the Chicago Bridge & Iron Company, of Chicago, Ill., the contract for the erection of a steel standpipe 232 feet high, to be used in connection with its work of developing the water power on St. Louis River.

ST. PAUL.—A mortgage executed by the St. Croix Falls Improvement Company to the City Trust Company, of Boston, for $2,000,000, has been filed with the registrar of deeds. Bonds in the sum of $1,000 each, bearing five per cent. and due in thirty years, will be issued. It is recited that the loan is made for the purpose of getting a right of way for the construction and equipping of an electric transmission line from the power house of the company to Minneapolis, and for the purpose of constructing a distributing system in Minneapolis and elsewhere. A massive dam is being constructed at St. Croix Falls which will furnish power to Minneapolis, and in time to a number of other cities of the state.

MISSOURI.

EDINA.—The Edina Light Company has been incorporated, with a capital of $10,000, by Fred J. Wilson, Jane D. Wilson and Paul K. Gibbons.

COLLINSVILLE.—The Collinsville Gas, Electric & Refrigerator Company has been incorporated by Charles F. Slocum, of Belleville, John H. Seigel and W. E. Hadley, with a capital of $50,000.

WARSAW.—At a special election held recently the proposition to issue bonds to the amount of

$6,000 to build and maintain a municipal electric light plant was carried. The present plant has proved inadequate.

JERSEYVILLE.—Mr. R. W. Bivins, Springfield, Ill., has been appointed superintendent of the electric light plant owned by the Jerseyville Illuminating Company, to succeed Mr. J. J. Miller, resigned. Mr. Bivins was formerly connected with the lighting plants at Decatur and Arcola, Ill.

MONTANA.

HELENA.—A certificate of its articles of incorporation has been filed with the county clerk by the Helena Light & Railway Company, which has taken over the system of the Helena Light & Traction Company. The incorporators of the company, which is capitalized at $1,500,000, are Louis Sperry, of South Windsor, Conn., and Warren B. Johnson and Harry W. Reynolds of the same state.

NEBRASKA.

HOOPER.—William T. Martin has sold out his electric light business to W. A. Hough.

WISNER.—The town authorities of this city have awarded the contract for an electric light plant to cost $5,100.

HASTINGS.—The municipal electric light and power plant is being enlarged by the addition of a 400-h.p. engine and generator, costing between $15,000 and $20,000.

GRAND ISLAND.—The Grand Island Electric Company has been incorporated with a capital of $60,000 by Arthur F. Vila, G. H. Payne, Irving F. Baxter and others.

FREMONT.—The Fremont Gas and Electric Light Company of Fremont, Neb., has been bought by L. P. Funkhouser and other Lincoln men.

RAVENNA.—The village trustees are considering the question of constructing an electric light plant.

NEVADA.

ELKO.—The Intermountain Power Company is reported incorporated with a capital of $1,500,000 by E. J. Raddats, C. O. Ellingwood and W. J. Craig, to construct a power plant at this place.

NEW HAMPSHIRE.

KEENE.—The stockholders of the Citizens' Electric Company of this city have voted to increase the capital stock of the company from $35,000 to $50,000.

MEREDITH.—The directors of the newly organized Meredith Electric Light Company, residents of Providence, R. I., have decided to increase the capital stock of the company from $9,000 to $16,000, and to change the system to an alternating one. The power house at Meredith will be done away with, and power brought from Laconia.

EXETER.—The deed conveying the plant, business, good will, etc., of the Frank Jones Electric Company to the Rockingham Light & Power Company, a subsidiary company of the New Hampshire Traction Company, has been recorded. This company operated in Portsmouth, Newcastle and Rye, and the deed was executed by the trustees of the Jones estate.

NEW JERSEY.

NEW BRUNSWICK.—There is talk of a municipal electric light plant here owing to some dissatisfaction with the rates and service of the Public Service Corporation.

GLOUCESTER CITY.—The electric light plant of the Public Service Corporation and the powerhouse of the Camden, Gloucester & Woodbury trolley road, which is a part of the Public Service, are about to be closed, and the power for the electric lights and trolley road will be supplied from the Camden plant.

NEW MEXICO.

SANTA FE.—The City Council of Silver City has entered into a contract with the New Mexico Light, Heat & Power Company for the furnishing of lights to the city by said company for a period of two years, with the privilege of renewing the contract from year to year for a period of five years from date. The price for all lights now installed is to be 90 cents per light per month, and $1.50 per light per month for any additional lights the city may desire.

NEW YORK.

ALBANY.—The Chatham Electric Light Company has extended its line to Ghent.

LOCKPORT.—The Economy Light, Heat, Power & Fuel Company is stated to have petitioned Council for a franchise.

AUBURN.—The Auburn Gas Company has decided to purchase the plant and franchise of the Citizens' Light & Power Company, of Auburn.

AKRON.—The Niagara, Lockport & Ontario Power Company has filed with the Akron town clerk an acceptance of the franchise granted to it recently.

BUFFALO.—The Niagara, Lockport & Ontario Power Company has been granted a franchise by the town board of Newstead for a transmission line through that town.

HERMON.—The State Commission of Gas and Electricity has granted the application of the Hermon Electric Light Company to transact business and issue $15,000 of stock.

PHOENIX.—The Phoenix Fuel, Light & Water Company is reported to have been granted permission by the State Commission of Gas and Electricity to issue $100,000 bonds.

BINGHAMTON.—The trustees of the village of Port Dickinson have closed a contract with the Binghamton Light, Heat & Power Company for electric light service for the village streets.

ALBANY.—The Tremont Mills Utility Company, of New York, has been incorporated to supply electricity for light, heat and power. The directors are: S. K. Jacobs, C. A. Jacobs and E. L. Jacobs, of New York.

SOUTH GLENS FALLS.—The Bd. of Village Trustees is reported to have awarded the United Gas, Electric Light & Fuel Company the contract to light the village streets for five years, with 2,000-c.p. arc lights at $50 per light per year.

NEW YORK CITY.—The New York Edison Company reports that there are now connected with its mains in Manhattan motors aggregating 100,275 horse-power. Among new or pending contracts for the service of the Edison company is a supply of current for the New York Custom House. Contracts for the equipment of this building were announced recently.

UTICA.—Mr. C. A. Greenidge, who has been superintendent of the electrical department of the Utica Gas & Electric Company, has been promoted to the position of general manager of that department. Mr. William J. Cahill, who has been general manager of the gas department and secretary of the company, has retired as secretary, and Mr. M. J. Brayton, whose place at the head of the electrical department Mr. Greenidge takes, has been appointed secretary.

SYRACUSE.—The Syracuse Lighting Company is about to close a contract with the Niagara Falls Power Company for 10,000 horse-power. It is said that this is done for the purpose of forestalling competition. The transmission company, which is now engaged in securing rights of way, has reached as far as Monroe County. By March 1, power from Niagara Falls is expected to be operating the Rapid Transit Railway system in Syracuse, where a large sub-station will be built.

NIAGARA FALLS.—The Niagara Falls Power Company announces the following changes, occasioned by the death of the late William B. Rankine; Mr. deLancey Rankine has retired from the office of third vice-president of the power company, and it is understood that at its first meeting he will be chosen to fill the vacancy in the board of directors caused by the death of William B. Rankine. Mr. De Lancey Rankine will devote all of his time to the affairs of the Cataract Power & Conduit Company, of which company he is both treasurer and secretary. Mr. Philip P. Barton, heretofore superintendent of the Niagara Falls Power Company, has been appointed general manager of the business and operations of the company at Niagara Falls. The office of second vice-president remains unfilled.

NORTH CAROLINA.

LOUISBURG.—The question of constructing a municipal electric light plant is reported under consideration here.

GREENSBORO.—The Greensboro Electric Company has improvements to its plant under way, requiring the expenditure of $50,000.

MOREHEAD CITY.—It is stated that Cincinnati capitalists have closed a contract with J. W. Riley, of this city, to erect an electric light plant here, to cost about $15,000.

MOORESVILLE.—An election was held here recently for the issuance of $10,000 in bonds for the establishment of an electric light plant. The measure carried by a majority of 35 votes. This was the third time an election has been held for bonds for this purpose, but before water works and graded schools were coupled to the light proposition.

SALISBURY.—It has been found that the water power at Whitney, near Salisbury, with a dam proposed to develop 25,000 horse-power, will, on account of the larger size of the basin, be capable of developing 50,000 horse-power. It is expected that the company, in which Mr. E. B. C. Hambley, of the Whitney Reduction Company is interested, will have 50,000 electrical horsepower on the market in two years. The contracts have been let for the dynamos, water-wheels, etc., comprising six units of 8,000 horse-power each. It is said that when the first 50,000 horse-power is developed, there will be 50,000 horse-power additional awaiting attention and that this will be developed, making a total capacity of 100,000 horsepower at the company's plant on the Yadkin River.

NORTH DAKOTA.

FARGO.—William and S. Mainland have sold their interest in the Union Light, Heat & Power Company. Paul Doty was elected president and O. G. Barnes secretary of the re-organized concern.

OHIO.

PORT CLINTON.—The Port Clinton Electric Light & Power Company will add a district heating system to its plant.

LOVELAND.—The Loveland Citizens' Electric Company has decided to issue $50,000 bonds, to be used for the extension of the plant.

LIMA.—Notice has been given of the increase of capital stock of the Lima Electric Railway & Light Company from $850,000 to $1,250,000.

DEFIANCE.—At a meeting of the city council a resolution was introduced declaring it necessary to bond the city in the sum of $50,000 for the purpose of erecting and maintaining an electric light and gas plant.

FOSTORIA.—A committee has been appointed by the Board of Trade to look into the matter of establishing a municipal electric light plant. The present electric lighting contract with the city expires in August next.

HAMILTON.—The board of directors of the Hamilton Gas & Electric Light Company has passed a resolution ratifying the expenditure of $250,000 in improvements on the electric light plant and the Otto Coke Works.

OBERLIN.—The Oberlin Gas & Electric Company has been taken out of the receivers' hands and refinanced by J. C. Hill, of Elyria; A. E. Hay, of Oberlin, and others. The company will install a heating plant and will make important improvements to the lighting plant.

GALION.—According to the statement just issued by the service department, the cost of maintaining and operating the street arc lamps of this city by the municipal plant is but $27 a light per year. Much of the actual cost is paid from the earnings of the commercial department of the plant, leaving but a small balance to be paid by the taxpayers.

LOUDONVILLE.—The electric light plant at this place was almost totally destroyed by fire recently. The city will be in darkness for weeks, and the water supply will be cut off, as the plant furnished the power for pumping the water into the reservoir. The plant was owned and operated by the city and was valued at $10,000. The loss is partially covered by insurance.

EAST LIVERPOOL.—The East Liverpool Traction & Light Company has taken over the property of the United Power Company and the East Liverpool & Wellsville Electric Railway Company, according to reports, and Edward McDonnell, of Buffalo, has taken the place of L. W. Healy, principal owner and manager of the companies. The East Liverpool and Rock Springs railway line and the Rock Springs Park are to be taken over later.

DAYTON.—The Dayton Lighting Company has awarded to G. M. Gest, the expert subway contractor of New York and Cincinnati, a contract for the construction of a complete electrical subway system. This plant has recently been acquired by new interests, who are rebuilding and re-equipping the entire plant. The contract given to Mr. Gest is for subway installation for the whole city, covering 20 miles of streets, and involving over one million feet of conduit. The system is to be modern and up-to-date, the amount involved being in the neighborhood of $250,000.

OKLAHOMA TERRITORY.

GEARY.—The Geary Electric Light & Power Company has been incorporated, with a capital of $3,000.

OREGON.

ROSEBURG.—The citizens have voted to issue bonds for an electric light plant and water works.

ASTORIA.—W. W. Whipple is reported to have secured a franchise to construct an electric light and gas plant and telephone system.

BAKER CITY.—The Fremont Power Company, of which John Waterman, John T. Thomson, of Sumpter, Ore., and Walter Fernald are the incorporators (capital, $200,000), will build the Olive Lake power plant near the Red Boy Mine immediately.

PENNSYLVANIA.

MYERSTOWN.—This town is to have electric lights, to be supplied by feed wires run from Lebanon.

ALBION.—The question of constructing water works and an electric light plant is under consideration here.

NEW CASTLE.—W. A. Burney, representing the Davannah Lighting Company, was recently granted a lighting franchise by the city council.

ELLWOOD CITY.—The Ellwood Electric Light Company has completed arrangements by which it will conduct electricity to Zelienople for lighting and power purposes.

BIRDSBORO.—The Birdsboro Electric Light & Power Company will erect a power plant along the Schuylkill road, and secure the power for running its dynamos from the upper level of the canal by turbine water wheels.

YORK CITY.—The announcement of the preparations which have been made recently for the building of a gigantic hydro-electric plant near McCall's Ferry, on the Susquehanna, by the corporation known as the McCall Ferry Water & Power Company, capital $10,000,000, has revived the Conowingo Falls power plant project.

PHILADELPHIA.—The Tremont & Pine Grove Electric Light & Power Company has sold its plant to Philadelphia, Williamsport and Lancaster capitalists for $30,000. The new owners will extend the lighting facilities to Donaldson on the north, and to Pine Grove, south of Tremont. It is also proposed to connect these towns by trolley.

LANCASTER.—The directors of the Edison Electric Illuminating Company and the Lancaster Gas Light & Fuel Company are reported to have awarded to the Providence Engine Company, of Providence, R. I., the contract for enlarging the electric light plant at Engleside, for $165,000; also to the United Gas Company, of Philadelphia, the contract for constructing a new gas plant, for $100,000.

PHILADELPHIA.—The contract for street lighting for the city of Philadelphia during 1906 has been awarded to the Philadelphia Electric Company. The company was the only bidder for the contract, its bid being $1,073,271.55. This is $118,205.25 less than the estimated cost of the work, the calculations being based on the amount expended this year. Electric lighting cost the city $1,135,508 this year, and in 1904 it spent $1,085,055.

BETHLEHEM.—The Bethlehem borough council has entered into a new contract with the Bethlehem Electric Light Company. The borough agrees to pay the light company the sum of twenty-three cents per lamp per night, instead of twenty-seven and one-half cents, as per old contract, and the sum of $18 per annum for each incandescent lamp. The borough agrees to use a minimum of 137 arc lamps. The light company is to accept payment for all arrears of light at the rate of twenty-five and one-quarter cents per lamp per night. The new contract, which calls for $800 worth of free lighting, is to become operative on and after November 1, 1905.

RHODE ISLAND.

NEWPORT.—The council committee on street lighting has been authorized to ask for bids for the erection and installation of a municipal electric lighting plant.

WYOMING.—It is reported that an electric plant is to be built at Wyoming, with a view to supplying electricity for the different business places in the two villages, and possibly for street lighting.

SOUTH CAROLINA.

BAMBERG.—An election will probably soon be held to vote on issuing bonds for water works and an electric light plant; probable cost, $25,000. G. Moye Dickinson, Mayor.

ANDERSON.—Joseph E. Sirrine, of Greenville, has prepared plans for the electric power plant which is to be constructed at Hatton Shoals on Tugalo River, to develop 5,000 horse-power for the Hatton Shoals Company, of which R. S. Ligon, of Anderson, is president.

GAFFNEY.—The fine water power at Gaston Shoals, on Broad River, near Gaffney, it is reported, will soon be developed. It was recently sold to John B. Cleveland, of Spartanburg, S. C., and others by the Gaffney Manufacturing Company. Electrical power for several towns will be available.

TENNESSEE.

MARTIN.—The city officials will put in about $1,300 worth of improvements at the water and light plant here.

CHATTANOOGA.—The Chattanooga & Tennessee River Power Company has been reorganized, with C. E. James, of Chattanooga, president; J. C. Guild, of Chattanooga, chief engineer, and John Bogart, of New York, N. Y., as consulting engineer. The contract, together with the $100,000 bond which has been made between this company and the Government for the building of the lock and dam for the power plant on Tennessee River, it is stated, has been approved by the War Department.

TEXAS.

TEXARKANA.—S. E. Whiteside and G. West have applied for a franchise for an electric light plant.

HUMBLE.—The electric light and power plant was destroyed by fire recently, involving a loss of $10,000.

ORANGE.—The Orange Ice, Light & Water Company has been incorporated, with a capital of $60,000, by Samuel C. Trimble, W. H. Stark and P. B. Curry.

FORT WORTH.—The Consumers' Light & Heating Company, of this city, was recently organized, with George W. Armstrong president and R. C. Armstrong, Jr., secretary.

WICHITA FALLS.—The Wichita Falls Water Works Company has changed its name to the Wichita Falls Water & Light Company, and increased its capital from $50,000 to $75,000.

UTAH.

PROVO.—W. E. Harding, City Recorder, writes that it is proposed to construct water works and an electric light plant, at a cost of $91,000. Engineer, Frank C. Kelsey, Salt Lake City.

SALT LAKE CITY.—The Inter-Mountain Power Company is preparing to build a system of hydro-electric plants near Salt Lake City, with steam auxiliary. The capacity will be 5,000 horse-power. Plans and specifications are in course of preparation by Frank C. Kelsey, Salt Lake City.

COALVILLE.—A power plant of 2,000 horse-power capacity is projected in this city by the Intermountain Electric Company, the plant to be auxiliary to those already in operation in the Cottonwoods. The new plant will furnish electrical energy for practically all the towns in Summit County. The company has a capitalization of $1,500,000.

TOOELE CITY.—The Clark Electric Power Company, of this city, has secured a franchise from the City Council to erect poles for the installment of electric lights at Grantsville. Work has been commenced on the erection of poles from Tooele City, a distance of twelve miles, and it is estimated that Grantsville will be lighted by the first of November.

PROVO.—The Telluride Power Company contemplates the early establishment of a second electric power plant, to be located at a point on the Duchesne. The plan is to provide electrical energy for mining purposes, and also for distribution in Salt Lake, Park City, Mercur, Eureka, Price and Bingham. The company has made application to the State engineer for 61 feet of water in the Duchesne.

OGDEN.—E. W. Wade has been looking into a proposition relative to the construction of a power plant on the river 17 miles out of Blackfoot, Idaho. Christian Just, of Blackfoot, and others are interested in the project. Mr. Wade states that by the construction of a canal about 1,500 feet long a power plant could be established without building a dam and 1,000 horse-power developed. The power could be increased by erecting a dam. The plan is to furnish light and power to Idaho Falls and Blackfoot. The cost of the project is estimated at $100,000.

VERMONT.

MONTPELIER.—The Consolidated Light & Power Company has increased its capital stock from $350,000 to $1,000,000. The increase was voted last May, when the plant changed owners. The Bolton Falls plant of the company is to be doubled next spring. The present capacity is 2,000 horse-power, and water turbines and machinery will be put in to make the output about 4,000 horse-power.

VIRGINIA.

ASHLAND.—The Virginia Light & Power Company, recently incorporated, proposes to furnish a light and power service. No engineer has been appointed yet, and no bids have been asked for.

RICHMOND.—As to the proposed municipal electric light and power plant, the city attorney has been requested to prepare an ordinance for the issue of $500,000 light plant bonds. The plant proposed will have a capacity of 2,000 horse-power.

PETERSBURG.—Judge Waddill, of the United States District Court, having authorized the receivers of the Virginia Passenger & Power Company to expend $41,000 for the completion of the work on the water power plant of the company in Dinwiddie County, near Petersburg, the work has been resumed near the dam and a large force of laborers is employed. The company has already spent about $100,000 on the plant.

WASHINGTON.

CHINOOK.—The Chinook Light, Power & Water Company is reported incorporated, with a capital of $10,000, by Albion L. Gile and others.

CENTRALIA.—The Kilbourne & Clark Company, of Seattle, is reported to have secured the contract for constructing an electric light system for Centralia.

SPOKANE.—The Spokane-Palouse Light & Power Company is reported incorporated, with a capital of $100,000, by W. E. Goodspeed, B. H. Kiser and others.

BRICKLETON.—H. T. Latham, who operates a flour mill here, has secured an option on electric machinery in Portland, Ore., with a view to installing it to furnish commercial lights in this town.

OLYMPIA.—The Pend O'Reille Electric Company, of Spokane, has filed articles of incorporation, with $50,000 capital stock, by J. L. Drumheller, W. G. Malloy, Joseph Scott and D. M. Drumheller.

PORT TOWNSEND.—The City Council is reported to have received an application from W. A. Pfeiffer for a franchise to construct and maintain an electric light and power plant in connection with a gas plant.

BELLINGHAM.—Stone & Webster, of Boston, Mass., are reported to have purchased the Nooksack power plant from the Bellingham Bay Improvement Company, and will probably expend about $200,000 in improvements.

SPOKANE.—The Big Bend Water Power Company has been organized by J. H. Tilsey, John E. Peterson, Reuben Cross and others, to develop 15,000 horse-power about 28 miles down the river. E. Tappan Tannant is the engineer.

TACOMA.—Bids will be received until November 8 by L. W. Roys, city clerk, for constructing a hydro-electric generating plant of not less than 5,000 and not more than 10,000 horse-power, delivered on the low-tension side of the transformer at the distributing station.

SEATTLE.—The demand for light and power for commercial purposes has been so heavy that City Engineer Thomson and Superintendent L. B. Youngs, of the Water and Light Department, will soon make arrangements for increasing the municipal lighting plant by installing another hydro-electric unit at a cost of $15,000. There are now two units with a capacity of about 3,500 horse-power, and with the third one the capacity will be increased to 5,000 horse-power.

TACOMA.—The Nisqually River water rights, right of way, etc., owned by John L. McMurray, of this city, have been transferred to the Thompson Company, the consideration being named as $75,000. The new interests of the company will be known as the Nisqually Power Company, which has been incorporated with a capital stock of $100,000. The company, it is stated, proposes to establish power-houses, electric generating plants and flume line. It secures 1,500 cubic feet of water per second from the stream. Easement for electric transmission lines is also granted. The stream, it is said, can develop fully 5,000 horse-power at the point where the company's power-houses are to be located, and those interested believe that at least 5,000 additional horse-power can be generated.

WEST VIRGINIA.

MARTINSVILLE.—The citizens voted recently to issue $12,000 bonds to complete the electric light and power plant. J. R. Gregory is the city engineer.

WISCONSIN.

OMRO.—The village will change the electric street lighting from arcs to incandescent.

PORT WASHINGTON.—The proposition to issue $75,000 in bonds for water works and electric light plant has been carried.

LITTLE CHUTE.—The village board has granted a franchise to the Kaukauna Electric Company to furnish electric lights.

FOND DU LAC.—At the next meeting of the common council some action will probably be taken on the application of the Independent Light, Heat & Power Company for a franchise granting it the privilege to establish a plant here.

CANADA.

PORT FRANCES, ONT.—The council is considering the installation of an electric light plant.

OSHAWA, ONT.—The Oshawa Light & Power Company has been incorporated, with a capital of $100,000.

VANCOUVER, B. C.—It is reported that the estimated cost of constructing a municipal plant has been placed at $500,000.

MONTREAL, QUE.—A by-law is before the city council requiring that all overhead wires in the city be put underground.

VICTORIA, B. C.—M. Hutchison, city clerk, writes that the improvement to the electric light plant will be made by the Hinton Electric Company for $9,025.

CHATHAM, N. B.—This town is reported to have voted to apply to the Legislature for power to issue $35,000 bonds for the construction of an electric light plant.

TORONTO, ONT.—The city received authority at the last session of the Legislature to expend $40,000 for a new electric light plant on the Island, and the matter is now being undertaken.

WOODSTOCK, ONT.—By a vote of 427 to 165, the by-law to raise $50,000 for improvements and extensions to the electric lighting and water works plants of this city was carried by the property holders.

TORONTO, ONT.—The Georgian Bay Power Company, of Toronto, has engaged H. von Schon, Detroit, Mich., to plan a development of Eugenia Falls on Beaver River, Ont., where a head of about 400 feet will be available.

CURRIES LANDING, MAN.—A syndicate composed of Canadian and American capitalists intends developing the water power on the Assiniboine River at Brandon, Man. The intention is to erect a large power house and plant at this city.

OTTAWA, ONT.—The Dominion government has passed an order granting permission for the construction of a dam across the Rainy River at Fort Francis. This proposal has been before the government for a long time, and electrical interests have been urging for the power to make the improvement.

WESTMOUNT, QUE.—The Robb Engine Company is reported to have secured the contract for the engines, accessories and their erection in connection with the new electric light plant for $8,300. The Custodis Chimney Construction Company secured the contract for building the chimney for the plant at $6,250.

ST. CATHARINES, ONT.—The council has passed a by-law granting the Cataract Power Company a 25-year franchise, for which the city gets, free of cost, 215 incandescent lights of 16-candle-power capacity, which is estimated to be worth $1,000 a year. In addition the company is to erect a generating station at Decaw Falls. This will make the cash value of the extensions about $150,000. The Toronto & Niagara Power Company has also applied for a similar franchise to that granted the Cataract Power Company, which was also carried, but held over, and not to come into force until the company has handed over to the city a lease of its hydraulic canal for water works purposes.

WINNIPEG, MAN.—The development of electric current from a water power at Lac du Bonnet on the Pinnewa channel of the Winnipeg River, about 30 miles from here, is rapidly approaching completion. At the present time over 1,000 men are employed. The power house is completed and is almost sufficient for the transmission of 10,000 horse-power. The rock excavations in the channel are also about completed. Already no less than 75,000 cubic yards of rock have been moved. This will provide sufficient water for the ultimate development of 30,000 horse-power, which will supply power to the street railway for running its cars, the balance being used for power and light for the city, and also power for the manufacturers.

OTTAWA, ONT.—The Ottawa Electric Company, in order to prevent all possibility of impaired service owing to the carrying out of works of improvement, shortage of water, anchor ice, etc., has decided to install a steam reserve plant of considerable capacity, in addition to the steam plant already owned and operated by this company as an emergency plant. The new installation will consist of a Westinghouse-Parsons steam turbine direct-connected to a 2-phase 1,500-kw. alternating-current generator. The exciter will be mounted on a bracket and on the turbine frame, and direct-connected to the turbine shaft, and there will be other sources of current for exciting the field, which will be available at any time in case of failure of the exciter. The boiler capacity will be sufficient to operate the turbine and generator to the highest limit allowable for overload when desired.

TORONTO, ONT.—Frederic Nicholls, general manager of the Canadian General Electric Company, and also a director of the Electrical Development Company, states that all the plans are about completed for the extension of the power-transmission lines through the western peninsula of Ontario, from Niagara Falls. London is the objective point from the Falls for the present. Plans are complete and surveys will be made at once, going through Brantford, Paris, Galt, Guelph, Berlin, Hespeler, Woodstock, Ingersoll and the smaller towns, and supplying electric power to all the electric railways for operating purposes. The power house at Niagara will be completed sooner than was expected, as the steel frame for this is now being erected. The overhead work from Niagara has been completed, with the exception of a few intersections, where legal formalities have to be complied with. Power is promised for Toronto within three months, but not enough at first to run all the street cars.

MONTREAL, QUE. — The equipment of the power plant of the Kaministiquia Power Company, now being erected at Kakabeka Falls, near Fort William, Ont., will be the best that can be secured. A part of it has been contracted for in Germany, while the motors, transformers and other equipment will be supplied by the Canadian General Electric Company. The actual water head is 181 feet high, which is considerably higher than at Niagara Falls. It is the intention of the company to generate 30,000 horse-power, the first installation on which work is now being rushed, being 10,000 horse-power. The company expects to deliver power into Fort William about June 1 next, and the indications are that the entire amount of power that will be available will be readily disposed of. In addition to contracts with the Ogilvie Flour Mills Company, which will take 1,000 horse-power, and the town of Fort William, power will be sold to the Canadian Pacific and Grand Trunk railways. A large American industrial company will also take power from the company.

MEXICO.

LA BARCA.—Francisco Castellanos proposes to establish an electric light and power plant at La Barca.

VERA CRUZ.—An electric power plant will be installed on the Laguna de Catemaco, State of Vera Cruz, by Juan Simon Rodriguez.

CITY OF MEXICO.—Ignacio Saldana will install a large electric power plant on the Rio del Salto. He has made application to the federal government for a concession.

CULIACAN.—Diego Redo will install an electric power plant on the Tamazula River, in the State of Sinaloa. The power will be transmitted to industries and towns of that section.

CITY OF MEXICO.—Vicente Martinez, of the City of Mexico, will build an electric plant for the transmission of electric power at Xicotlacotia between the states of Morelos and Guerrero.

CITY OF MEXICO.—Luis E. Reyes, of the City of Mexico, will establish an electric power plant in the State of San Luis Potosi, at a waterfall on the Los Naranjos River. The electric power will be transmitted a considerable distance.

CORDOVA.—George G. Bergman, of the City of Mexico, has applied to the federal government for a concession to install a large electric power plant on the Blanco River, near Cordova. The electric current will be transmitted to towns and industrial centers in that region.

GUADALAJARA. — Compania Industrial de Guadalajara, which operates two electric power plants situated on the Santiago River, near Guadalajara, will compete with La Electra Company for business of furnishing electric lights and power in Guadalajara. It is stated that its plants will be enlarged and other extensive improvements made.

MERIDA.—The Merida Electric Light Company and the city council are involved in a dispute over the delay by the company in placing its wires underground. The council has informed the company that if it does not fulfill its obligations in the matter within six months the council will proceed to bury the wires and charge the work to the company. Furthermore, the company will be fined for its delay.

SAN IGNACIO.—Jose H. Rico, president of the Guadalupe de los Reyes Mining Company, has made application to the federal government for a concession to install and operate an electric light and power plant near this city. The company which he represents will erect a dam at the juncture of the Plaxtla and Arroyo rivers and obtain water power for operating the electric plant from that source. The power will be transmitted to towns of that section, and will also be used for operating the machinery of the mines of the Guadalupe de los Reyes Mining Company.

American Electrician.

Vol. XVII. New York, December, 1905. No. 12.

ELECTRIC TRANSMISSION AND DISTRIBUTION IN VERMONT.

HYDRO-ELECTRIC GENERATING STATION AND SUB-STATIONS OF THE CHITTENDEN POWER COMPANY AT RUTLAND.

The Chittenden Power Company is about to place in operation its new power plant located about five miles from the City of Rutland, Vermont, one sub-station in the City of Rutland, and one sub-station at Castleton Corners, about 15 miles distant from Rutland, in a direction opposite from the power plant. The system will supply the Rutland Street Railway Company with power to operate the city railway line in Rutland, and an interurban road from West Rutland and Castleton to Fairhaven. Power is at present supplied from a steam generating plant located about midway between Rutland and Fairhaven. The situation of this plant is such as to necessitate considerable hauling of coal and other supplies, which with the present price of coal at Rutland undoubtedly means high generating cost. The building of the new plant was started last fall and it is just now receiving the finishing touches.

A reservoir is located above Rutland among the hills and an extensive dam with head-gates and spillway has been constructed at that point for retaining sufficient water supply to maintain continuous plant operation throughout the year.

Immediately above the reservoir which supplies the present plant is located a much larger reservoir, which can be developed later, and which will undoubtedly produce a greater quantity of power than the new plant does at present.

From the upper reservoir to the present reservoir, a 400-ft. head can be utilized. From the lower reservoir a pipe line 5 feet in diameter and 5000 feet in length, is carried down the valley to the new power plant, giving to this plant a head of somewhat over 200 feet. The 5-ft. pipe line is constructed of steel plate throughout, lap welded and double-riveted in all seams towards the latter end of the run, and lap-welded with a single row of rivets at the head of the run. Considerable excavation was necessary in order to properly install this pipe line, as the low temperature prevailing in this country during the winter months made it imperative that the complete line should be covered up.

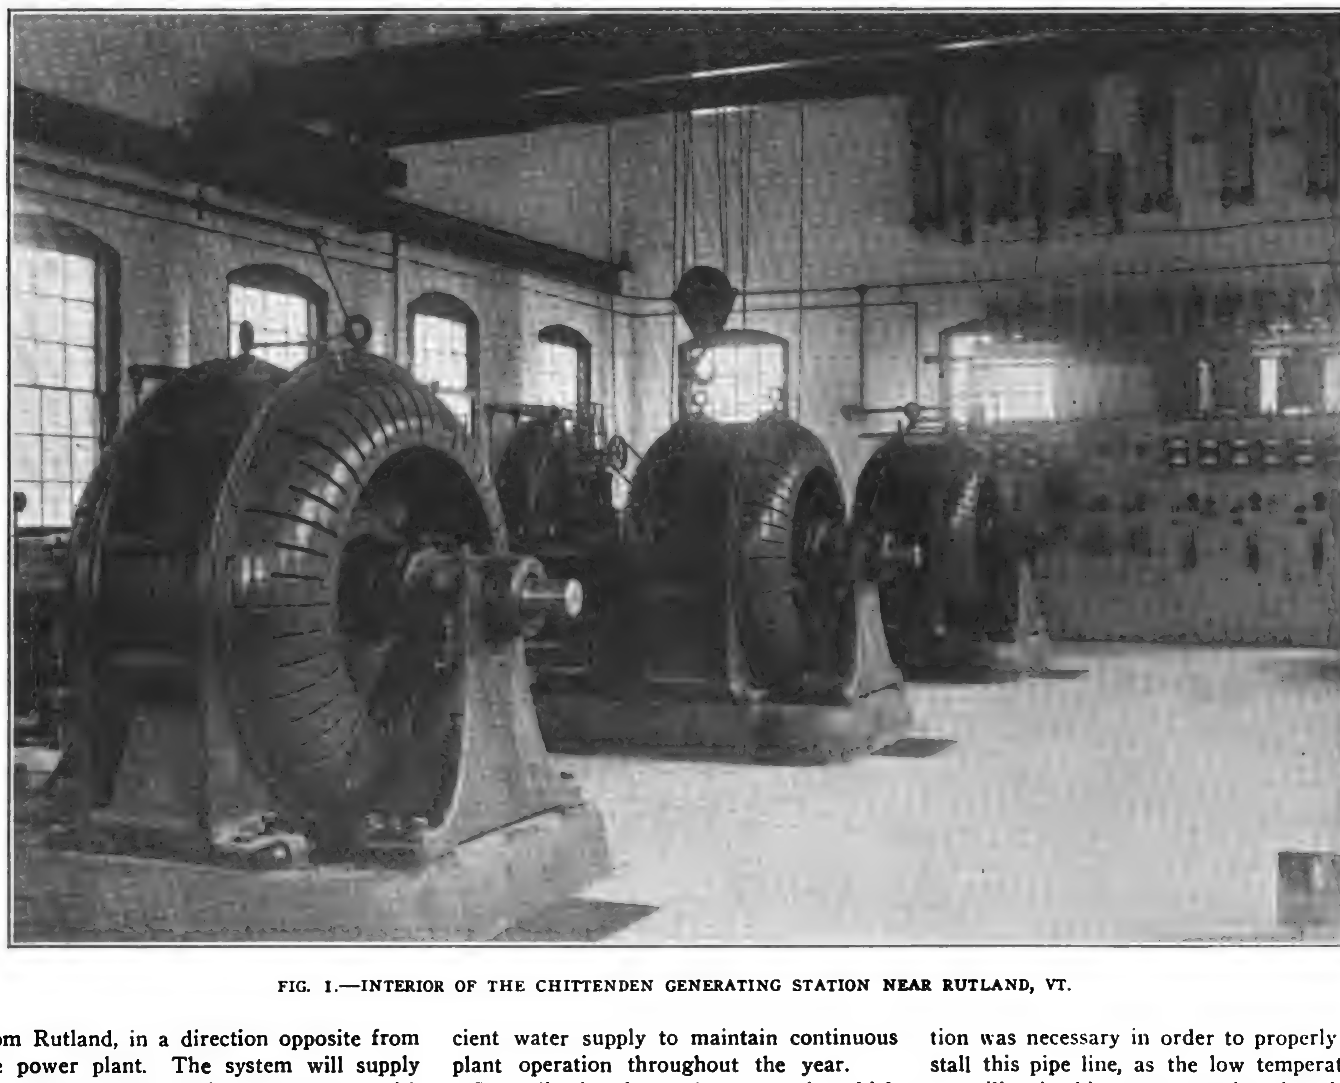

FIG. I.—INTERIOR OF THE CHITTENDEN GENERATING STATION NEAR RUTLAND, VT.

The power station is a brick structure with steel trusses and concrete slab roof. There are no purlines in the roof construction, as the slabs for the roof were

moulded in forms set up on the ground, and after hardening were transported to the site of the power house—a distance of about 300 feet; removed from the forms; hoisted to the roof and properly attached to the steel trusses. After being leveled the joints were pointed up with neat cement and a finished roof covering of roofing felt and an asphaltic compound installed. These slabs are 4 feet wide, 8 feet 6 inches in length, 3½ inches in thickness, reinforced with 3 inches No. 10 expanded metal, and are composed of one part cement, 2 parts coarse, sharp sand and three parts clear, crushed stone, or gravel. Considerable gravel was used in the concrete work for foundations, floors and roofing for this building, as gravel was readily obtainable from the beds of two creeks which flowed one on each side of the power house. The sand for construction purposes was also conveniently located as a bank was found close to the power house site and on top of the hill. In order to utilize this sand it was only neces-

FIG. 2.—PIPE LINE.

FIG. 3.—VIEW OF POWER HOUSE SHOWING WATER TOWER.

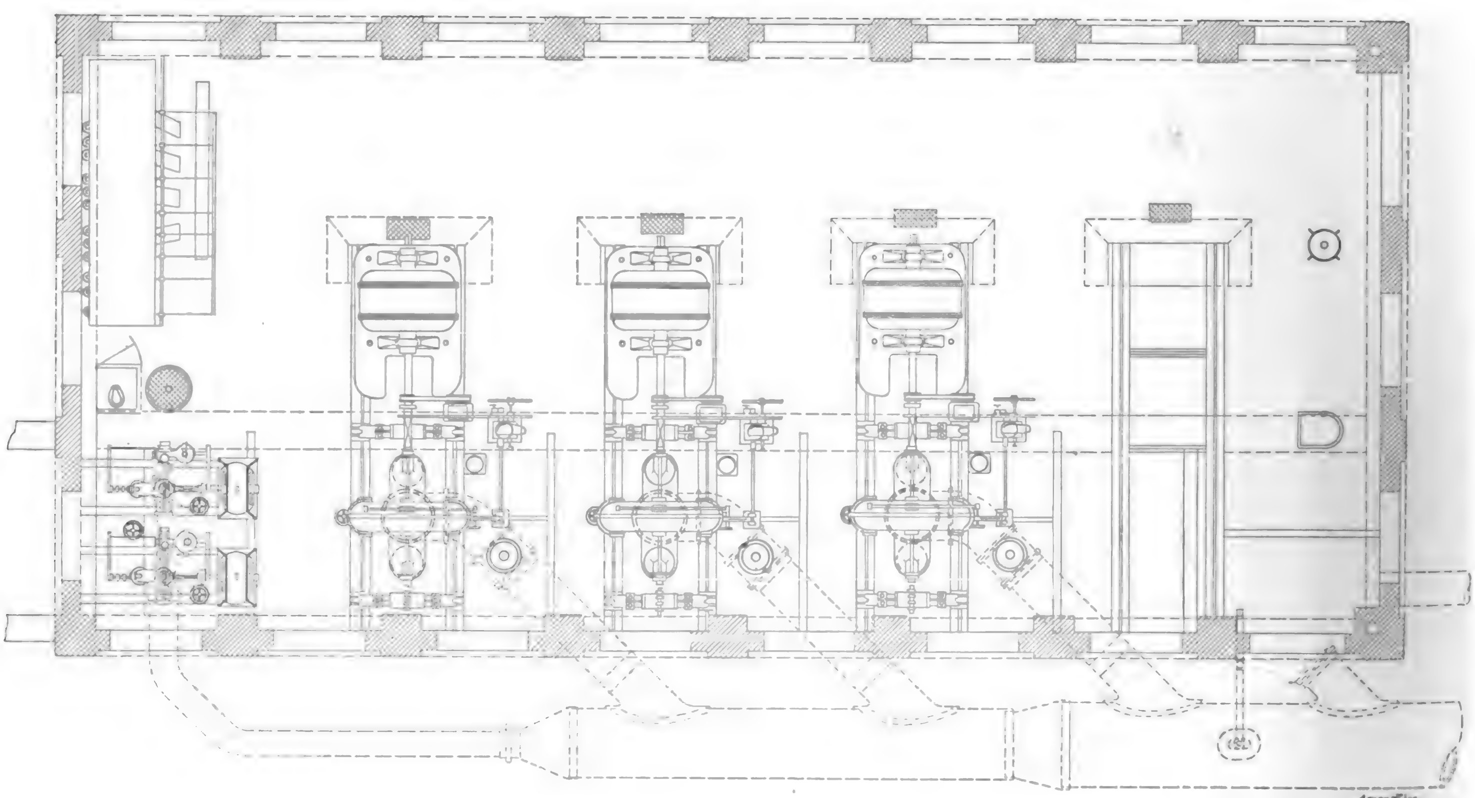

FIG. 3.—PLAN VIEW OF MAIN STATION.

sary to install a sheet-iron chute which deposited the sand at the proper location.

The pipe line is carried along the side of the building, and branches are taken in to four turbine wheels. A smaller branch is also taken in to supply two exciter wheels. Any of these branches can readily be cut out by gate-valves, which are installed on the branches close to where these enter the building. Pressure in this pipe line is maintained constant, and pounding or water hammering eliminated by the installation of a regulating tower 220 feet high having a tank of sufficient capacity to relieve the wheels of fluctuations in pressure in the pipe line.

The tank referred to is 16 feet in diameter and 50 feet high. It is built of bent steel plates properly riveted together, with a hemispherical bottom, also constructed of heavy steel plates properly riveted. A frost-proofing of wood encases the steel tank. The space between the frost-proofing and the steel tank is supplied with heat by a steam pipe running from a heater located in the power house to prevent freezing of water in the winter time.

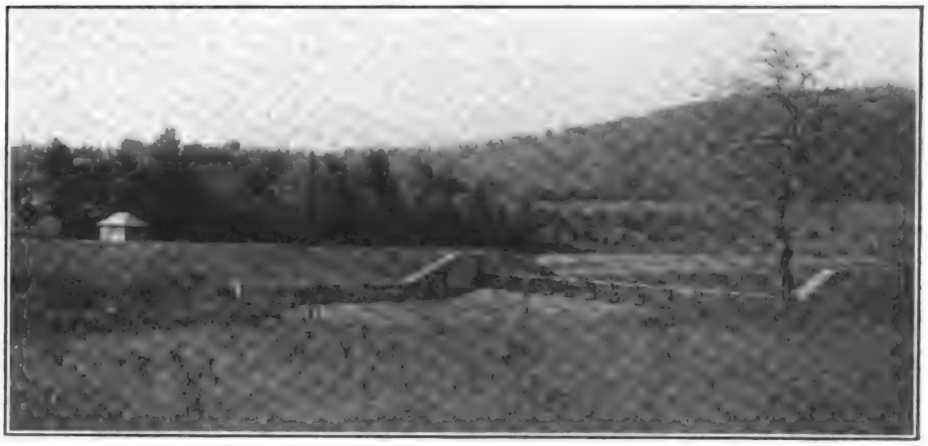

FIG. 5.—HEADGATE AND SPILLWAY.

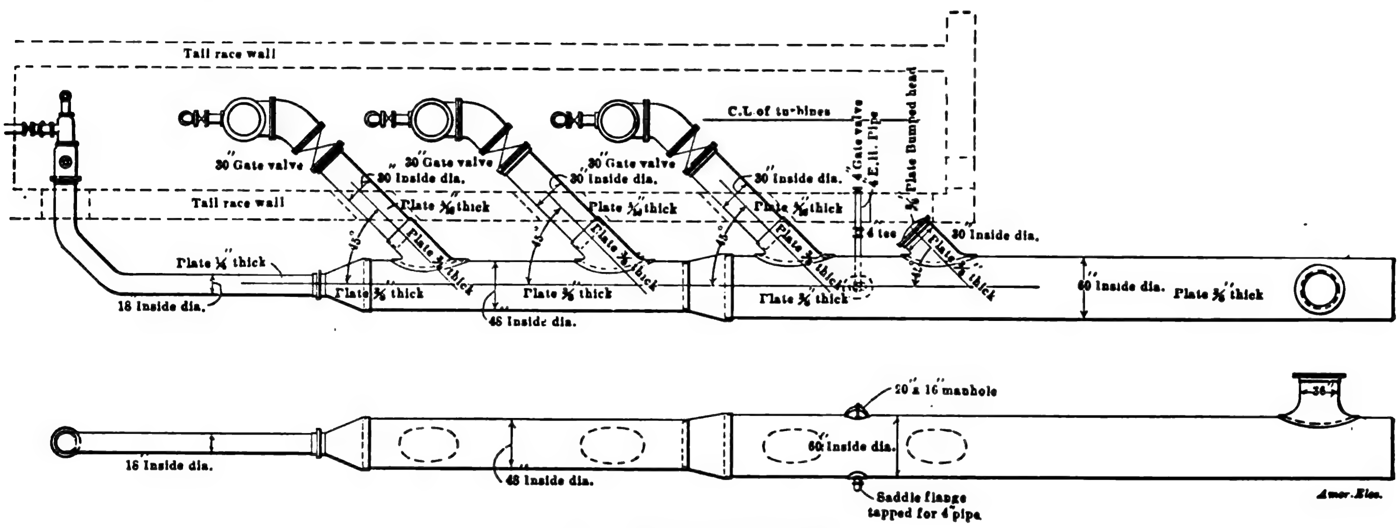

FIG. 4.—DETAIL OF PENSTOCK.

The tank is supported on four lateral channel legs with sufficient struts and diagonal bracing to make a very stiff structure. Access to the tank from the ground is obtained by climbing the lateral braces on one of the columns. A circular platform surrounds the bottom portion of the tank.

The run of the penstock is directly below and in line with the overhead tower. An 18-inch riser pipe supplies the tower with water. This pipe is encased within a 36-inch overflow pipe, which takes care of the

FIG. 6.—TRANSMISSION LINES.

FIG. 7.—REAR VIEW OF STATION SHOWING TAIL RACE.

fluctuations of the water lever, when suddenly shutting off or starting up the wheel.

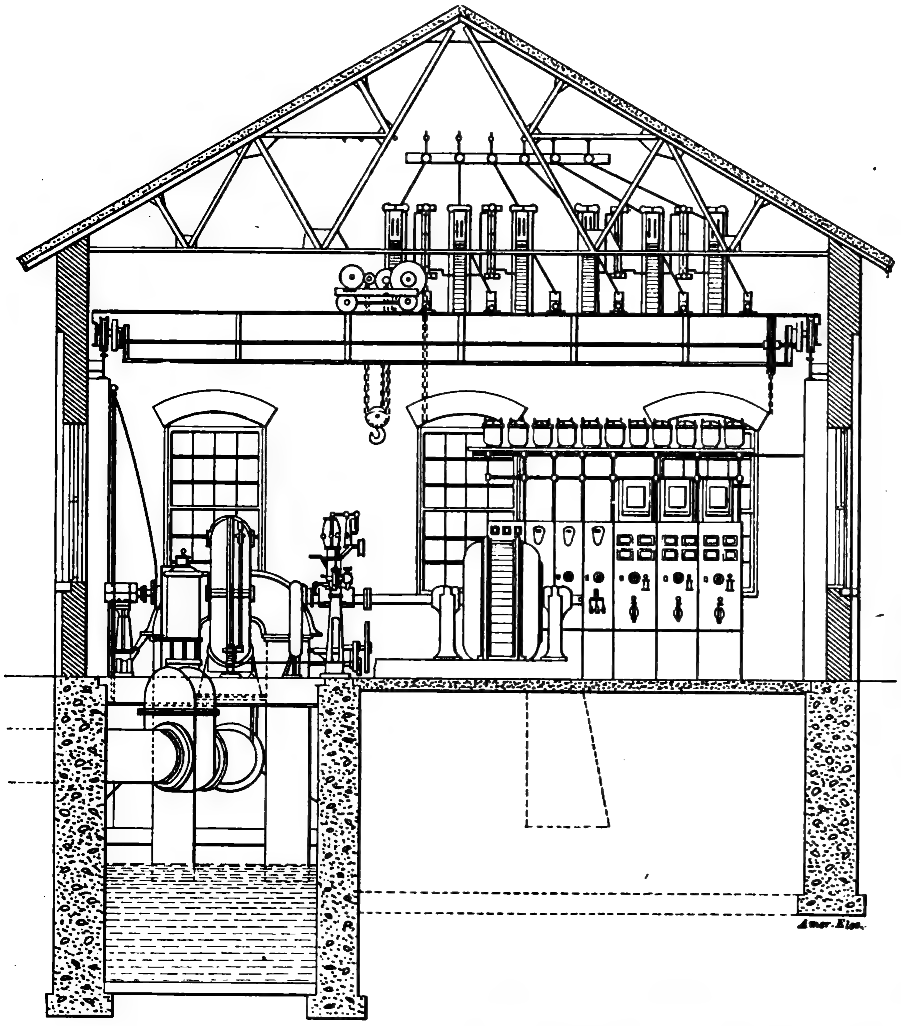

FIG. 8.—SECTIONAL ELEVATION OF MAIN STATION.

The space between the supply pipe and the overflow pipe is heated from the same system which heats the space between the steel tank and the frost-proofing.

The tail race is located immediately under the wheels and is carried about 150 feet beyond the power house, where it empties into the waste stream from the reservoir. It has concrete sides and bottom, and has a Weir plate installed outside of the power house for the purposes of measuring the water used.

The power house at the present time contains three 400-kw. revolving-field, alternating-current generators, with provision for the installation of a fourth unit. These are directly connected to three double discharge water wheels, which develop 770 horse-power at full gate opening. The wheels are enclosed in cast iron, manholes being provided for easy access to all parts, and supplied with 30-inch diameter supply pipe set to receive water from below. A 30-inch hydraulic valve controls the water supply to the wheels. All wheels are independently governed by Lombard type "F" governors. The generators are designed to run at 500 r.p.m., and to develop an e.m.f. of 13,200 volts.

Two exciters of approximately 25 kilowatts capacity are installed, and driven by small water turbines under the same pressure as the large wheels. Indicating devices for recording pressures and head of tail water, etc., are installed, and an indicating and recording tachometer is provided for each wheel; in fact, no pains have been spared to provide a hydraulic equipment which will be permanent, and insure satisfactory and continuous operation, under the varying conditions of load which are naturally met with in a railway installation.

FIG. 9.—TURBINE-DRIVEN EXCITER UNITS.

The switchboard to control this installation consists of panels for controlling the exciters, independent generator panels for each of the generating units, a regulating panel complete with automatic regulator for keeping the pressure constant at the delivery end of the transmission line, and two three-phase line panels. The generator and line panels are provided with high-tension oil switches mounted in concrete cell compartments and are hand-operated from the face of the switchboard.

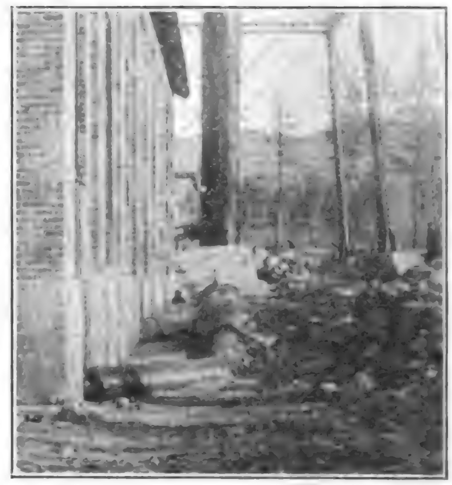

FIG. 10.—PENSTOCK.

All wiring for power in the building is encased in lead-covered cables, and has a working capacity of twice that under which it will operate. The power house lighting wiring is entirely encased in iron conduit, incandescent lamps being used throughout.

To facilitate the dismantling and repairing of machinery, the building is provided with a hand-operated overhead crane, and every means has been taken to insure easy operation and comfort to the operators.

From the power plant two three-phase, 13,200-volt transmission lines are carried in an air line mostly on private right of way, to the Rutland sub-station, located near the center of the City of Rutland, and from this sub-station one three-phase transmission line is carried to the Castleton sub-station, located on the main street of Castleton Corners.

These transmission lines are protected by lightning arresters, located within the buildings at each of the stations, and are so provided with high-tension switching apparatus, that either of the two transmission lines from the power house to the Rutland sub-station, can be used, or the two can be thrown in parallel. The switching apparatus in the Rutland sub-station has been installed so that the Castleton sub-station can be operated on either of the lines from Rutland to the power house, or can be disconnected from the main line and can be operated on the same lines with the Rutland sub-station, thus allowing entire flexibility of the transmission system, and eliminating all possible danger from interruption.

The Rutland sub-station is a brick structure with a concrete roof, this roof being built in place. The building is located on property controlled by the Chittenden

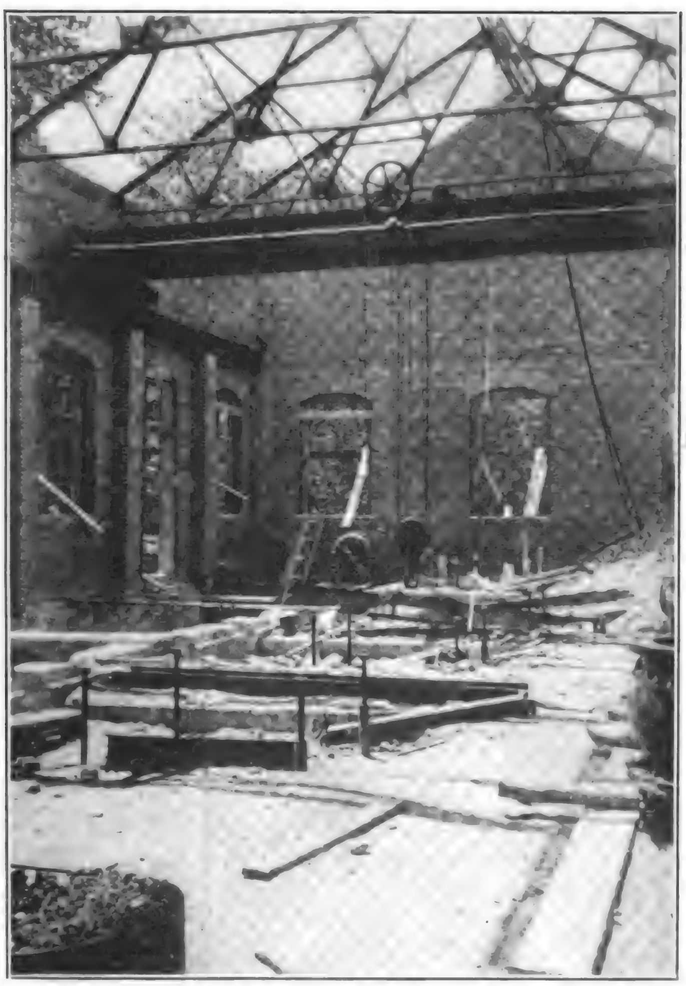

FIG. 11.—MAIN STATION IN COURSE OF ERECTION.

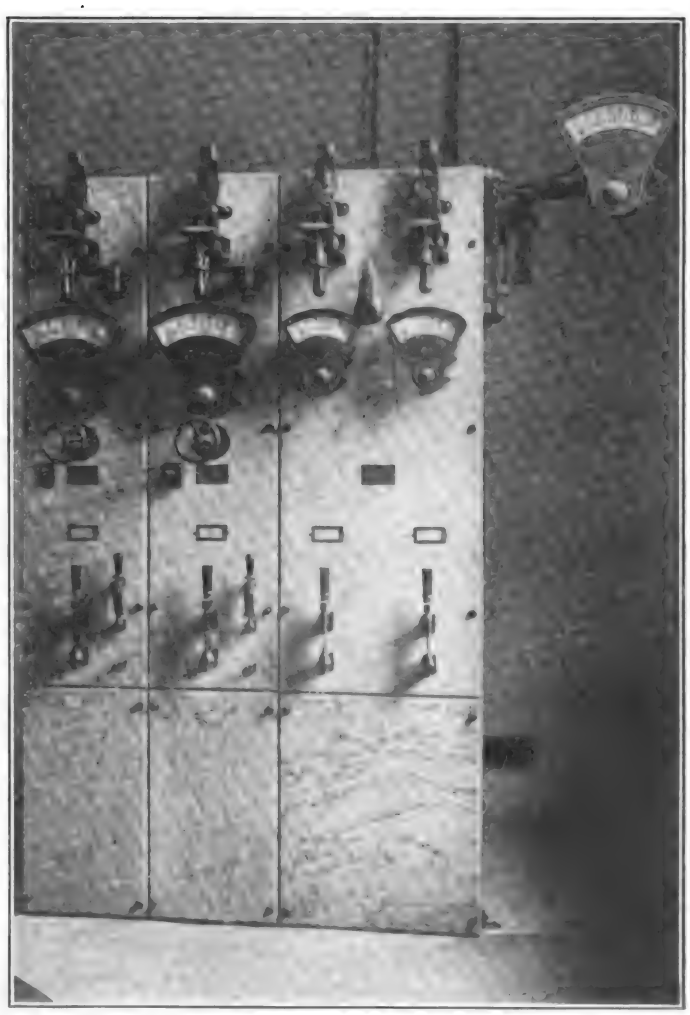

FIG. 13.—SUB-STATION SWITCHBOARD.

Power Company, and located in the vicinity of the company's gas works. The building is of adequate size to contain the present apparatus, and later addition of one unit making a total of three 150-kw. rotary converters. One side of the interior wall

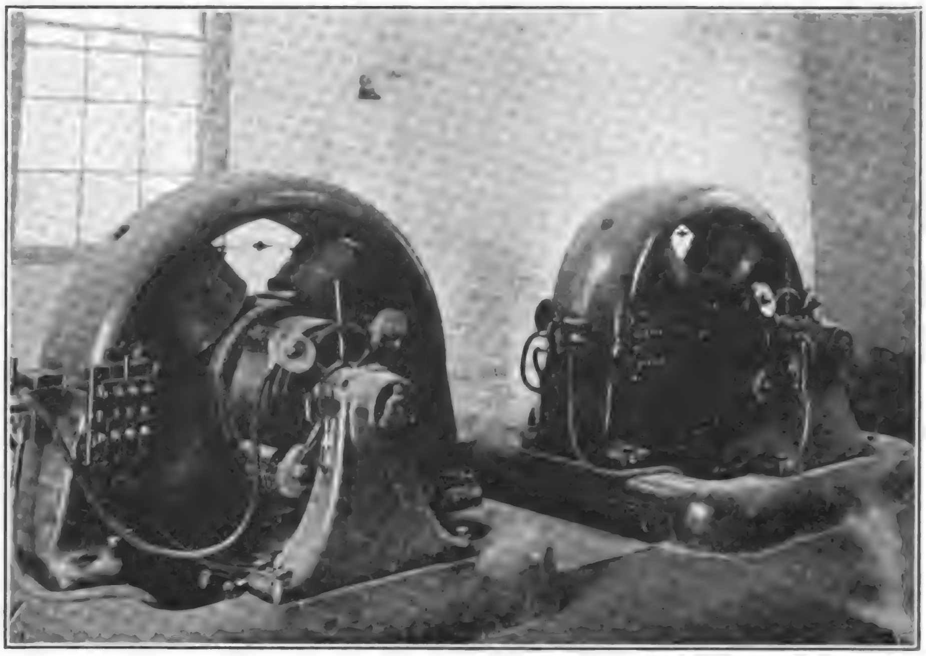

FIG. 12.—ROTARY CONVERTERS IN SUB-STATION.

is devoted to high-tension switching apparatus and lightning arresters, in accordance with the above-described installation.

It is calculated that the transmission pressure at the entrance to this sub-station will be about 12,500 volts, which pressure is carried through high-tension oil switches, mounted in brick compartments, and thence to three 125-kw. air blast transformers connected in delta on the high-tension side. The low-tension side of these transformers is provided with double windings and connected in double delta, the secondary e.m.f. being 370 volts. These transformers are

air-cooled and all wiring and connections on the low-tension side are in the air pits under the transformers.

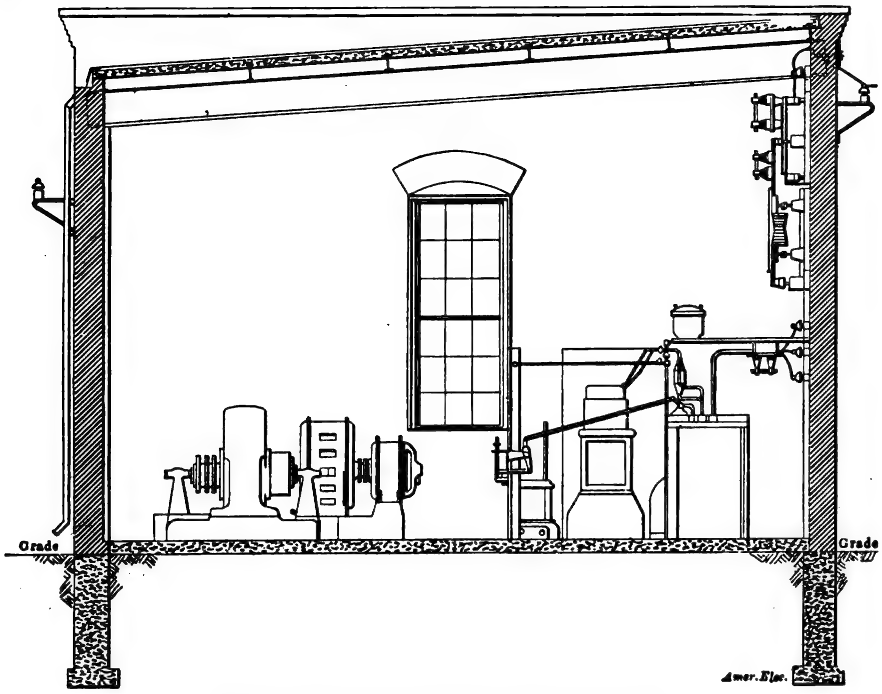

FIG. 14.—SECTIONAL ELEVATION OF SUB-STATION.

The reactance coils are also air-cooled and are equipped with the necessary switching apparatus, for starting the rotary converters from the half voltage taps of the transformers, thus reducing the power consumption at the time of starting the rotaries, and allowing better regulation throughout the system.

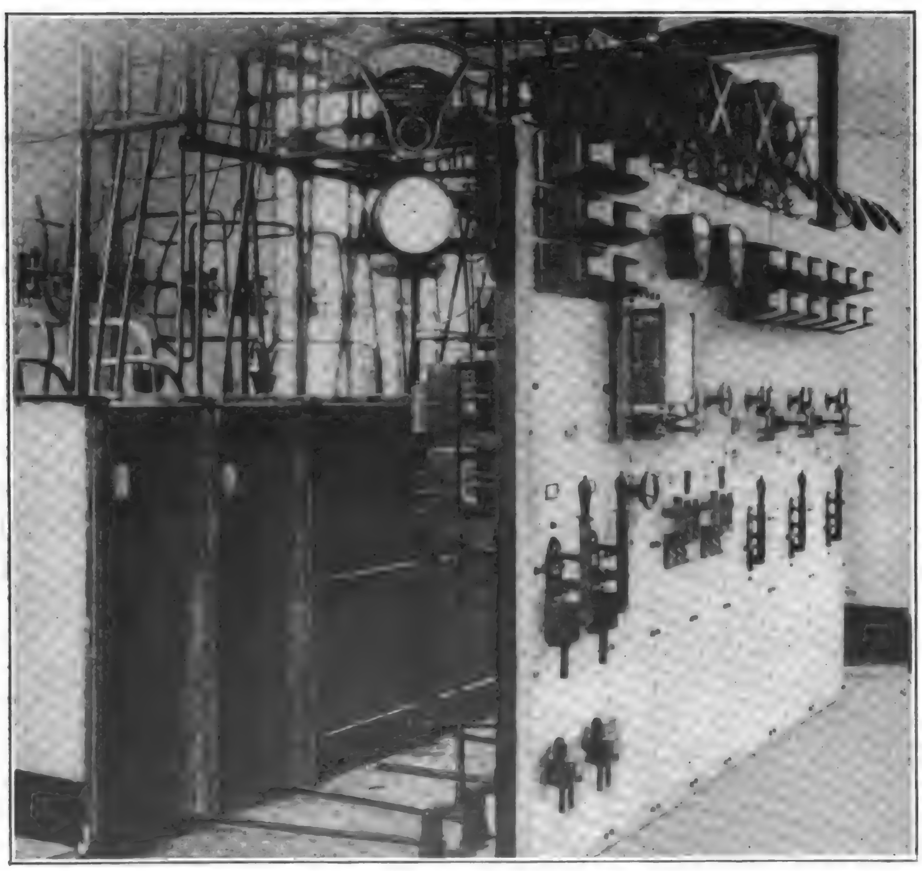

FIG. 15.—SWITCHBOARD IN MAIN STATION.

The low-tension wiring in these sub-stations, as in the case of the power house, is lead-covered, but paper insulation has been substituted in the sub-station in place of the rubber insulation used in the main power house. All open, high-pressure wiring in the stations is rubber-covered. The high-tension oil switches are hand-operated, from the high-tension line panel, which is also equipped with the necessary high-tension instruments.

This sub-station, as before stated, contains at the present time two 150-kw. rotary converters, which converters are installed over the wiring pits. All wires and cables are carried from one piece of apparatus to another in camp conduit, laid in the floor of the buildings.

The rotary converters are each provided with a direct-current rotary panel and an additional line feeder panel for controlling the various railway feeders. This panel is equipped with the necessary indicating and recording instruments and lightning arresters.

The transformers have duplicate blower sets, each of sufficient capacity to supply requirements, and each of these blower sets has its operating panel.

The Castleton sub-station building and equipment are the same in all general details as those of the Rutland sub-station, with the exception that the rotaries and their accessory apparatus are of different sizes, there being installed at the present time one 150-kw and one 200-kw. rotary converter, with adequate space for a future installation when conditions require it, of a further 200-kw. rotary converter.

The design of the entire system is such as to insure continuous and satisfactory operation under the worst conditions of load which are imposed by a railway system operating a city and interurban service. J. G. White & Co., of New York City, were the general contractors for the entire equipment and French & Bryant, of Boston, Mass., were the engineers for the Chittenden Power Company. The complete penstock work from the dam to the regulating tower and all the transmission lines were designed and installed by this latter firm.

STEAM ENGINE LUBRICATION.

BY R. T. STROHM.

Next in importance to a good lubricant is a proper device for feeding that lubricant to the bearings. No matter how excellent the lubricant, nor how painstaking the engineer in selecting it, there will be trouble if the lubricator fails to supply the bearing regularly and continuously with the necessary amount of lubricant. It is the purpose of the succeeding paragraphs to describe the construction and operation of various lubricators as applied to the steam engine, with the exception of those used in cylinder lubrication.

The crosshead guides are usually oiled by means of stationary sight-feed oil cups, which may be placed directly on the frame, or upon the guides. In case the guides consist of four rectangular bars, it is common to screw the oil cup into the upper guide bar on each side. The oil passes down through a hole in the guide and is distributed by the movement of the crosshead.

Most horizontal stationary engines are built so as to run over. That is, the crankpin passes over the shaft while the engine is making its forward stroke. Under these conditions there is little pressure on the upper guide, the greater portion of the pressure and the wear coming on the lower guide. Consequently, positive means should

be used to lubricate properly the lower slide. That is, the oil should be carried to the guide and there distributed, instead of chance drops being allowed to fall thereon.

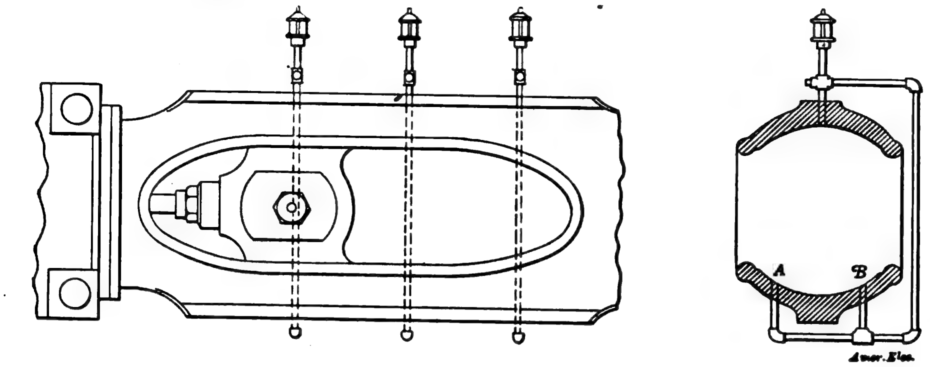

FIG. 1.

One method of securing positive lubrication of the guides of a Corliss engine is shown in Fig. 1. Three oil cups are used for the lower guide, one located near the mid travel point of the cross-head, and the others near the extreme points of travel, while a single cup attached to the frame at the mid-stroke position suffices for the upper slide on which the pressure is slight. The pipes leading from the cups to the lower guide are branched and each is tapped into the lower guide bar at two points, *A* and *B*, thus insuring good lubrication. To assist still further the distribution of the oil along the surface of the guides, the cross-head shoes are frequently grooved, these grooves serving to carry the oil to all parts of the bearing surfaces.

On vertical engines oil pipes may be tapped into the guides, at both sides, near the top, and the oil cups placed on these. It is not uncommon, however, to find an additional arrangement for lubricating the guides. To the bottom edge of each cross-head shoe is sometimes attached a piece of sheet brass or copper which is bent so as to fit flat against the surface of the guide. The lower edge of this sheet is cut into saw-tooth form, and at the end of the downward stroke these saw-teeth dip into an oil reservoir attached to the guide. On the upward stroke the oil picked up from the reservoir by these teeth is distributed over the surfaces of the guides.

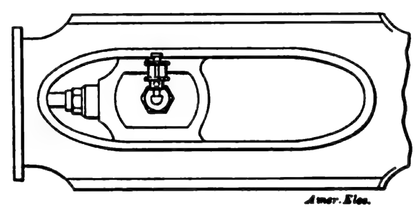

FIG. 3.

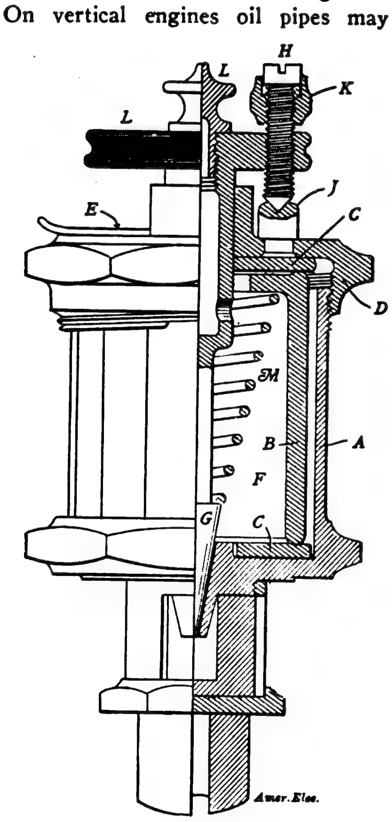

FIG. 2.

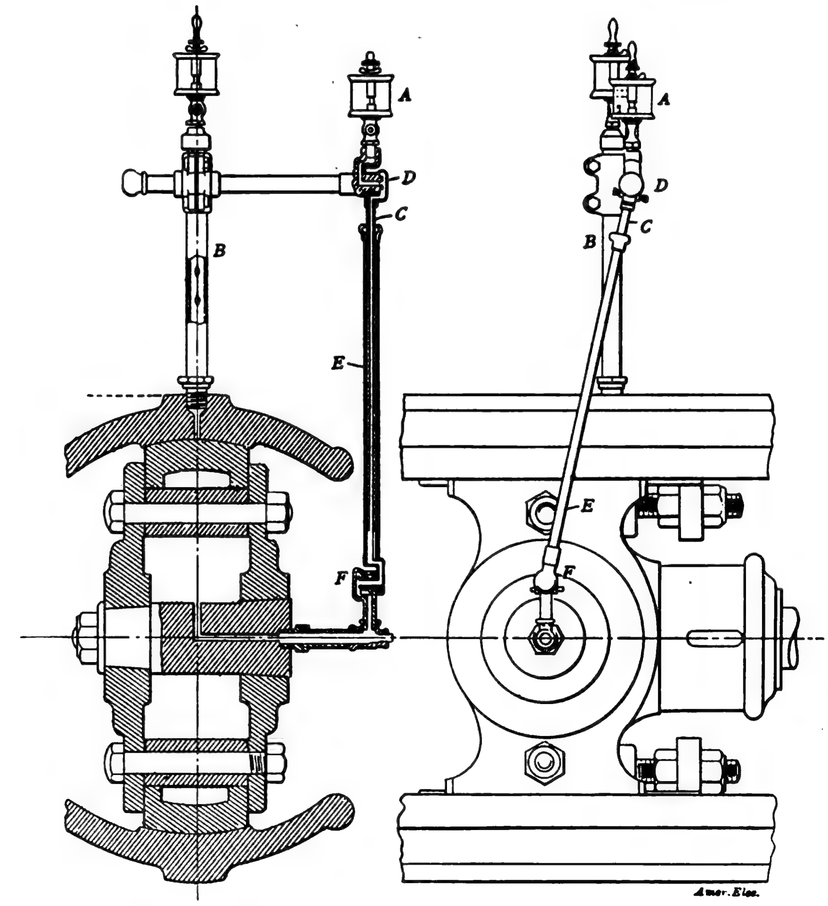

FIG. 4.

The construction of an oil cup should be such as to permit a regular and definite rate of feed for oils of varying viscosity, in order that the rate of supply of oil to a bearing may be found by trial adjustments and thereafter fixed. A form of cup embodying these features is shown partially in section and partially in elevation, by Fig. 2. The body of the cup, *A*, is of brass, enclosing a glass case, *B*, which rests upon cork washers, *C C*, at top and bottom. The glass case is firmly held between these washers by screwing down the brass cap, *D*. There is a hole beneath the slide, *E*, through which oil is poured into the oil chamber, *F*, of the cup. The slide prevents dirt and dust from finding its way into the oil chamber when the cup is in service. The oil is fed to the bearing through a hole in the bottom of the cup. The rate of flow is regulated by a conical valve, *G*, the position of which may be altered by the set-screw, *H*, at the top. When the cup is in use the set-screw bears upon a nipple, *J*, fastened to the cover of the cup. By turning the set-screw the valve, *G*, may be raised or lowered until the proper rate of feed is obtained. Then the thumb-nut, *K*, is tightened. When no oil is needed the wheel, *L*, is lifted and at the same time rotated slightly. This takes the set-screw, *H*, off the nipple, *J*, and the spring, *M*, then forces the valve, *G*, tightly on its seat. When the engine starts again the wheel, *L*, is lifted and the screw, *H*, is again returned to the nipple, *J*, when the cup will resume feeding at the same rate as before.

A simple method of oiling the cross-head pin is illustrated in Fig. 3. An oil cup is attached to a short ell of pipe which is screwed into the pin, a hole along the axis of the pin serving to convey the oil to the surface of the pin. This is a very con-

venient method where the engine runs for a portion of the day and is shut down over night. The periodical stopping permits the oil cup to be refilled, when necessary.

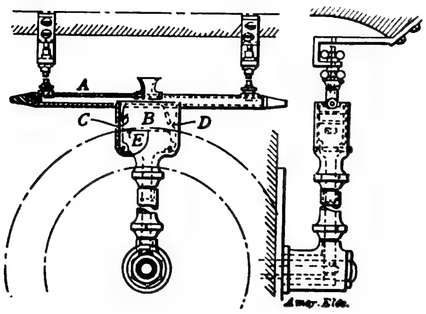

FIG. 5.

But where an engine is used on long, continuous runs, a wholly different method must be pursued. It is impracticable to fill a cup, attached as in Fig. 3, while the engine is in motion, and it would require an absurdly large cup to hold sufficient oil for a long run. Hence, the telescopic oiler, as shown in Fig. 4, has been produced.

The oil cup, *A*, is fixed by a horizontal arm to a rigid standard, *B*. The oil, upon leaving the cup, passes downward into the small pipe, *C*, by way of the spring joint, *D*. The small pipe, *C*, is enclosed by a larger one, *E*, which is in turn connected to another swing joint, *F*, at its lower end. The latter joint conducts the oil from the pipe, *E*, to the oil channel through the pin. The operation of the device is very simple. As the cross-head moves back and forth, the pipe, *C*, slides into and out of the pipe, *E*, the oil being thus conducted directly to the pin without wasting. This form of lubricator can be applied to vertical engines also, and to the lubrication of crank-pins and eccentrics, as well.

Another common method of oiling cross-

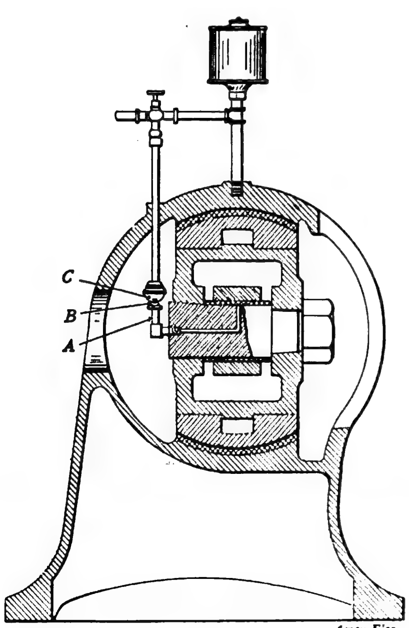

FIG. 6.

head pins is by the use of wipers. A device of this kind is illustrated in Fig. 5. A stationary oil cup, fastened to the engine frame, supplies oil to a horizontal tube, *A*, closed at the ends and perforated along the upper side by a number of holes. This tube is also held rigidly in place by connections to the frame. The wiper cup, *B*, is attached to the cross-head, and contains two wipers, *C* and *D*, pivoted at their lower ends and held together by a link, *E*, thus permitting them to move in unison on their pivots. They are so located in relation to each other that when the wiper, *C*, is vertical against the end of the cup, it just misses the lower edge of the tube, *A*, and wipes off the drops of oil which hang from the bottom of the tube. The other wiper, *D*, in the meanwhile is slanting and does not touch the tube, *A*. On reaching the end of the stroke towards the right, however, the inertia of the wipers throws them to the right so that *D* comes into a vertical position and *C* assumes a slanting posi-

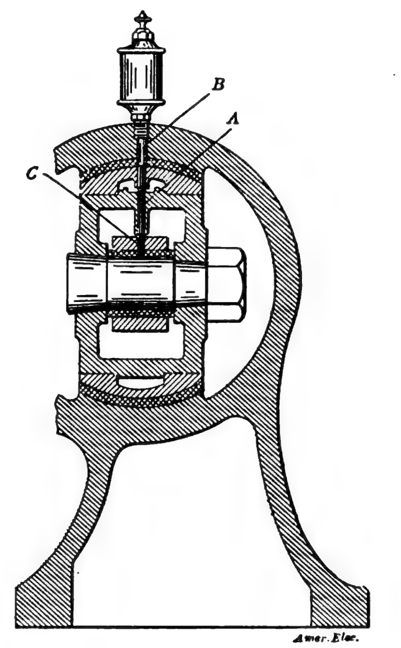

FIG. 7.

tion, the former wiping the drops from the tube, *A*, on the stroke toward the left. The oil thus collected in the wiper cup, *B*, is conveyed, by an oil hole in the pin, to the bearing surfaces. The tube, *A*, is capable of vertical adjustment, so that it can be raised or lowered to keep the edges of the wipers at the proper distance.

A different form of wiper is illustrated in Fig. 6. In this case the wiper cup, *A*, contains a single rigid wiper, *B*, which, at each stroke of the engine, passes under and touches the lower end of the oil pipe, *C*, which is fitted with a rounded cap, slotted in the center. The oil is then conveyed to the pin in the usual manner. This form of oiler is objected to by some engineers, especially by men running high-speed engines, for the reason that the rapid motion of the cross-head at mid-stroke, when the wiper is just touching the end of the pipe, tends to scatter or splash the oil all over the frame, floor and surrounding objects, which not only deprives the pin of lubricant, but also wastes the oil and spoils the appearance of the engine room. This action may be obviated by placing the pipe, *C*, very near the end of the stroke of the cross-head pin, since at that point the cross-head will have considerably less velocity than at mid-stroke.

In Fig. 7 is illustrated a method of oiling the cross-head pin in which neither a wiper nor a telescoping pipe is used. A hole, *A*, is drilled through the upper shoe of the

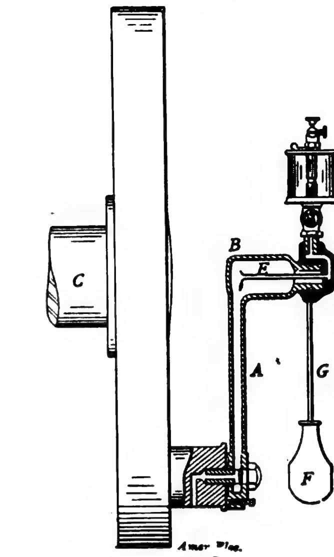

FIG. 8.

cross-head and cross-head frame, being so located that as the cross-head moves back and forth this hole matches with the hole, *B*, through the guide, by way of which the oil is supplied. Oil thus finds its way down through the channel, A, and drops into an oil hole, *C*, in the connecting-rod strap, by which it is led to the pin. This method, while not so positive as the others, has nevertheless given satisfactory results, particularly on the smaller engines.

The crank-pin may also be oiled in a number of different ways. The most common, perhaps, is the plain oil cup screwed into the connecting-rod strap and delivering oil to the pin through a hole in the strap. This method, however, is not applicable in cases where it is necessary to keep the engine in motion for long periods, without any stops, since the cup could not hold enough lubricant to supply the pin for the required time.

A solution of this difficulty lies in the use of a crank-pin oiler like that illustrated in Fig. 8. A hollow arm, *A*, is bolted rigidly to the crank-pin, the hole through the arm being connected with the oil hole in the pin, as shown. The end, *B*, of this arm is di-

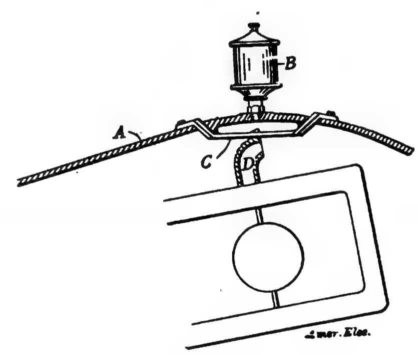

FIG. 9.

rectly on a line with the axis of the shaft, *C*, so that as the crank disc turns the arm, *A*, turns with it, the end, *B*, simply rotating without any lateral motion. The free end of the arm, *A*, has a journal formed upon

it, on which is placed the oil cup holder, *D*, the oil passing through a duct in the holder, to the pipe, *E*, and thence to the hollow arm, *A*. A weight, *F*, is suspended by a stiff rod, *G*, from the cup holder, and this weight serves to keep the cup always in an upright position. The oil which drips from the pipe, *E*, into the hollow arm is thrown outward by the centrifugal force and thus fed to the pin. By this device, every drop of oil that leaves the cup must eventually reach the crank-pin, so that waste and scattering of oil are avoided. An oiler of similar construction has the cup fastened to a stand which is bolted to the bed-plate of the engine. Both of these types are largely used at the present time on both horizontal and vertical engines.

On center-crank engines, however, it is impossible to use this scheme, unless an oil hole be drilled along the axis of the crank-shaft and along one arm of the crank to the pin. This is a difficult matter in case the shaft is long and the crank near the middle. A telescopic oiler, however, might be used, as described in connection with cross-head pin oiling.

Fig. 9 shows still another method. The crank is enclosed in a metallic casing, *A*,

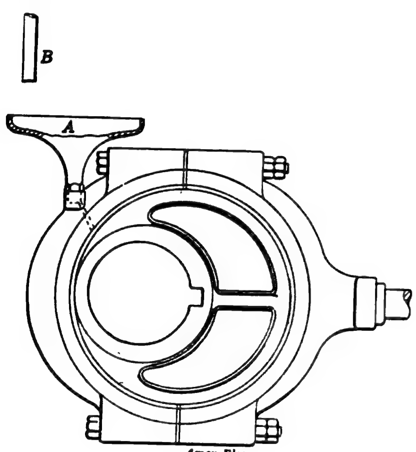

FIG. 10.

at the highest point of which the sight-feed oil cup, *B*, is placed. The oil from the cup drops upon a piece of wick, *G*, held by clamps on the inner surface of the casing. A hollow metallic wiper, *D*, is attached to the connecting-rod strap, and at each revolution the wiper touches the wick, taking off the drops of oil that gather on the under surface of the wick, and then, by oil channels, the lubricant is conveyed to the crank-pin. The casing, *A*, avoids the spattering of oil over the engine.

In some high-speed engines the lubrication of the crank-pin and of the cross-head guides is accomplished by splashing the oil upon them. To this end, the crank, connecting-rod and cross-head are enclosed by a casing, which, with the bed or frame of the engine, forms a chamber in which these parts may run. A bath of oil fills the lower part of this chamber to such a depth that at each revolution of the crank the end of the connecting-rod is partly submerged in the oil, while the crank-disk is always in contact with the oil bath. The result is that the oil is thrown into every part of the chamber, so that the crank-pin and cross-head pin and the cross-head slides practically run in an oil bath.

Objections have been raised to this method of lubrication on the grounds that the oil is not clean after a short period of running, since it contains the particles worn from the journals and brasses, as well as

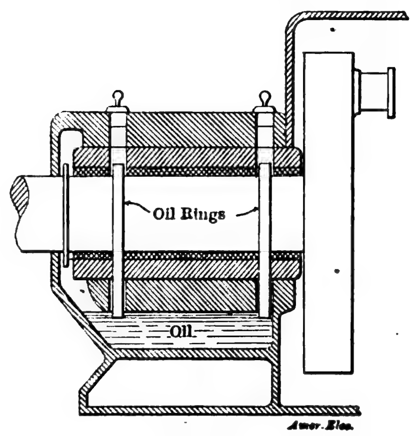

FIG. 11.

the dust that will find its way into the chamber, in spite of the best of care. In some engines, also, the condensation due to the leakage of steam from the stuffing-box mixes with the oil and this mixture is less valuable for lubricating purposes than clean oil.

It is furthermore urged that the splash method of lubrication possesses a very disagreeable feature in that when it becomes necessary to tighten the crank-pin in brasses or the cross-head shoes, the parts are all covered with oil.

Some builders avoid this method of oiling by substituting a continuous system, in which the oil is fed from some reservoir to the various engine bearings, the drippings caught, filtered and returned by a pump to a reservoir for further use. This forms a very clean and desirable mode of lubrication, which is growing in its application. One advantage is that the oil which reaches the bearings is always clean, and, therefore, in the best condition to perform its proper function.

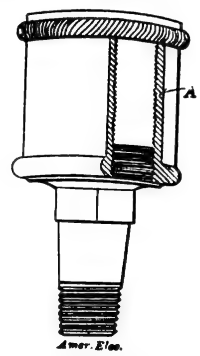

FIG. 12.

It is important that the eccentrics be well lubricated, since they are usually of considerable diameter and a large resistance due to friction is felt more quickly than on a shaft or pin of small diameter. An ordinary sight-feed oil cup is sometimes screwed into a hole tapped in the eccentric strap, and this does very well for intermittent running. But for long, continuous running, the oil cup must be stationary, so that it can be refilled easily. The telescopic oiler previously described may be used for eccentrics, and it answers the purpose admirably. Another very common form of oiling device for eccentrics is shown in Fig. 10. It consists of a long, narrow trough, *A*, terminating in a threaded tip which is screwed into the oil hole in the strap. The length of this trough is made slightly greater than the throw of the eccentric, and the oil pipe, *B*, from the cup is fixed vertically above the trough, so that the oil will drop into it, no matter what the position of the eccentric.

The usual method of oiling main bearings is by sight-feed oil cups screwed into the caps of the bearings, the distribution of the oil being secured by means of grooves cut in the seats of the bearing. In the larger engines this gives place to the gravity system already described. In other cases, principally in small high-speed engines, the ring oiling system is used, as illustrated in Fig. 11. As may be seen, the shaft is encircled by several rings which are much larger in diameter, internally, than the outside diameter of the shaft. These rings dip into a bath of oil formed in the base of the pedestal or frame, and, rolling on the shaft as it turns, carry oil to the top of the shaft, whence it finds its way, by spreading, to the bearings. In some cases the rings are replaced by loops of chain, but the action remains unchanged.

Thus far, only oiling devices have been considered. However, the use of greases for lubricating crank-pins and cross-head pins, as well as the various pins in the Corliss valve gear, has become quite extensive. These greases are fed from cups attached to the pin and moving with it. Frequently, the rate of feed is dependent upon the heat developed by friction in the bearing, this heat melting the grease and causing it to flow. Cups are made, as in Fig. 12, by which the feed can be regulated by hand. Screwing down on the cap, *A*, at intervals, forces the grease down to the pin. One of the best ways of feeding grease, however, is to use a spring compression cup in which a piston actuated by a helical spring, presses upon the grease in the cup and forces it out to the bearing. The tension of the spring may be adjusted to suit the consistency of the grease, and the outlet valve may be set so as to give the proper rate of feed.

A NOVEL STORAGE BATTERY.

BY DR. ALFRED GRADENWITZ.

A novel accumulator is being brought out in Germany in which the two electrodes are made of lead and zinc peroxide. Heretofore use of this couple has suffered serious drawbacks inasmuch as the zinc was dissolved by local action, thereby rendering its use in a storage battery practically impossible. Apart from this disadvantage, there was the difficulty of recharging such a battery, so that the couple referred to could practically be used only as a primary cell; that is to say, it produced electricity by the combustion of zinc. This confined its practical use from the very outset within rather narrow limits, since the cost of electricity produced from zinc is quite prohibitive.

In an endeavor to obviate the disadvantages of lead-zinc batteries, Mr. O. Von Rothmund constructed a regenerative primary element in which the zinc plates as they

became worn out were replaced by others, while the discharged lead peroxide plates were replaced immediately by other charged peroxide plates or were recharged themselves. The excessive consumption of zinc in this battery rendered its use to any large extent quite impossible, although a very high capacity was obtained.

Mr. Von Rothmund has recently succeeded, in conjunction with the firm of Ziegenberg & Co., of Berlin, in further increasing the advantages of the lead-zinc battery, the outcome being the storage battery shown in Fig. 1. In order to avoid any useless expenditures of zinc in the intervals of operation, a zinc alloy has been substituted, which, it is claimed, may be left in diluted acids for many weeks without any considerable amount being dissolved.

Engineers are aware of the difficulty of precipitating zinc by means of electricity in the form of a dense and adhesive coating on some other body. This difficulty is increased if zinc is to be precipitated on a zinc electrode. An extensive series of experiments was made in order to develop a process by which the lead peroxide electrode might be recharged and a zinc coating obtained simultanenously on the zinc electrode to render the latter suitable for immediate discharge. The lead-zinc battery thus passes from a primary cell to a secondary cell, although possessing features considerably different from those of ordinary lead accumulators.

The cell is said to produce 50 watt-hours per kilogram of battery in working order, and this may be increased to 70 or 80 watt-hours without interfering with its life. These high figures are due to the joint presence of different circumstances. In the first place, the couple, lead peroxide-zinc, represents a higher energy than is found in lead storage batteries, the ratio of the mean voltages being 2.35 to 1.95. A further increase in the capacity is obtained by using zinc plates which are thinner than lead sponge plates. The lead peroxide plates used in the new battery are also made by a special process, so as to possess excellent qualities, both from an electrical and mechanical point of view. Despite its mechanical strength, the plate is said to be extremely porous, which obviously insures a high capacity. Experiments made have shown the battery to successfully withstand short-circuits of several hours' duration, while yielding for short intervals twenty times the normal current; and this, without impairing its mechanical durability or decreasing its capacity to any permanent extent. As regards the life of the battery, no definite opinion can yet be had, as the results so far obtained do not extend over a sufficient period of time. Some positive plates are, however, available which have been discharged several hundred times, and these have, to all appearances, lost nothing in capacity or strength.

The mechanical strength of the battery is due to its practical design, as may be inferred from Fig. 1. A large hard-rubber box is separated into six compartments by hard-rubber partitions, and the whole is suspended in a protected casing of aluminum. The positive and negative plates are secured to frames on the edge of this aluminum casing. Each frame is placed on an elastic piece of rubber tubing and embedded in soft rubber. Connection of the plates with the various elements is effected by a system of springs. All solid connections are thus avoided. The plates are suspended in the hard-rubber box which only acts as the bearer of the electrolyte. This construction has been followed with a view to making the batteries of service in automobiles.

Regarding the practical operation and charging of the battery, there are various possibilities. As a zinc plate can be used in connection with several discharges the charge can be renewed by simply exchanging the set of positive plates for another freshly-charged set after renewing the acid. A greater advantage is offered by another

FIG. 1.—LEAD-ZINC BATTERY.

process in which the freshly-charged plates, before being placed in operation, are soaked in a vacuum apparatus with sulphuric acid. By this means the plates contain a sufficient amount of concentrated acid to be available for operation after being fitted up by merely pouring pure water over them. This soaking process affords other advantages, for the plates after being soaked have merely to be preserved in hermetically-closed vessels, in which state they can be kept a very long time without losing any of their charge. This affords a very suitable means of generating electricity in places having no central station or current mains. Current may be obtained by merely replacing the discharged positive plates by a set of charged or soaked plates. It should be remembered that the repeated use of zinc plates does not entail a consumption of zinc. The liquid remaining in the cell, which is an acid zinc sulphide solution, is used for direct recharging, so that the zinc in solution is recovered. The same zinc plates which have been used for several discharges are accordingly used for several recharges as counter electrodes with various sets of positive plates. Both sets of plates can, however, be recharged immediately after each discharge.

THE VALUE OF CONTACTS.

The importance of close contacts in the maintenance of circuit continuity has long been appreciated by electrical engineers. In the early days of telegraph and cable work the effect of a single loose connection at an instrument binding post was found to be sufficient to paralyze hundreds of miles of otherwise perfect line, and the years of experience which culminated in the commercial electric light and motor constantly brought home the lesson of the tight contact. In the signalling world it never has been a question of maintaining close contacts to prevent the dissipation of energy in heat, but the point has been, and is today, the preservation of the continuity of the circuit for the sake of the intelligibility of the signals themselves. Since the advent of the telephone the loose contact has been outlawed from all well regulated circuits, and there is no doubt that the wonderful sensitiveness of the Bell receiver is indirectly responsible for much of the improvement in circuit design exhibited in modern signalling apparatus, and anyone who examines the wiring of a modern central energy lamp signal relay telephone switchboard for the first time cannot but be impressed with the dependence of the industry upon soldered instead of twisted or clamped connections.

As one enters the power field the contact points in the circuits assume a new significance. Here the problem is distinctly a question of keeping down the temperature rise caused by the I^2R loss at the joints. If the contact is poor and the power supply ample, the resistance develops so much heat by the passage of the current that in time the switch points or blades become welded to the jaws—"frozen" in street railway parlance—and if the temperature still rises, the circuit finally breaks through the melting of the conductors, unless the fuses go first, which is generally assumed to be the proper order of events.

Even if the switches or connecting wires do not melt and set the premises on fire, but simply turn greenish-blue with heat, energy is being wasted to the detriment of the reasonable profits of the enterprise. Given plenty of power behind the switch, heavy overloads will cause trouble even in liberally designed contacts. There is always a point beyond which it will not pay to go in designing contacts, but after the maximum cross-section permissible has been named, it is still possible to increase the carrying capacity of the contact surfaces by the introduction of mechanical pressure by springs, compressed air or some other agency.

The influence of pressure upon contact resistance has been utilized in certain rheostat constructions, but the relation between the contact pressure and the temperature has not been widely appreciated. In a recent test of pneumatic unit switches designed for the Westinghouse multiple unit control system it was found that with a contact of one

inch and a pressure upon the contact of about 35 lbs., 300 amperes could be carried continuously with a temperature rise of 80 degrees, whereas with a pressure of 125 lbs. the temperature rise was but 50 degrees. With 210 lbs. pressure the rise was but 30 degrees, and at the latter pressure the same contact carried 600 amperes or 100 per cent. overload with 90 degrees rise. With 300 lbs. pressure 600 amperes gave 70 degrees rise. Supposing 70 degrees to be the limit of temperature rise allowed in a given case, the above switch would then carry anywhere from 300 to 600 amperes continuously provided the range of pressure available lay between 60 and 300 lbs. The use of compressed air in this way enabled the contact to be opened by springs powerful enough to act under almost any conditions which could be suggested, the usual magnetic blow-out principle being employed to prevent heavy arcing. In the light of these facts it is certain that the quantitative study of contact pressures is well worth while in large capacity switches and connections.

DIRECT-CONNECTED MOTORS IN TEXTILE WORK.

BY H. S. KNOWLTON.

The textile industry illustrates one of the most interesting fields of electric motor application, but until quite recently the group system of driving has been practised to the entire exclusion of direct-connected installations. This uniformity of motor application has been the natural result of service conditions demanding little or no speed variation in the individual processes of weaving and spinning, and it presents a marked contrast to the practice followed in machine tool driving, where speed variation constitutes one of the most essential elements of economical production.

Of late years competition in the textile industry has been keen, particularly between different sections of the same country, and the importance of lowering the production cost of each unit of output has been widely appreciated. Although the cost of power is not a large percentage of the total cost of manufacture in the textile industry, far-sighted mill managers have begun to see that any saving which can be effected without too great an initial expenditure is decidedly worth securing. The direct-connected motor is, therefore, being brought to the front in the interests of broad operating economy, and although these applications are still in a process of evolution, enough has been learned in actual commercial installations to determine pretty definitely the relative economy of direct connection and group driving in specific cases. The application of direct-connected motors to looms and spinning frames has passed far beyond the experimental stage, but in the close study now being devoted to the subject, minor improvements are constantly being introduced.

The individual drive received attention in Europe much earlier than in the United States, and as far back as 1894, motors were direct-connected to looms in households and factories in the vicinity of St. Etienne, France, with thoroughly satisfying results. Other installations followed, and in Lancashire, England, induction motors were direct-connected successfully to the ring frames in the cotton mills. Practically all the important textile driving in America and Europe has been done with alternating-current motors, which commend themselves particularly for this service on account of their elimination of sparking and resultant fire risk reduction, coupled with exceedingly low maintenance cost. Lint and dust constitute an inflammable combination in textile mills which deserves to be freed from the possibilities of ignition introduced by the sparking commutator. Squirrel-cage armatures are, therefore, widely employed in the induction motors used in textile establishments.

The advantages of the direct drive in textile work are considerable. One of the most important is the simplicity of the power installation, which requires no shafting, pulleys, belts, ropes or elaborate gearing. As the actual amount of power required to drive each individual textile machine is small, the friction losses in the shafting and belts of a group-driven system become of great relative importance. With the individual drive a better subdivision of power is possible and the elimination of long lines of distributing shafting does away with losses in transmission, which, in a large mill, foot up to an unpleasant total in the course of a year's run. Overtime work can be carried on at any machine or number of machines with the direct drive, and at almost nominal expense for power in comparison with the cost of thus operating with a belted system. Another great advantage is found in the more uniform speed of the direct drive, which results in an increase in the rate of production, with fewer brakes and a better grade of goods. The goods are further improved by the better light secured through the absence of belts and shafting, and the elimination of oil and dirt common to belted installations is perhaps one of the greatest advantages of the individual drive. A single spot caused by a drop of oil falling upon a piece of silk or velvet in the process of weaving is enough to ruin the goods, and on this score alone it is safe to say the use of direct-connected motors is often entirely justified. The production rate of looms has been shown by actual test to be increased from 5 to 7 per cent when the individual drive is employed. In one installation the worst loom in the mill was equipped with a direct-connected motor. When belt-driven this loom gave so much trouble that no operator was willing to remain and work with it. After the motor was applied it was found that the loom turned out as much work as the best machines in the mill, and the attendant in charge became unwilling to leave the loom for any other.

With direct connection, in case an accident happens to any loom or to any part of the driving mechanism, only one machine is rendered inoperative, whereas, with the usual belt-driven arrangement, if the main belt breaks, or any of the shafting becomes disarranged, the entire section, comprising many looms, has to be shut down, with a resulting reduction of output. In new plants the absence of shafting and belts permits a material reduction in the cost of the building construction.

The idea has been widely held that because the first cost of a direct-connected electrical outfit is often almost double the investment required for the group-driven system, it will not pay to install the former scheme. It is easy to demonstrate the falsity of this conclusion by drawing upon figures from actual practice. In a certain mill which manufactures cotton duck the weave room was originally equipped with a 65-h.p. induction motor and shafting, from which the looms were driven by belts. The first cost of the motor was $985; the belts and shafting cost $1970, making the total investment $2955. Not long since the individual drive was substituted, in the form of 10 1-h.p. and 64 ½-h.p. Westinghouse type C induction motors. The ten larger motors cost $760 and the smaller ones $4150, making a total of $4910. The difference in the investment was, therefore, $1955 in favor of the group drive. However, tests showed with the individual drive a saving of 15 horse-power otherwise lost in belt and shafting friction, which would cost $375 per year at the moderate steam plant production cost of $25 per horse-power per annum. The interest on the excess cost at 5 per cent came to $98 per year, leaving a saving of $277 per year in favor of the individual drive. Simply on the basis of annual power saving, the latter drive, therefore, will pay for itself inside of 7 years, to say nothing of the money value of the increased production resulting.

In another recent case the first equipment of a spinning room was a 65-h.p. motor costing $985. The belts and shafting came to $798, making $1779 for the installation. This was replaced by 18 motors rated at 3 horse-power each, representing an investment of $1830. The annual saving in friction loss was 7 horse-power, or $175 at $25 per h.p.-year. In this instance the cost of replacing the old equipment with direct-connected motors was so slightly in excess of the original investment that even if there had been no saving in friction losses it paid to make the change on account of the general advantages of the direct drive. The second-hand value of the original installation was not figured and the difference in efficiency between the large motor and the several smaller units was not considered of sufficient importance to affect the decision. In each case the wiring came to practically the same cost. When speed variations are desired with direct-connected equipment, the present practice provides for the change by altering the motor pinion, moving the motor backward or forward to correspond with the change in gear. Automatic stops are provided to bring the motor to a standstill immediately in case a thread breaks, and in the later direct-connected equipments the motor is controlled through the shipper handle in order that the attendant shall be able to operate his machine in the same manner as though it were belt-driven.

Hydro-Electric Development in Italy.

THE 36,000 VOLT TRANSMISSION PLANT AT MONTEREALE-CELLINA.

BY L. RAMAKERS.

Among recent installations for the generation and transmission of electric power the hydro-electric plant at Montereale-Cellina, Italy, which supplies electricity for lighting and power purposes to Venice and the surrounding districts, is worthy of attension. Power to operate the generating units is taken from the Cellina, a river having its source in the Carnic Alps and delivering at its lowest ebb 30,000 litres of water per second. Many difficulties were encountered in the construction of the plant, which has cost more money and labor than any other in Italy. A masonry dam across the narrowest part of the river serves the double purpose of raising the water level at the intake and creating a reservoir of about 300,000 cubic meters at periods of very low water. Four large sluices regulate the overflow and are operated by electric motors fixed on the bridge which crosses the whole construction. The intake proper is formed by two rectangular mouths, 2 meters wide by 3 meters high, adjustable by sluices. A canal, 4328 meters long, partly cut in rock, supported by a series of walls, arches and galleries, completed on the river side by a wall with an external slope, and cemented inside, leads from the intake to the opening of a large tunnel. This tunnel is 1073 meters long and has the same gradient and section as the canal. It is cut entirely in califerous rock and empties into another canal leading to a small lake having an area of about 2400 square meters, in which matter in suspension is allowed to settle before the water reaches the turbines. Six large penstocks lead from this lake to the main generators, and a seventh penstock is divided into two branches for small exciter turbines.

FIG. I.—INTERIOR OF THE GENERATING STATION.

The main station is situated near the village of Malnisio. This consists of a central building with two projecting wings and an annex on the west side. The eastern portion contains a workshop for repairs, warehouses, offices and living rooms for the engineers and workmen. The main generating units occupy the entire central portion. In the western part, in a room leading from the turbine room, are the switchboard, switches and lightning arresters, and the step-up transformers are located in the annex. The turbines discharge water at a level of 281 meters. The level of the dam is 339.64 meters, so that the head available is 58.64 meters. With a discharge of 20 cubic meters per second, which represents the minimum power, there is available 15,600 horse-power, with a maximum of 18,900 horse-power.

Inward-flow reaction turbines, having a single wheel and horizontal shaft and two lateral discharges (one on each side), are installed to utilize this power, the smaller turbines for the exciters having a single discharge. At present there are but four turbines installed, but provision is made for six, it being intended to use one as a reserve. Each turbine consumes 4500 litres of water per second and develops 2600 horse-power at 315 r.p.m. The turbines for the exciters, which are smaller but similar in construction, are three in number and develop each 200 horse-power at 500 r.p.m. The larger turbines are direct-connected through rigid couplings to three-

phase alternators furnished by Brown, Boveri & Co.

The alternators have fixed armatures and rotating fields. The exciting current can be adjusted so as to vary the voltage at the terminals from 3600 to 4800 volts. The normal tension of the alternator with non-inductive load is 4000 volts at a frequency of 42 cycles. The commercial efficiency of the main units under full inductive load is 95 per cent. The fall of potential between no load and full load with the usual speed and exciting current is 5 per cent of the normal voltage with non-inductive load, and 16 per cent with an inductive load.

Direct current for exciting the fields of the alternators is provided by dynamos direct-coupled to the smaller turbines. These dynamos are shunt-wound machines with six poles and drum armature, and generate current at a potential of 200 volts. The commercial efficiency of these machines at full load is 93 per cent. Three alternators are at present capable of carrying the load, the output from two being transmitted, while the output of the third is used for local service.

Transformers of the single-phase type are used in preference to those of three-phase in stepping up the potential for transmission, since it is desirable in case of large units to limit as far as possible the damage and cost of repairs in case of an accident, and since it is also advantageous to heighten the tension when necessary by altering the connections from the mesh to

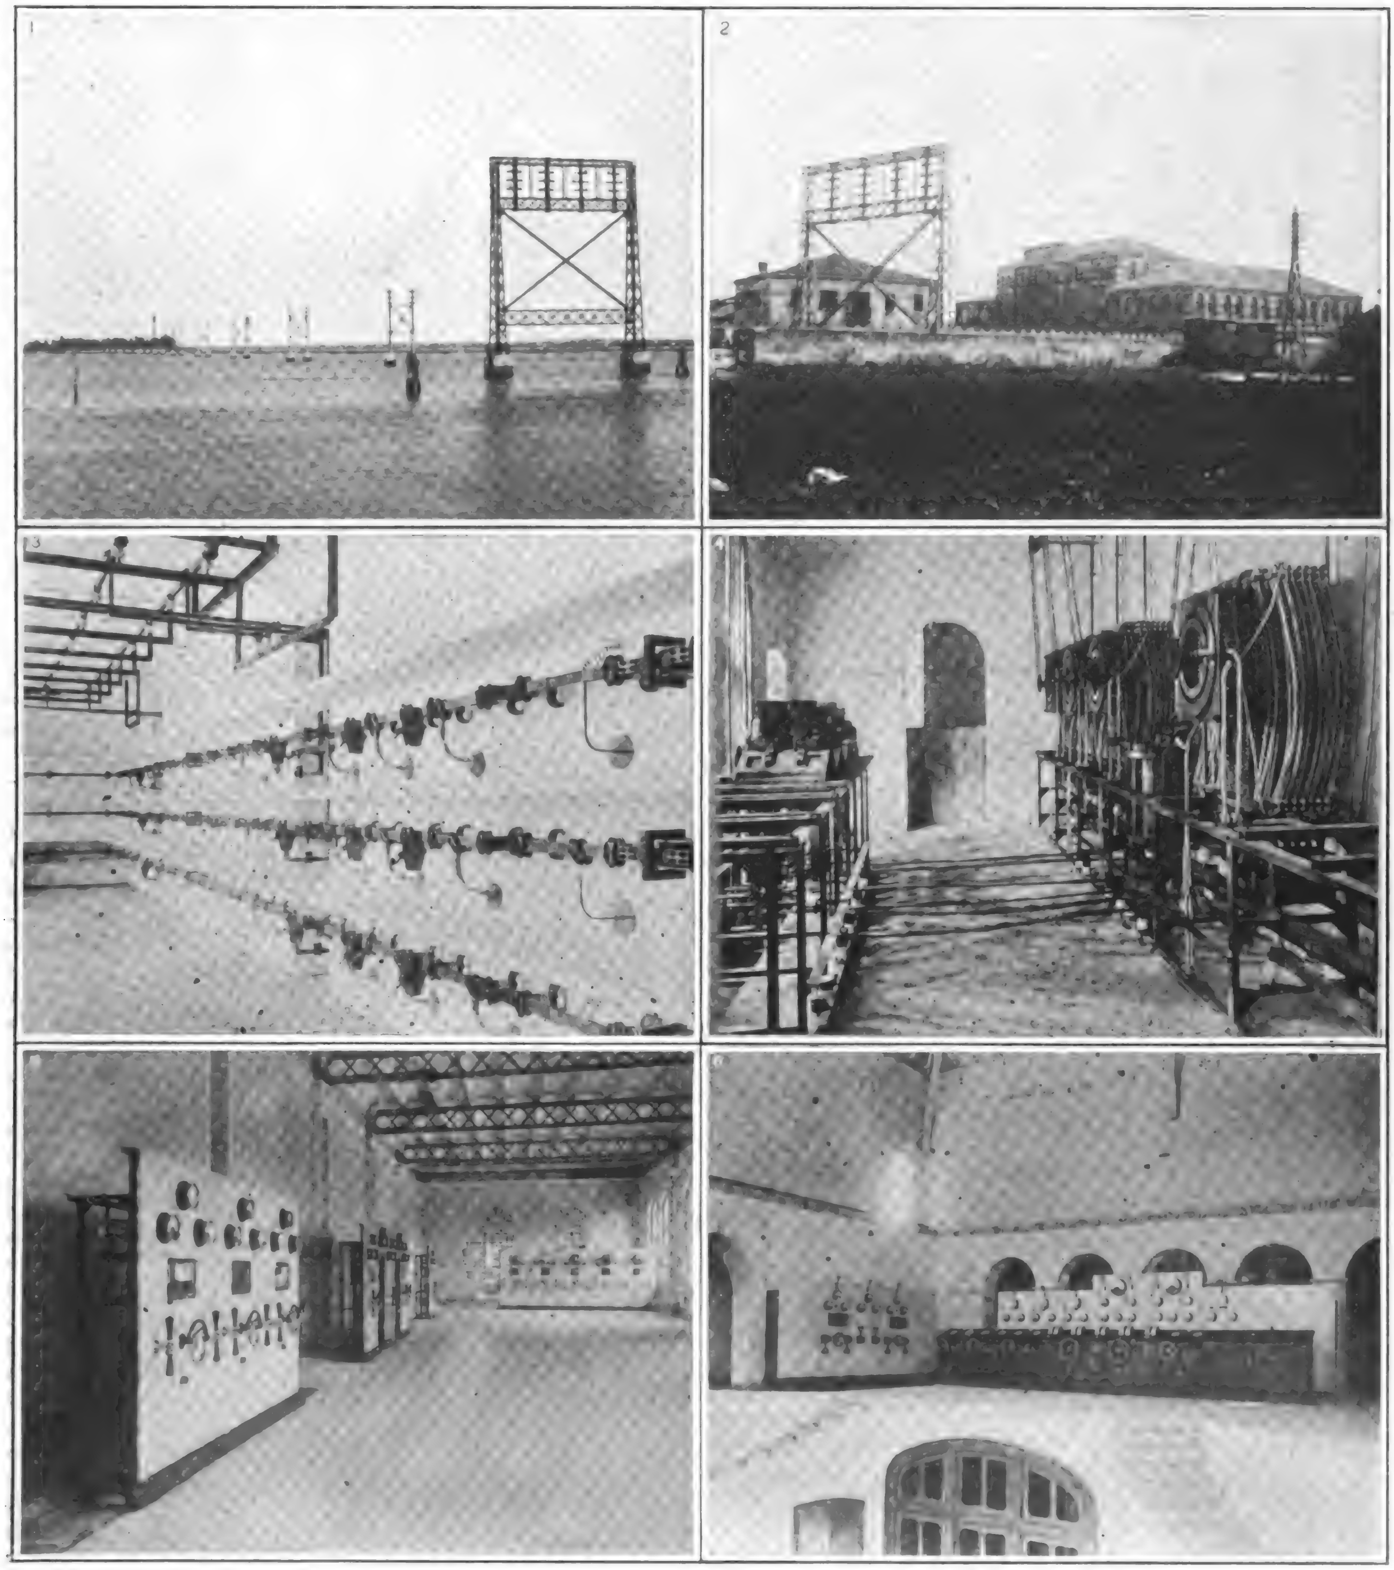

FIG. 2.—MONTEREALE-CELLINA TRANSMISSION PLANT.

the star system. The transformers have been chosen with reference to the capacity of the line they are intended to eventually feed. When the installation is complete the transmission line will consist of four groups of three conductors each and will carry a load of 12,000 kilowatts. The transformers installed are of 1000 kilowatts capacity, so that each bank of three will feed a group of three wires. Normally each bank of transformers will be connected with a given group of wires without any connection in parallel on the high-tension side with the other groups, so that in case of a lightning discharge on the line, only those transformers connected with that particular line will be affected. Fifteen transformers will be ultimately installed, the fifth bank of three being held in reserve in case of accidents to any of the other banks. The ratio of transformation in these transformers is 7.5 to 1, so that with a primary voltage of 4000 the secondary tension will be 30,000 volts, which will be increased to 36,000 volts, with a maximum primary voltage of 4800 volts. The commercial efficiency of the transformers with unity power factor is guaranteed to be 98 per cent. The alternators are separately connected to a system of collecting bus-bars in the shape of a closed ring which is divided into multiple sections by knife switches. This ring of collecting bars is in turn connected with the various banks of transformers, so that it may be considered as divided into two parts—one in which the energy comes in and the other in which the energy goes out—and the integrating wattmeters are placed between the two.

The working transformers are connected directly to the lines through lightning arresters, while the spare transformers are connected to a system of auxiliary bars which can also be used to place the transformers in parallel on the high-tension side if this is desired. The switches are all of the oil-break type, the 4800-volt switches being double-break and enclosed in an oil compartment, while the 3600-volt switches are of the six-break type and enclosed in three separate oil compartments, one for each phase. All the switches are operated from a distance by means of levers controlled by hand from the switchboard. Automatic circuit-breakers are installed to open the circuit as soon as the current reaches a predetermined limit. The lightning arresters are of the Wurtz type with four self-induction coils and with four paths to earth by means of the usual series of non-arcing metal cylinders. Before discharging through the Wurtz apparatus, however, a discharge may find its way to earth through a double-horn lightning arrester and also through a lightning arrester of the Gola type.

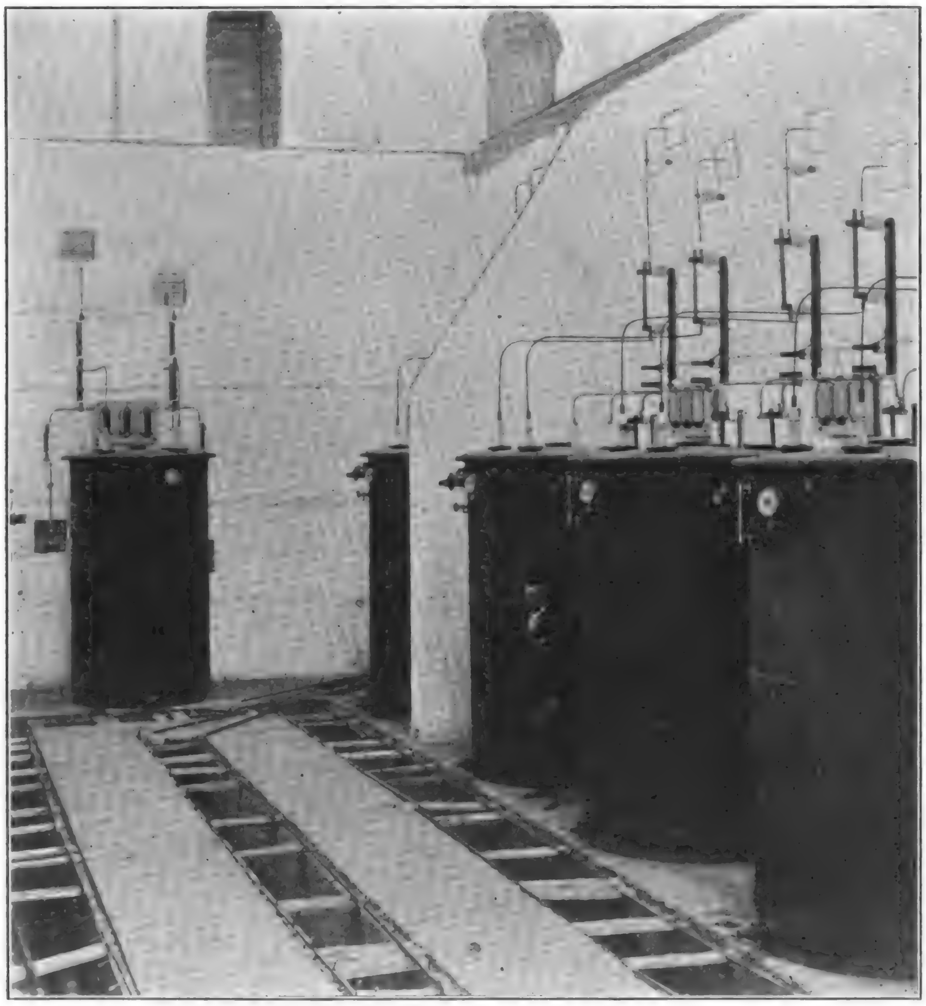

FIG. 7.—STEP-UP TRANSFORMERS IN MAIN STATION.

Beneath the engine room and situated in large tunnels are the conduits for the 4000-volt circuits and the 200-volt circuits of the exciters. These conduits, which are widely separated, lead to one end of the building and pass thence to the switchboard. This is divided into two distinct parts, one controlling the direct current and containing switches, collecting bars and rheostats for the field circuits of the alternators, all of which are worked from the upper platform; the other for the 4000-volt, three-phase current. A masonry partition is provided for each alternator circuit. This partition is divided into two parts, the lower part for the automatic switch worked from the upper platform, and the upper part for the measuring transformers for the switchboard instruments. A similar arrangement prevails for the circuits connecting the collecting bars with the transformers. The adjoining room is used exclusively for the rings of collecting bars, which are fitted along the walls and on the ceilings and are separated from each other by slabs of reinforced concrete. After passing to the switches, the conductors connecting the rings with the transformers descend to the lower floor, where in groups of three they pass through the transformer room to the annex. The 36,000-volt conductors pass above these. The whole complicated installation is controlled from the platform of the switchboard which is at one end of the room and contains a central board and table for working the switches and two lateral boards. The central board carries the ammeters, voltmeters, wattmeters and relays for the automatic switches, and the ammeters and integrating wattmeters connected between the two halves of the bus-bars. The working table carries the hand wheels controlling the switches and the rheostats for the field circuit, the ammeters and exciting switches, the voltmeters and phase indicators. At present there are seven main switches installed, two of which are automatic. After passing through these and the transformers for the ammeters, the conductors go to an upper story where six rows of lightning arresters are located, and pass out of the station and overhead by a double row of poles to Venice. The mean distance between the poles is 55 meters, and in the lagoon district about 4 kilometers of the line is supported on iron lattice work. The current arriving at Venice has a potential of about 27,800 volts, the transmission loss being 7.35 per cent on unity power factor, and 12 per cent with a power factor of 75. The current is stepped down at Venice to 6200 volts through nine transformers of 900 kilowatts capacity each. These transformers are similar in design to those in use at the generating station. The lightning conductors and switchboards in use at Venice are also similar to those used at the generating station, and the same may be said regarding the distribution of the various apparatus. A similar system of rings of collecting bars is also used. Two additional rings are installed as reserve, and it is intended to eventually use these to enable the lighting and motor loads to be separated. Sufficient space has been provided for fourteen outgoing leads, although at present only nine are installed—six for motor service and three for lighting

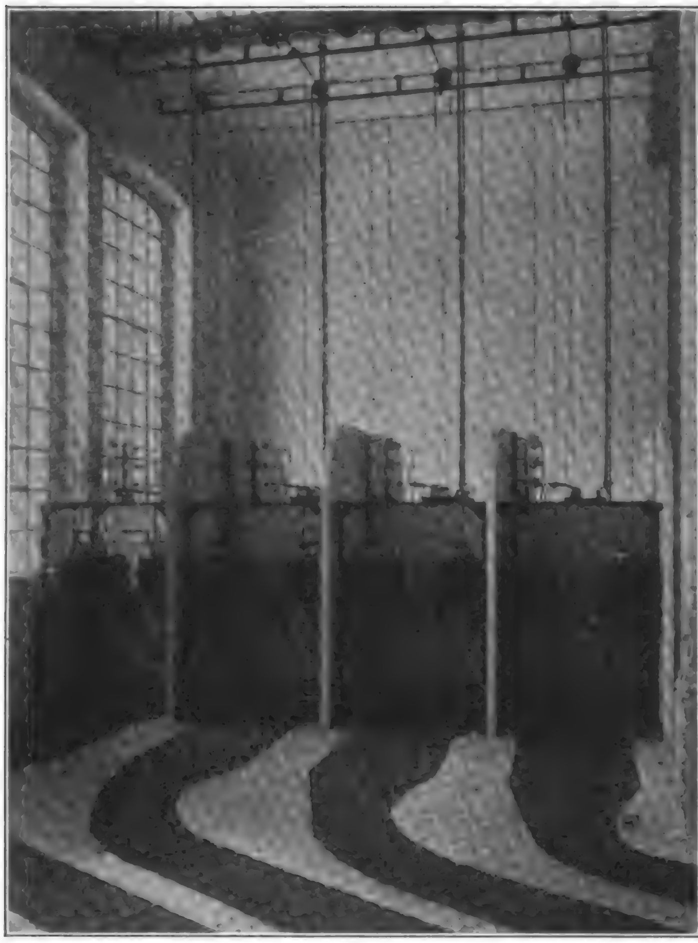

FIG. 3.—SWITCH GEAR IN SUB-STATION AT VENICE.

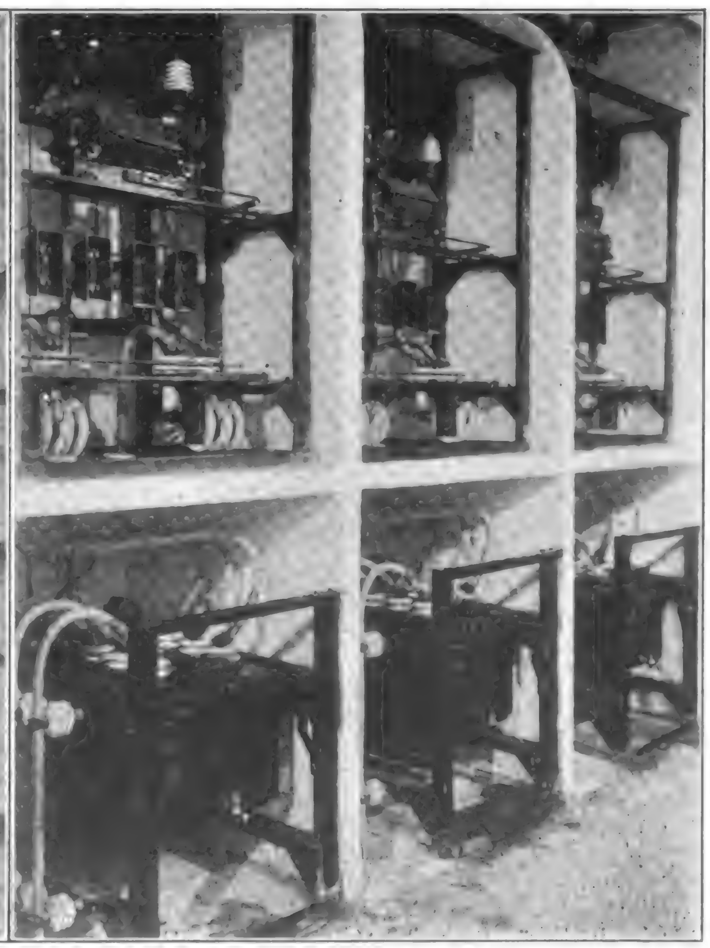

FIG. 6.—INSTRUMENT TRANSFORMERS AND GENERATOR SWITCHES.

service. These leads are fitted with Wurtz lightning arresters combined with cut-outs and liquid resistances. The drop of potential in the lines in the urban service is about 3 per cent, and for this reason a tension of 6000 volts is maintained at the main supply stations. The lines are all placed overhead, and where they cross the canals the wires are kept at a height of at least the field circuits of the alternators, all of 18.50 meters above high-water level. Of the six power leads, two go to the Arsenal, two to the Dorsodura and Santa Croce, and two to the Isola della Guidecca, the main center of Venetian industry. All these leads are of bare copper wire. The leads for the lighting service are the property of the community. These are of insulated copper wire and traverse the city in various directions, converging at the electric station of S. Luca, where the tension is reduced from 6000 volts to 2000 volts, so as to feed the transformer leads of the existing lighting plant, which operates at this tension. Each of the three new lines intended for the lighting service may be divided into various parts between the sub-transformer stations through oil switches. Thirty sub-stations are to be installed. These will be fitted with transformers of

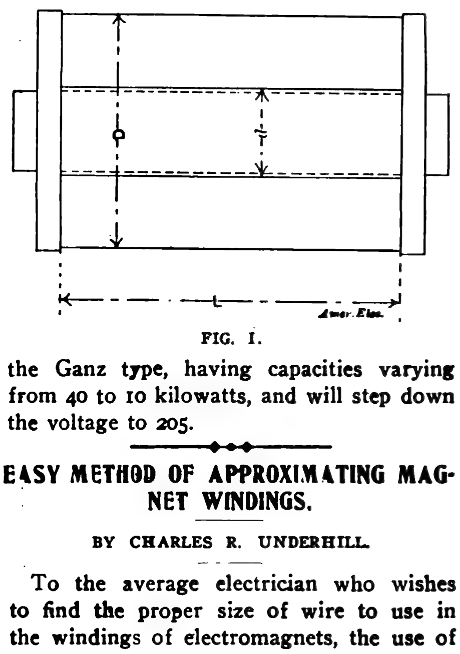

FIG. 1.

the Ganz type, having capacities varying from 40 to 10 kilowatts, and will step down the voltage to 205.

EASY METHOD OF APPROXIMATING MAGNET WINDINGS.

BY CHARLES R. UNDERHILL.

To the average electrician who wishes to find the proper size of wire to use in the windings of electromagnets, the use of winding formulæ is often confusing. The graphic system, however, not only eliminates the necessity of formulæ, but makes the whole operation clear and simple.

In describing each of the accompanying charts actual cases will be cited to facilitate following the methods employed. No reference will be made to the theory of the electrical constants or how the charts are made.

In order to find the proper size of insulated copper wire to fill a given winding

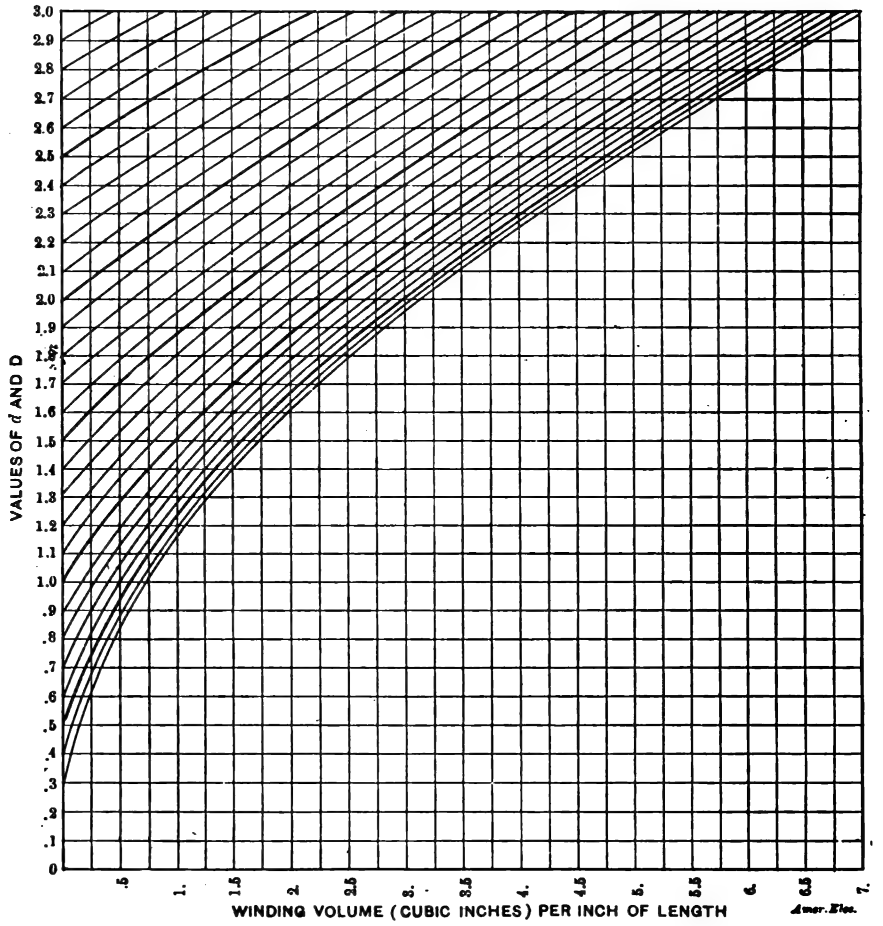

FIG. 2.

space, and have a given resistance, it is necessary to know the cubical contents of the bobbin, or the actual volume of the winding space in cubic inches, and the ohms per cubic inch for the various sizes of copper wire with various increase in diameters due to the insulation. Therefore, if the winding volume of a bobbin be 2 cubic inches, and the ohms per cubic inch 250, the resistance of the winding would be 500 ohms. It is very important that the actual available winding space should be taken; that is, the space which is left after the bobbin is properly insulated.

As most windings for electromagnets are wound upon a round core or tube, the round type of bobbin will be assumed throughout this article. This bobbin is illustrated in Fig. 1.

Referring to Fig. 2, the winding volume (in cubic inches) per inch of length of winding is found by following the curved line, which starts from the value of d, the inside diameter, to where it intersects the horizontal line corresponding to the value of D, the outside diameter, and then tracing vertically downward.

As an example, the outside diameter of a winding is 2 inches and the diameter of the insulated core, d, is .9 inches. Following the curve which starts at .9 it will be found that it intersects the horizontal line corresponding to 2 at the vertical line corresponding to 2.5 cubic inches per inch of length of winding. If the length, L, be 3 inches the volume of the winding will then be $2.5 \times 3 = 7.5$ cubic inches.

The charts, Figs. 3 to 8, show the ohms per cubic inch for various diameters of

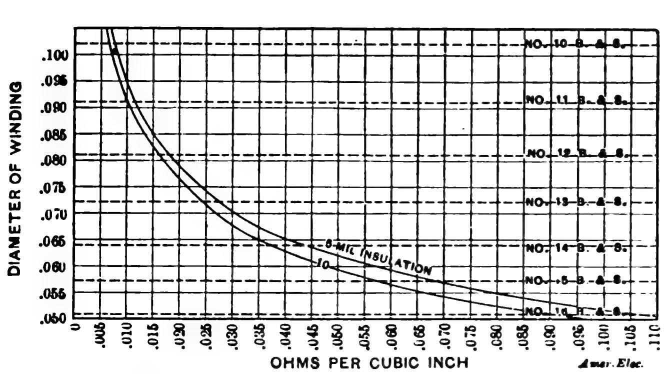

FIG. 3.

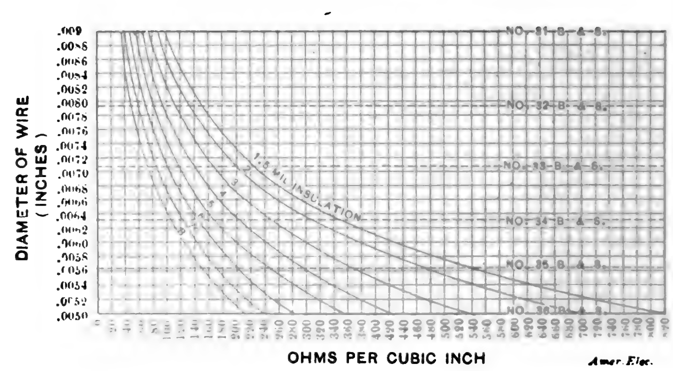

FIG. 7.

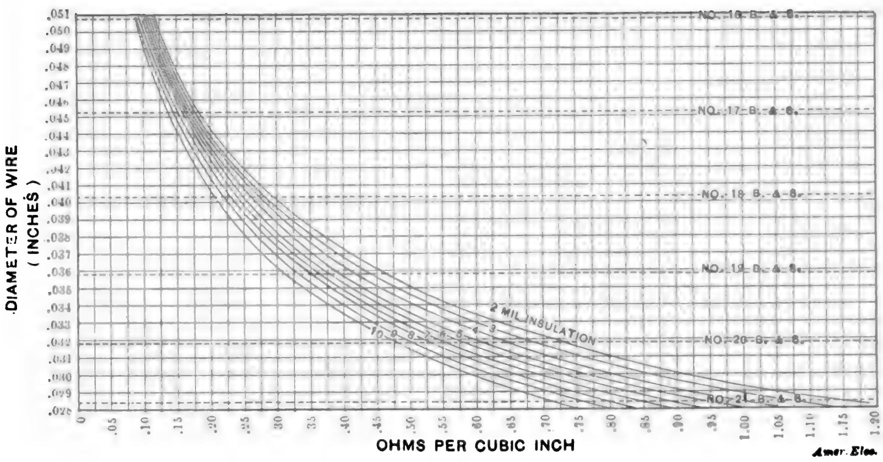

FIG. 4.

copper wire irrespective of the gauge number, with various increases in diameter due to insulation. A 4-mil increase means that the diameter of the insulated wire measured over the insulation, is 4 mils greater than the diameter of the bare copper wire. For convenience, the different sizes of wire of B. & S. gauge are shown in dotted lines, in positions corresponding to their diameters.

Although the increase in diameter due to insulation on the wire may vary with different manufacturers, the increase in diameter due to single silk insulation varies from 1.5 mils to 2.5 mils, and from 3 mils to 5 mils for double silk insulation. For cotton-covered wire the increase in diameter varies from 4 to 5 mils for single cotton, and from 8 to 10 mils for double cotton insulation. In any event it is well to caliper the insulated wire with a ratchet stop micrometer, to ascertain the increase in diameter due to the insulation.

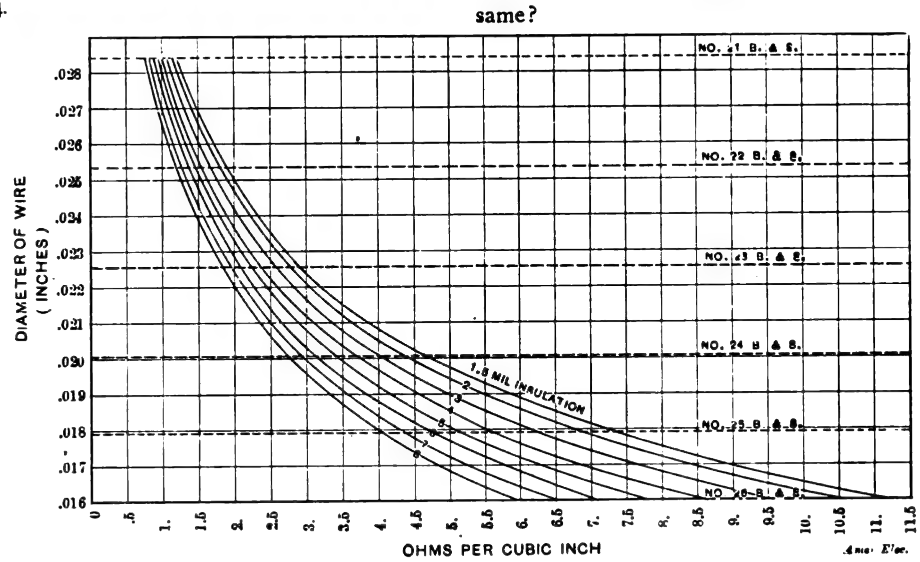

FIG. 5.

As an example of the use of these charts, refer to Fig. 5 and assume that an insulated copper wire is desired which shall have a resistance of 4 ohms per cubic inch when wound on a bobbin. Tracing vertically upward from 4 it will be found that this result is obtained with a wire .018 inch in diameter, with 8 mil insulation, or with a wire .0184 inch in diameter with 7 mil insulation, etc., the largest diameter of copper being obtained with 1.5 mil insulation, the diameter of the wire being .0208 inch.

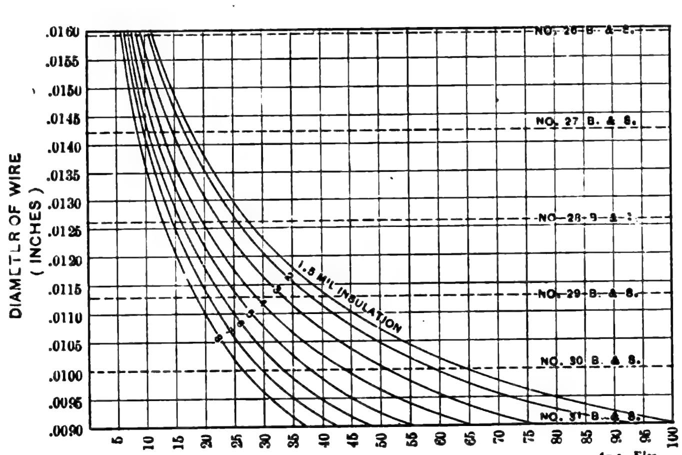

FIG. 6.

Therefore, if the 8-mil insulation be used a No. 25 B. & S. wire would be used, while with even 3-mil insulation a No. 24 B. & S. wire would suffice, this latter wire being desirable.*

Likewise, if the bobbin will contain 1.24 cubic inches of wire, and a resistance of 5000 ohms is required, it is evident that an insulated wire with 4050 ohms per cubic inch would satisfy this condition, and by referring to Fig. 8 it is found that No. 40 B. & S. wire with 1.5-mil silk insulation will meet this requirement.

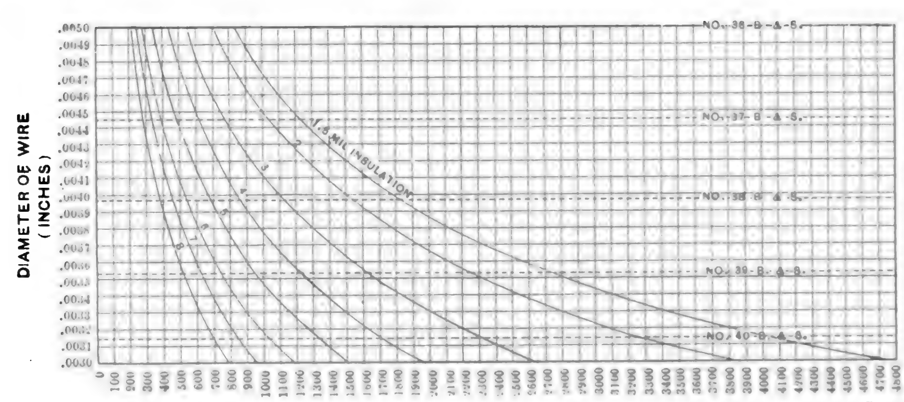

FIG. 8.

The following cases will aid in approximating coils:

Case 1.—Given a bobbin with dimensions $D = 3$, $d = 1.5$, $L = 3.25$, resistance 500 ohms, to find proper size of wire with 4-mil single cotton insulation.

Referring to Fig. 2 it will be found that there will be 5.25 cubic inches per inch of length of winding which makes the volume of the winding $5.25 \times 3.25 = 17.06$ cubic inches. The ohms per cubic inch will then be $500 \div 17.06 = 29.3$. Reference to the charts will show that the nearest copper wire with 4-mil insulation will be No. 29.

Case 2.—If No. 30 B. & S. 4-mil insulated wire were used in the above case and the resistance were 500 ohms as before, what would be the outside diameter of the winding, all other dimensions remaining the same?

Referring to Fig. 6, it will be found that the ohms per cubic inch are approximately 44 for No. 30 B. & S. wire with 4-mil insulation. Therefore, the volume of the winding must be $500 \div 44 = 11.4$ cubic inches, and since the length of the winding is 3.25 inches the winding volume per inch of length will be $11.4 \div 3.25 = 3.5$. Referring now to Fig. 2, and tracing vertically upward from 3.5 to the point where this line intersects the curve which starts from 1.5, the outside diameter, D, is found to be 2.58 inches. Therefore, wind to a diameter of 2.58 inches, with No. 30 B. & S. wire with 4-mil cotton insulation, and the resistance will be approximately 500 ohms.

While other cases may be worked out for any given diameter of wire and any increase due to insulation, the two cases above given are the most used, and after a little practice these problems may be very easily worked out.

* See "Comparison of Common Methods of Coil Windings," AMERICAN ELECTRICIAN, May, 1905.

ELECTRIC CONTRACT WORK.

BY LOUIS J. AUERBACHER.

Wiring System.

Before laying out the wiring system for a building, it is necessary to ascertain whether power will be supplied from the central station, or whether it is the intention of the owners to install a private plant to generate electric power. If the latter plan is decided on, a two-wire multiple system should be installed. Fig. 1 shows the general scheme of such a system in connection with a dynamo.

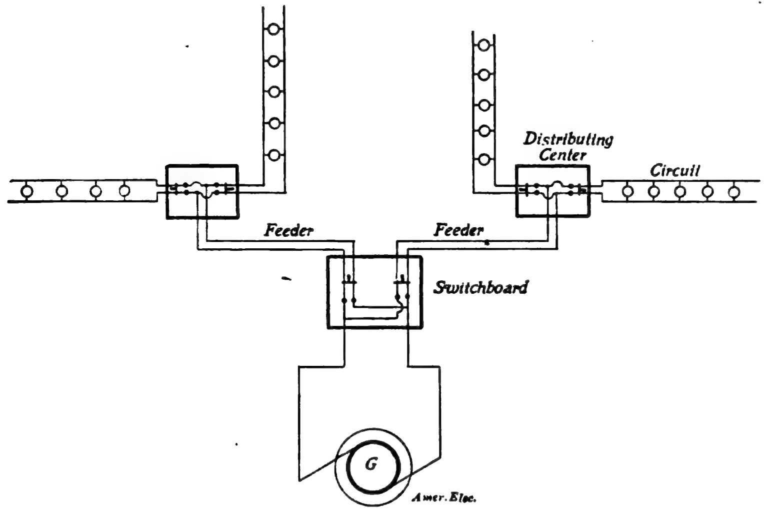

FIG. 1.

Should the local illuminating company supply power as an auxiliary or breakdown service, as it called; this supply should be connected to the wiring system through a double throw switch. This double throw switch can also be used as the generator switch and the method of connection is shown in Fig. 2.

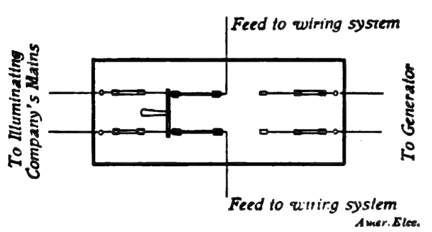

FIG. 2.

Should the auxiliary supply furnished by the local illuminating company, be brought in through a three-wire system, the connection at the switchboard would be made through a double-throw three-pole switch, as shown in Fig. 3. The side of the switch controlling the current from the plant is bridged as shown in the diagram.

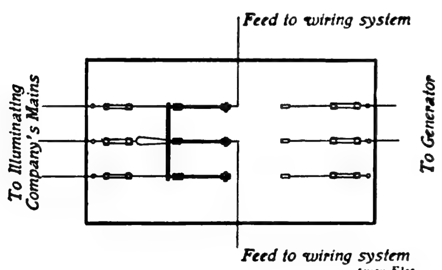

FIG. 3.

Should it be decided to use only the power from the local electric light company, the system in use must be ascertained before the general scheme of wiring is laid out. If a three-wire system is used the general scheme of wiring will be as shown in Fig. 4. When installing this system in a building it is best to put in the three-wire convertible system, or "three-wire two-wire," as it is sometimes called. The only difference between this system and the straight three-wire system is that the center, or neutral, wire of the mains and feeders should have a current capacity equal to the other two. The reason for this is that it allows the system to be readily changed over to a two-wire system for use in connection with a private plant. It sometimes happens that after using power from the local electric illuminating company for some time, conditions arise which make it expedient for the owners to install a private electric plant. If a straight three-wire system had been originally installed, the mains and the feeders when used on a two-wire system would not be heavy enough by 25 per cent., as the neutral wire of a straight three-wire system is the same in size as one of the two outer wires, and theoretically carries one-half the current or less.

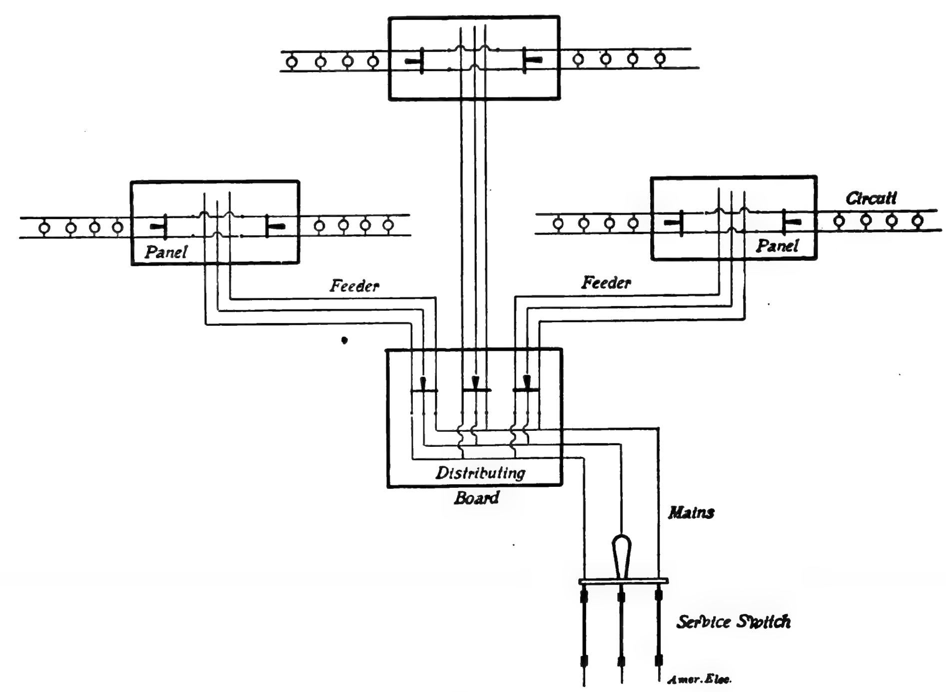

FIG. 4.

To change a regular three-wire system to a two-wire system would be expensive, since it would require the reinforcement of all mains and feeders by an additional wire.

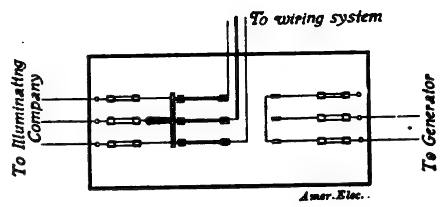

FIG. 5.

This wire would be connected with the neutral wire so as to make the capacity of the neutral equal to the sum of the other two (Fig. 6). On the other hand, if a three-wire two-wire system had been originally installed no change in the wiring system would be necessary. The only change would be at the service end of the switchboard, see Fig. 5, and the doubling of the size of the center fuses. It is, of course, possible to install a plant to operate a three-wire system, but such a plant is more expensive to install than one for a two-wire system, as it is necessary to add a balancer in connection with a 240-volt generator. This balancer set should have one-tenth the capacity of the plant. Such an equipment has its advantages when 240-volt motors and 120-volt lamps are connected to the system. With this plant no changes in the motors are necessary, whereas in a straight 120-volt system the motors would have to be changed from 240 to 120-volt machines.

The supply from the local illuminating company may be two-phase alternating, and if the load to be connected to such a system is small, say not over 10 kilowatts, the general practice is to wire for a straight two-wire system, using one phase of the current for a supply. In larger installations power is taken from both phases and balanced the same as a three-wire system. A

four-wire main, or feeder system can be used (see Fig. 7), in which each set of two wires carries one-half the current, or three wires can be used as in a three-wire system. The difference between the two is that in a three-wire, two-phase system the

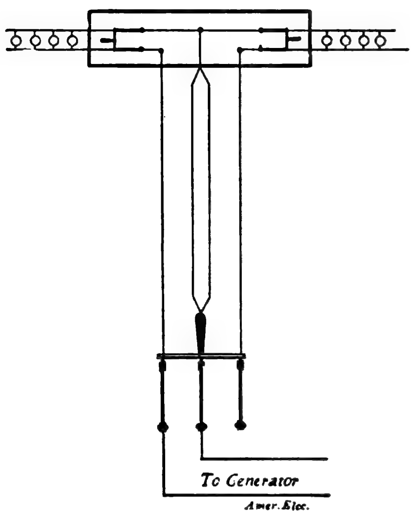

FIG. 6.

central wire should have 1.8 times the capacity of one of the outside wires. It should be always borne in mind that if any alternating system is used in connection with iron pipe or conduit all the wires of a circuit must be placed in one pipe to avoid induction. In a two-phase system the two wires of each phase can be placed in a pipe. This matter is fully covered in the Underwriters' Electric Code.

As soon as a decision is reached as to the particular system to be used, the contractor may lay out the mains, feeders and branches of the wiring system. The outlets are first located and then the distributing centers. There is no fixed rule or plan by which to go, but the current density and source of supply are the main points to be considered in locating these centers. Another point which must be taken into consideration is the construction of the building with relation to runways and shafts, which provide easy runs for feeders.

In Fig. 8 is shown a floor plan of a loft building, in which the outlets are distribut-

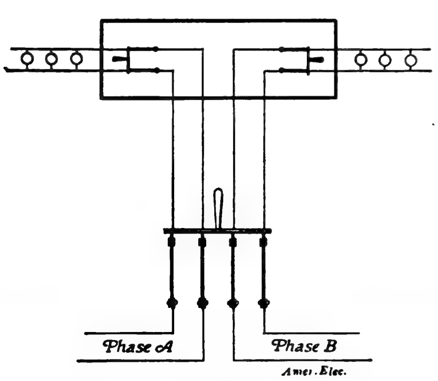

FIG. 7.

ed evenly. The source of supply is in the front of the building, and an elevator shaft is located near by. This shaft is an ideal place for placing the feeders, and the panel is shown near the shaft. In many buildings it is impossible to run the feeders up the shaft, owing to the construction of these. In such cases the feeders are run up the side walls, or in specially built pipe shafts. Feeders and panels should be located at current centers.

Panel-boards in loft buildings or in any building requiring 8 to 10 circuits to a floor should be distributed one to a floor. In private houses it is sometimes advisable to install only one panel for the entire house. This is good practice for a three-story house not requiring over twelve circuits.

In a building covering a large area it is often advisable to install two panels or centers to a floor, with two sets of feeders. It is advisable to keep circuit lengths down to 100 feet or less, and the judicious laying out of circuit centers will save many feet of wiring.

The feeder system for a building depends on many conditions. A good scheme is to draw an elevation of the building (Fig. 9) and note on each floor the current requirements. The best plan is to furnish a feeder for every floor, especially in large installations. In smaller installations one or two feeders are sometimes all that are required. Feeders for motors should be installed independent of the lighting feeders. In the case shown by Fig. 9 it will

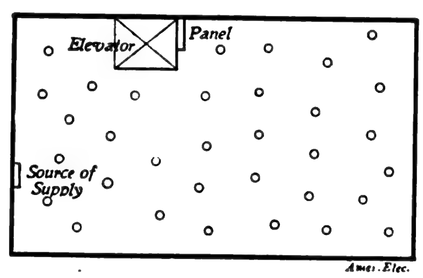

FIG. 8.

be seen that the basement and first floors require the most power. In such a case a feeder is run for these floors, and a sub-feeder from the basement to the first floor. It is not worth while to reduce the size of the sub-feeder unless the amount of current used on the sub-feeder is a small percentage of that used in the feeder. Another reason is that in changing the size of a wire the underwriters require a fuse to be inserted. This makes it necessary to install a larger panel with larger trim, etc., and the consequent expense easily offsets any gain made by installing a smaller wire.

Feeders needing over 2 in. pipe should not be used. It is better to subdivide them, especially if there are many bends or offsets, since two inch pipe is about the limiting size for economical handling.

The feeders should all radiate from a distributing panel, having a proper sized switch and fuse for each feeder. If the system of wiring is such that auxiliary power is taken from a local lighting company it is a good plan to have each circuit controlled by a double-throw switch so that in case of overload any circuit can be fed from the illuminating company's mains (see Fig. 10).

The main wires should start from the illuminating company's service, and these companies have their own requirements as to where the contractor is to wire from. Some companies make the contractor run a line outdoors, furnish switch and fuse and also meter-board and loop. Other companies do not. The contractor can easily ascertain the requirements by

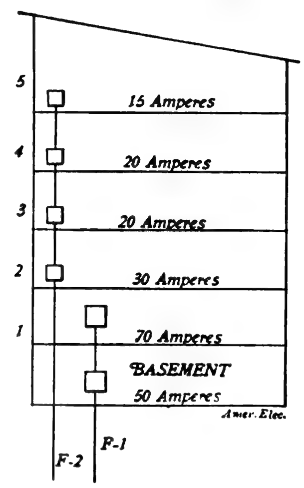

FIG. 9.

consulting the local inspector. The mains should be carefully installed and be of ample size. The contractor should urge his customer to provide for at least 25 per cent. more power than is at present required; and if future requirements are known, in a general way, the wiring for the ultimate load should be installed although the immediate requirements call for a much smaller wire.

The contractor benefits by this surplus, and can more readily obtain orders for additions which would perhaps not be considered if the mains had to be changed at considerable expense.

It is a good plan to run mains and feeders in iron pipe even though the circuit wiring is run otherwise. Since the former carry the main supply of current it is important to have them well protected as they usually run up side walls. The Board of Fire Underwriters make numerous restrictions against open or molding work on

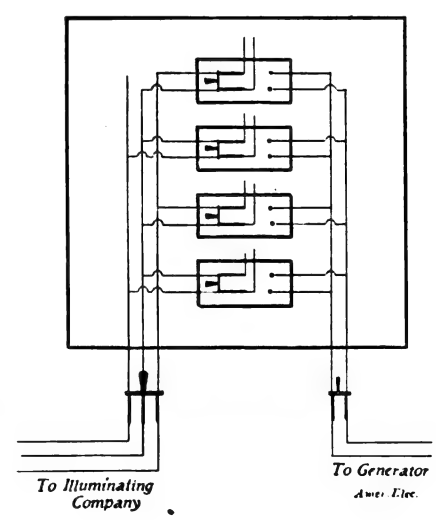

FIG. 10.

brick walls and require good protection, and this is an additional reason for piping the mains and feeders.

In laying out the branch circuit wiring it is not a wise plan to use up the Underwriters' circuit allowance of 660 watts.

Of course it will cost a little more to run ten 16-c.p. lamps or 500 watts to a circuit, but it is good practice. There are always small additional loads thrown on the wiring system and if the circuit capacity is not up to the limit additional outlets may be cheaply installed. From a business standpoint this plan has two sides. One is that the contractor can earn more by installing an extra circuit, while on the other hand the extra expense of running the circuit will often deter a customer from making any changes.

In runs over 100 feet on a 110-volt system No. 12 B. & S. gauge wire should be used, otherwise the drop of potential will

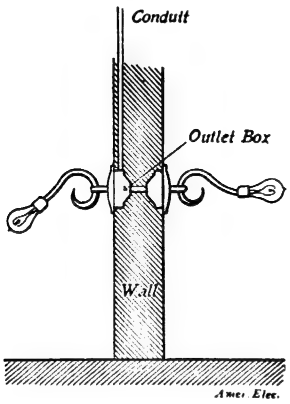

FIG. 11.

be too large. When locating side wall brackets in adjoining rooms these should be placed so that they will come back to back (Fig. 11). This saves much wiring.

In laying out a system of wiring, using moulding or knob and cleat work, the scheme of panels and feeds is the same. The difference is in the wiring appliances, which will be treated in subsequent articles.

In calculating the size of conductors, the following wiring formulæ will be found sufficiently accurate for general purposes:

FOR TWO OR THREE-WIRE, DIRECT-CURRENT LINES.

$$21.62\ D\ I \div v = \textit{cir. mils},$$

D being the distance in feet one way, I the current in amperes, and v the volts lost in the line.

Example.—Required, the size of mains to feed 100 16-c.p. incandescent lamps requiring 0.5 ampere each, the voltage of the circuit being 110, the distance 50 feet and the voltage drop 2 per cent.

$21.62 \times 50 \times 100 \times 0.5 \div (110 \times 0.02) = 24{,}523$ cir. mils = No. 6 B. & S. gauge wire, which is the nearest size.

In a 110-volt, three-wire system (220 volts between the outer wires) the current requirements should be calculated as equal to one-half that of a straight two-wire system. Consequently the three wires will each be one-half the size required on a two-wire system.

FOR ALTERNATING-CURRENT LINES.

$D\ W\ K \div P \times E^2 =$ *cir. mils* of each wire, D being the distance of transmission in feet one way, W the total number of watts to be transmitted, P the per cent loss in the line, E the voltage of the circuit, and K a constant, the various values for which are given in Table I.

TABLE I.

	Values of K				
Power factor	100	95	90	85	80
Single-phase	2160	2400	2660	3000	3380
2-ph. (four wire).	1080	1200	1330	1500	1690
3-ph. (three wire).	1080	1200	1330	1500	1690

Example.—What size of conductor will be required to transmit 100 amperes a distance of 50 feet on a two-phase system at a loss of 5 per cent, the voltage of the circuit being 110 and the power factor 90?

$100 \times 110 \times 50 \times 1330 \div (5 \times 110^2) =$ 12,091 *cir. mils* = No. 8 B. & S. wire, size of each wire.

In all calculations for the size of wire the Underwriters' requirements must be adhered to, so that if the calculated size for certain conductors is smaller than that allowed by the Board of Fire Underwriters, the size of wire given in the Code must be used.

Abstracts from Foreign Contemporaries

"Oriflame" Arc Lamp.– The chief difficulty with which makers and users of flame arc lamps have had to contend, is the rapid consumption of the carbon, so that the choice hitherto has been between comparatively short burning hours, or the employment of abnormally long carbons. In the "Oriflame" lamp, shown by Fig. 1 herewith and described in the London *Electrician*, the difficulty is overcome by the employment of a magazine capable of

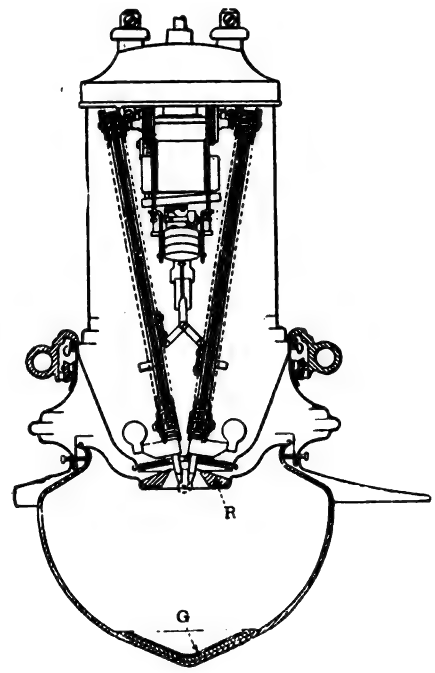

FIG. 1.—"ORIFLAME" ARC LAMP.

holding nine pairs of carbons each 12 inches long. These are of exceptionally small diameter; but the proportion of the total section taken up by the core is greater than in ordinary flame arc lamps. It has been found that within certain limits the greater the relative size of the flame-producing core, the greater the efficiency of the arc; but unfortunately the carbon is also more rapidly consumed. As, however, the lamp has a magazine to draw from, the carbons may be burned at a high rate and the arc is supplied with the requisite amount of potassium silicate and calcium fluoride, which produce flame and color respectively. Since the carbons are of smaller size, it is possible to use carbon of comparatively poor quality without impairing the steadiness of the arc. The cost of carbons need not therefore exceed one-fifth of a cent per lamp-hour in a nine-ampere lamp. Each pair of carbons burns five hours. The carbons are placed in two flat boxes inclined at an angle of 22 deg. They are put in at the back and are pressed forward by a pair of arms controlled by a spiral spring. Fig. 3 shows one of the magazines, the arms, *A A*, pressing against the carbons, *C*. The front carbon is forced from the magazine as shown, and is pressed forward by the stud, *S*, fixed on a chain, *B*. It is this chain which feeds the lamp. As shown, the stud, *S*, presses down the carbon as the lamp feeds by the travel of the chain. When this stud reaches the bottom the carbon is ejected and the next one takes its place, being pressed down as the chain travels by a second stud, *T*. One of the magazines is pivoted on the crown of the lamp, and this is swung by the controlling electromagnet to strike the arc, and also serves to regulate the length of the arc. When it reaches its extreme position, it closes an iridium

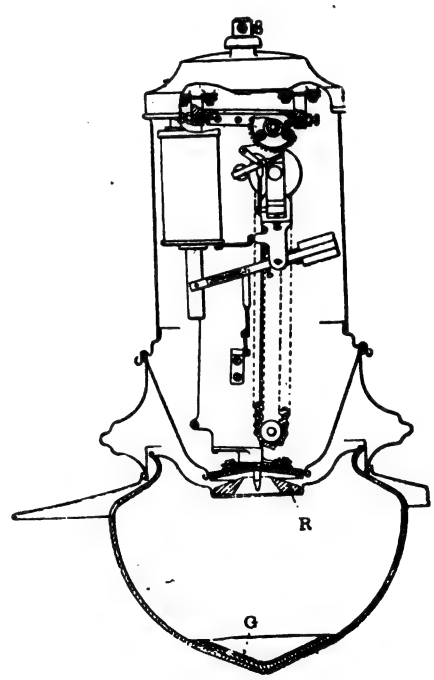

FIG. 2.—"ORIFLAME" ARC LAMP.

contact and sets into operation a make-and-break mechanism which actuates the sprocket wheels and feeds the chain onwards. The chain and rocking lever are mounted on knife edges so as to minimize

friction. The general arrangement of the lamp is shown by the engravings. The reflector, *R*, is provided to prevent the deposit of the products of combustion on the globe of the lamp. The reflector is made

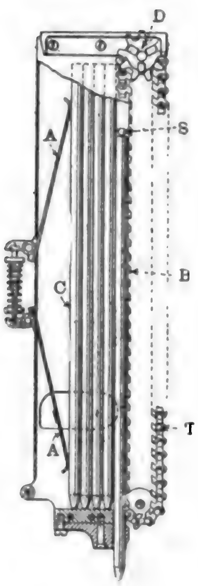

FIG. 3.

of porcelain in a copper spinning, and rests on the rim of the globe on three distance pieces. By this arrangement there is said to be an upward draught of air through the hole in the reflector and the products of combustion are deposited above. An ash tray, G, catches the short ends of carbons. The angle between the carbons is so small that no blow-out magnet is necessary. The voltage of the arc is 35, and allowing 5 volts for steadying resistance, etc., this represents 360 watts per lamp, the standard lamp consuming 9 amperes. The maker maintains that the light is far more intense than that given by the ordinary 500-watt lamp.

Tests of Tantalum Lamps.—Some interesting life and efficiency tests of tantalum lamps have recently been published by Prof. W. Wedding in the *Elektrotechnische Zeitschrift.* Fig. 1 indicates the distribution of light of the 25-c.p., 110-volt

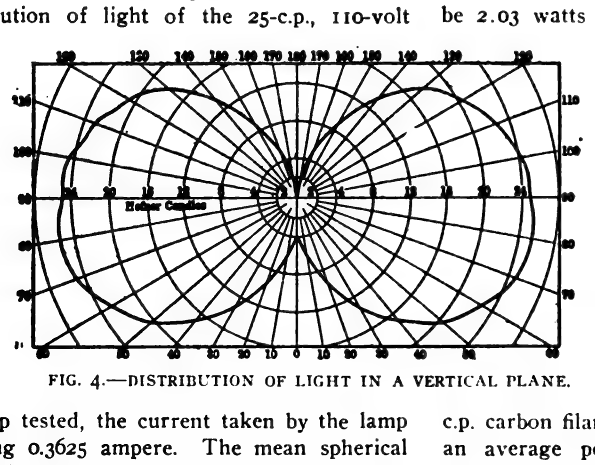

FIG. 4.—DISTRIBUTION OF LIGHT IN A VERTICAL PLANE.

lamp tested, the current taken by the lamp being 0.3625 ampere. The mean spherical candle-power was found to be 19.3 Hefner candles, so that the consumption per mean spherical candle-power works out at 2.065 watts, the consumption per candle-power in the horizontal plane being 1.6 watts. As regards the absolute efficiency of the lamp, the author calculates it to be less than 1 per cent, 0.866 of 1 per cent to be exact. Four new 25-c.p. lamps were tested until they collapsed. At the same time four ordinary filament lamps of 25 candle-power and 16 candle-power respectively were tested in the same manner. The average results are shown in Fig. 5, the four small crosses indicating the first breakage of filament in each of the tantalum lamps.

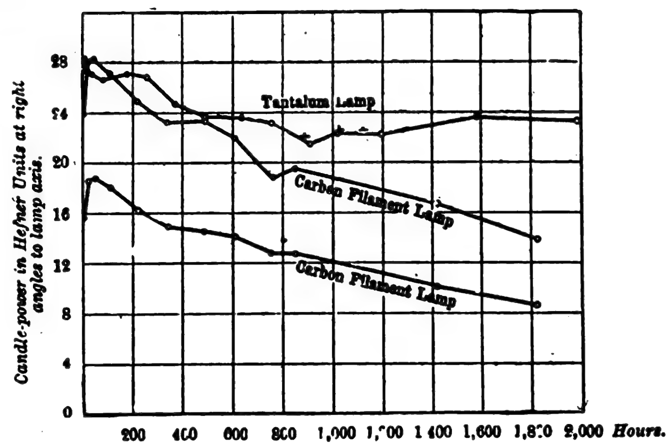

FIG. 5.—CURVES SHOWING THE VARIATION OF CANDLE-POWER WITH THE TIME.

As is well known, a breakage of the tantalum filament does not necessarily terminate the lamp's life; on the contrary, the broken ends generally make contact with some part or other of the filament, and the lamp continues to burn. But the breakages afterwards generally occur at shorter and shorter intervals, until the lamp becomes useless (see Fig. 6). At the commencement of the tests the average consumption of the four tantalum lamps per candle-power at right angles to the lamp axis was 1.68 watts. This figure dropped to 1.57 watts after seven hours and then rose to 1.60 watts after 17 hours, 1.62 watts after 37 hours, 1.67 watts after 85 hours, 1.64 watts after 179 hours, 1.66 watts after 256 hours, 1.79 watts after 370 hours, 1.89 watts after 637 hours, 2.04 watts after 905 hours, and 1.94 watts after 1,582 hours. The power consumption of the last lamp which survived, measured after 1,989 hours of burning, was found to be 2.03 watts per candle-power. The 25-

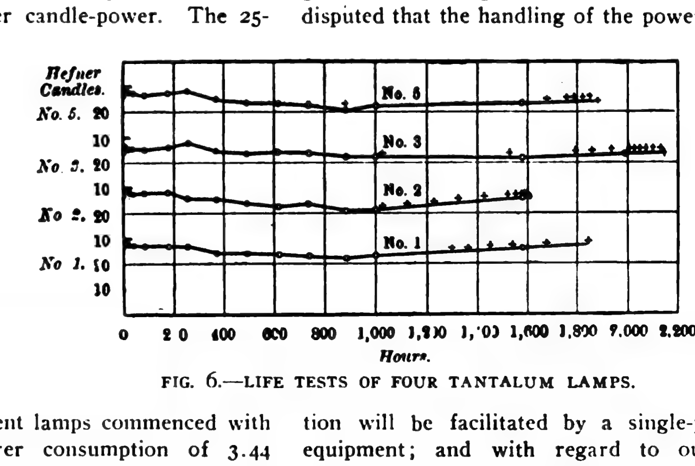

FIG. 6.—LIFE TESTS OF FOUR TANTALUM LAMPS.

c.p. carbon filament lamps commenced with an average power consumption of 3.44 watts. After 21½ hours this figure had dropped to 2.79 watts, after 110 hours to 2.94 watts, after 344 hours to 3.36 watts, after 609 hours to 3.52 watts, after 850 hours to 3.85 watts, after 1420 hours to 4.38 watts, and after 1826 hours, finally, to 5.25 watts. Similar figures were obtained for the 16-c.p. lamp—viz.: 3.23 watts per candle-power at the start, 2.81 after 21½ hours, and 5.44 after 1826 hours.

Single-Phase vs. Polyphase Transmission Lines.—H. S. Watson contributes to the London *Electrician* a short article on this subect. In spite of the great success of three-phase alternating-current systems, signs are not wanting that electrical engineering opinion may yet return to the almost discarded single-phase system. The advocates of single-phase have conceded to the three-phase system a saving of 25 per cent in the copper of the transmission lines; and it is to this supposed disadvantage of the single-phase system that the author draws attention. The relative copper efficiency depends entirely on the point of view from which the question is looked at. If a 10,000-volt single-phase system is compared with a three-phase system having the same voltage between its lines, the latter system, of course, has the lower copper cost for the same efficiency. But this is not a fair basis of comparison when an overhead line is in question. The basis of comparison should be that the insulation between any one line and earth shall be the same. The insulators are the determining factor. The author shows mathematically that on this basis an equal power can be transmitted with the same efficiency over a single-phase as over a three-phase system if the weight of copper is the same. It becomes a question with the author whether with overhead transmission it is better to erect a single-phase or a three-phase installation; and it would appear that there is some point at which the first cost in the two cases is equal. This point will depend on the distance of transmission, and must be determined by the following considerations: On the one hand, the prime cost of single-phase generators is higher than that of three-phase generators. On the other, there must be considered the cheaper switchboard, fewer insulators and 33 per cent. less labor required in erection of the overhead bare cable. As regards the running costs, it will hardly be disputed that the handling of the power station will be facilitated by a single-phase equipment; and with regard to outside maintenance, there would be only two lines to look after instead of three.

Testing Earth Connections.—H. Corsepius contributes to the *Elektrotechnische Zeitschrift* an article on earth connections. As is well known, the frames of electric ma-

chines are often grounded for safety's sake. The purpose of the earth connection is to make sure that any currents which may pass from the frame, etc., to earth will pass through the earth connection and not through a person who may be in contact with the frame. If such earth connections shall be effective, it is necessary to keep them in good order and to test them regularly. The author points out that tests made with small voltages, such as used with the testing bridge and the telephone, are not so reliable as tests made with higher voltages. In the case of an alternating-current installation, the author recommends to use the supply current itself for testing, of course, through the intermediary of the transformer, while for direct-current testing a small storage battery is used. Two different connections are shown for testing, one for direct-current testing and the other for both direct and alternating-current testing. By his method he has found the following values: An earth connection consisting of a large 1 by 1.5 meter sheet iron plate with a copper cable, screwed and soldered to it at various places, had a resistance of about 7 ohms. Wire used as earth connections, as is often done with lightning rods, had a resistance of about 50 ohms. Lead pipes, of 20 mm. external diameter, 10 meters long and embedded in a trench 1.2 meters deep, showed resistances of about 6.5 to 8.5 ohms, and are considered by the author as quite advantageous. Underground pipes which belong to a large network, such as water pipes and gas pipes, have a very low resistance.

Three-Phase Motors Operated from Single-Phase Mains.—J. Dalemont, in a recent number of the *Elektrotechnische Zeitschrift* shows how three-phase motors may be operated from single-phase mains with the aid of inductance and capacity. Fig. 7 shows the diagram of connections, in which *I, II, III* are the windings of an ordinary three-phase motor, *C* a condenser, *R* an inductance, and *A B*, single-phase mains. It will be noted that the phase, *I*, is connected in a reverse direction to the ordinary. The author gives the results of some experiments made with a one horse-power single-phase motor running at a speed of 1,500 r.p.m. The motor was first supplied from a three-phase circuit and tests were then made with the same motor on single-phase mains, the connections being as shown in Fig. 7 with the exception that phase *I*

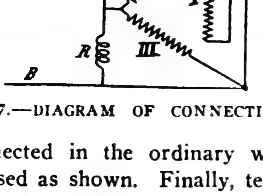

FIG. 7.—DIAGRAM OF CONNECTIONS.

was connected in the ordinary way, and not reversed as shown. Finally, tests were made with the motor connected as shown in Fig. 7, and the results of the tests are plotted in Fig. 8. The author points out that the motor may be thus operated successfully for continuous running. He also calls attention to the high value of the power-factor, and thinks that it would be

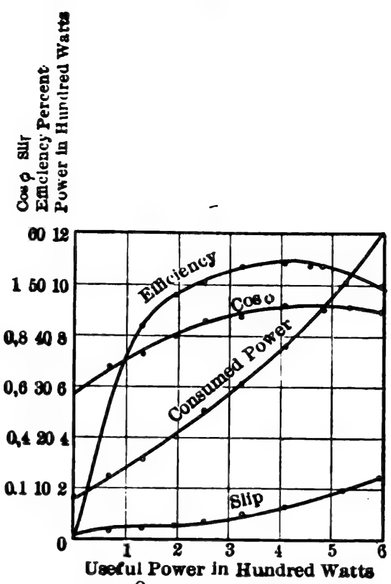

FIG. 8.—TEST CURVES.

possible to use three-phase motors in the manner described for traction purposes, only one overhead conductor being required.

Some Recent Electrical Patents

Switch for Heavy Currents.—A patent was issued recently to Mr. Frank Conrad and Mr. Arthur B. Reynolds, covering a

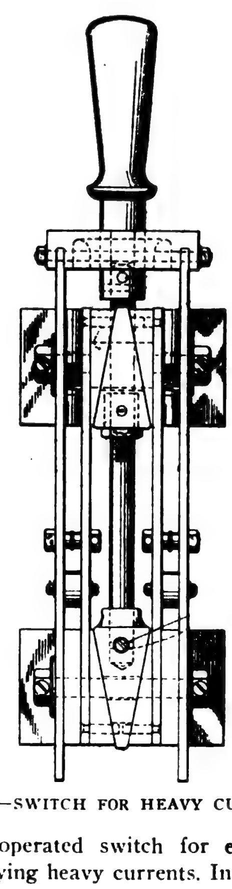

FIG. 1.—SWITCH FOR HEAVY CURRENTS.

manually-operated switch for electric circuits carrying heavy currents. In the single-pole switch shown in Fig. 1, at each terminal there are two stationary and four movable contact members. The handle which is provided for opening and closing the switch is rigidly attached to a rod upon which are properly mounted two wedges which move longitudinally when the handle is rotated. Each wedge is located between two blocks which serve to press against the switch blades when the wedge is moved in the proper direction. The wedges are provided in order that adjustment of the contact-terminals may be made after the switch is closed so as to increase the intimacy of contact between the movable and stationary contact members. By turning the handle, the parts may be loosened when it is desired to open the switch. Patent No. 803,212.

Rheostat.—The accompanying illustration shows a rheostat which formed the basis for a patent issued recently to Mr. George E. Stevens, of Lynn, Mass. The resistance unit consists of one or more

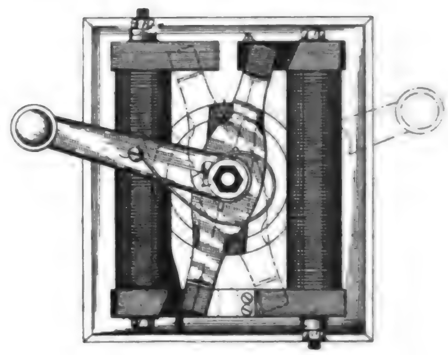

FIG. 2.—RHEOSTAT.

helical edgewise-wound resistance ribbons having their turns held in place by a cement which serves not only to insulate the turns but also to bind them together. The fixed element of the rheostat consists of two such units arranged parallel to each other and firmly secured to end blocks by means of bolts which extend through the interior of the units and through suitable apertures in the blocks. A rotary contact is mounted so as to rotate about a central post located midway between the resistance units and extending transversely thereto. As the operating handle is moved, the contact progressively engages the turns of the resistance winding. A spiral spring is provided for the purpose of returning the parts to the "off" position. A locking-magnet, the coil of which receives current through the field circuit, serves for holding the rotary contact in the position in which all of the resistance of the rheostat is short-circuited. Patent No. 803,452.

NOTES.

Electric Heating.—Mr. James I. Ayer has been appointed by President Blood, of the National Electric Light Association, to report on the Progress of Electric Heating at the next convention of the association.

Sale of Light and Power.—Mr. A. F. Sheldon, president of the Sheldon School of Scientific Salesmanship, delivered a lecture before the selling and canvassing force of the New York Edison Company on the sale of electric light and power. The lecture was well attended and illustrates the further adoption of progressive ideas by the New York Edison Company.

Rates and Costs.—The Committee on Rates and Costs, which made its report to the Denver Convention of the National Electric Light Association, has been reappointed by President Blood. The committee consists of Messrs. Charles L. Edgar, chairman; Louis A. Ferguson, Samuel Scovil, Frank W. Frueauff, P. G. Gossler and R. S. Hale. Mr. George W. Brine declined to serve again this year on account of ill health.

Lights on Transmission Towers.—The Niagara, Lockport & Ontario Power Company has decided to place electric lights on each of its transmission towers extending from the Devil's Hole near Niagara through Buffalo and Rochester to Syracuse. The plan is to surmount each tower with three lights, red, white and blue in color, which will be lighted during the summer months only, as the work of renewing the lights in cold weather would be too great.

Vermont Electrical Association.—The third annual convention of the Vermont Electrical Association was held at the Berwick House, Rutland, on October 25. The following officers were elected: President, E. E. Gaige, of St. Johnsbury; first vice-president, George E. Haley, of Rutland; second vice-president, E. E. Larrabee, of Bennington; secretary and treasurer, C. C. Wells, of Middlebury. Executive Committee—Frank Barney Jr., of Springfield; Frank Collins, of White River Junction; J. E. Davidson, of Montpelier; F. H. Parker, of Burlington, and E. D. Blackwell, of Brandon.

American Society of Mechanical Engineers.—The 52d meeting of the American Society of Mechanical Engineers will be held in New York City during the first week in December. The headquarters will be at the Edison Auditorium, 44 West 27th Street. The opening session, at which President John R. Freeman will deliver the annual address, will be held on Tuesday evening, December 5. The business session will be held next morning in the main saloon of the steamship *Amerika* at the docks of the Hamburg-American Line, Hoboken, N. J. Following this session, a special train will take those desiring to make the excursion to the Worthington works at Harrison, N. J. There will be an illustrated lecture by Professor R. W. Wood at the Edison Auditorium on Wednesday evening. The third session will be held on Thursday morning, and besides the presentation of professional papers there will be a discussion on the subject of "Bearings." In the afternoon there will be a reception at the New York School of Automobile Engineers, 146 West 56th Street. The usual reception at Sherry's will occur on Thursday evening. The closing session will be held on Friday morning and will be devoted to the presentation of professional papers.

CENTRAL STATION ENGINEERS.—XIV.

Walter L. Mulligan.

Walter L. Mulligan, manager of the United Electric Light Company, of Springfield, Mass., was born July 6, 1875, at Springfield, Mass. He acquired his early education in the public schools of his native city and afterwards entered Cornell University. He left the university at Ithaca in 1897 and entered the employ of the United Electric Light Company, of Springfield, as an electrician. Diligence and aptitude for business soon met with the approval of his superiors, for step by step he was promoted from one department to another, until in 1900 he was appointed assistant manager of the company. His broad knowledge in the field of electric lighting gained through service in almost

WALTER L. MULLIGAN.

every branch of the work, enabled him to perform the duties of this office with such efficiency that in 1902 he was offered the position of manager, which post he still holds.

New York Electrical Society Lectures.—Among the lectures scheduled by the New York Electrical Society for the season 1905-06 are the following: "Wireless Telegraphy," by William Marconi; "Electrification of the Long Island Railroad," by O. S. Lyford, Jr.; "Newspapers and the Telegraphic Art," by Melville E. Stone; "The Turbine," by C. G. Curtis; "The Place of the Electric Vehicle in Automobilism," by Robert McAllister Lloyd; "Single-Phase Railway Work," by C. F. Scott, and "The Block Signal System on the Subway," by J. M. Waldron.

Preserving Niagara Falls.—It is announced that Secretary Root will shortly open negotiations with the British Government for the purpose of reaching an agreement for the preservation of Niagara Falls from further utilization and to protect the scenic beauty of the spot.

The Chicago Electrical Trades Exposition.—Mention has already been made in these columns of the formation in Chicago of the Electrical Trades Exposition Company to hold an electrical show in that city the coming winter. The company has as officers and directors a number of prominent men in the electrical trade and central station work in Chicago. A circular has just been sent out announcing the plans in detail and giving plans of the exhibit space at the Coliseum, where the show is to be held. It will begin at 7 p. m. Monday, January 15, and continue until 10.30 p. m. Saturday, January 27, 1906. It will be open daily, except Sunday, from 10 a. m. until 10.30 p. m. Rental charges for exhibit space will be $1 per square foot on the main floor, and 50 cents per square foot in the balconies and galleries. Probably the conventions of at least three electrical organizations will be held during the time of the show, and exhibits made at this show will serve all the purposes of exhibits made at these conventions. Much interest is being displayed. The general manager is Thomas R. Mercein, secretary of the Northwestern Electrical Association, whose office is now 464 Monadnock Building, Chicago.

A Point for the Central Station Man.—Progressive central station men throughout the country are to-day greatly interested in methods of securing new business and large sums of money are expected each month with this object in view. The variety of ways in which the public can be interested in central station service is innumerable, but it is not always appreciated that many of the most effective texts for newspaper and other advertisements may be drawn from very ordinary sources. For example, it is widely the custom of dealers in bric-a-brac and crockery to use the incandescent lamp in displaying all kinds of ornamental lamp shades, rather than to light up the shades by gas or oil. Here is a plain confession on the part of the retail merchant that electricity is the cleanest, safest, most flexible and most artistic illuminating agent known to civilization, and the central station man who seizes upon such pointed and palpable illustrations of the superiority and attractiveness of his product may well turn his action to profitable advantage. There is a real bit of humor in selling gas or oil lamps through the agency of electricity—which lights such merchandise better than the illuminants for which the lamps were originally designed.

AMERICAN ELECTRICIAN

WITH WHICH IS INCORPORATED

Electrical Industries.

Issued on the first of each month by the

McGraw Publishing Company

114 Liberty Street, New York.

Philadelphia Office .... 929 Chestnut Street
Chicago Office .... Monadnock Building
Cleveland Office .... Cuyahoga Building
London Office, Hastings House, Norfolk St., Strand

Address all business communications to AMERICAN ELECTRICIAN, 114 Liberty Street, New York. Matter intended for publication in the reading columns should be addressed to the editor.

Subscription price, $1 per year, postage prepaid, in the United States, Canada, Mexico and Cuba; $2 in all foreign countries. The date on wrapper shows when subscription expires. Subscribers should give their old as well as their new address when requesting a change in address. This should be received a week in advance of the desired change. No copies are kept on sale beyond fifteen months from date of issue, except in bound volumes.

Advertising rates sent on application. Advertisements received for insertion up to the 25th of the month prior to date of publication. Changes in standing advertisements should be received not later than the 15th of the month to insure their insertion in the next issue.

Remittances should be by check, New York draft, express or postal money order, payable to AMERICAN ELECTRICIAN.

Entered in the Post Office at New York as second class mail matter.

Vol. XVII. DECEMBER, 1905 No. 12

THE AMERICAN ELECTRICIAN *has the largest circulation of any electrical journal published. Of this issue, 17,000 copies are printed. The total number of copies printed so far this year is 215,000, or an average of 17,917 per issue.*

CONTENTS.

To Our Readers:

With this issue the AMERICAN ELECTRICIAN ceases to exist as a separate publication, and beginning with the new year will be consolidated with the *Electrical World and Engineer,* the combined journals to be henceforth known as the ELECTRICAL WORLD. The *Electrical World and Engineer* dates from *The Operator,* founded in 1874. It became a weekly publication in the pioneer period of modern electrical development under the name to which it will shortly return; in 1899 consolidated with it the weekly *Electrical Engineer,* and during its long history has always and everywhere been recognized as the leading weekly electrical journal of the world.

The consolidation of the two journals does not, however, involve any sacrifice of the interests of the great body of readers whose encouragement and support have enabled the AMERICAN ELECTRICIAN to attain and hold the enviable position it has for the past ten years occupied in the field of electrical journalism. The monthly journal will, in fact, be continued as the first issue of the month of the ELECTRICAL WORLD, these twelve particular issues of a year being subject to a separate subscription of $1.00 per annum. All subscribers of this journal will receive this issue during the unexpired terms of their subscription. While retaining the features of the monthly to which it succeeds, this issue will also incorporate the practical features of the ELECTRICAL WORLD, the monthly reader thus being specifically served as in the past, but with an addition of reading matter that will greatly enhance to him the value of the journal without increasing its cost. The present editorial organization of the AMERICAN ELECTRICIAN will be continued and supplemented by the resources of the older weekly in gathering editorial material.

By this concentration of thought and effort heretofore spread over two great technical journals, it is believed that electrical readers of all classes will be served in a higher degree and more completely than has been possible in the past. As involving one of the most prosperous journalistic properties in this country, the step here announced was naturally decided upon only after the most careful thought on every consideration incidental to such a departure from the past methods of electrical journalism. That it will lead to a new record in this field of journalism the great resources of the combined publication assure; and that the loyalty to the AMERICAN ELECTRICIAN which has always so markedly characterized its readers and which in the past has been so great an inspiration in its conduct, may be transferred to its successor, is an ambition toward whose realization no effort will be spared, no stone left unturned.

Zinc in Storage Batteries.

In the early days of electrical science, before the invention of the dynamo, zinc was the electrical metal *par excellence.* Current was supplied by batteries which had a zinc plate as anode, whatever their construction in other respects. The advantage of zinc is to be found in its comparatively high energy of reaction, which results in a comparatively high voltage for zinc cells. In almost all cases in which zinc has been used in batteries it forms a soluble zinc salt which passes into the electrolyte during discharge. This means that the anode disintegrates and must be replaced by a new zinc plate, while there is considerable trouble in winning back the zinc from the solution. The chief disadvantage of zinc primary cells is the high price of zinc. In these cells zinc acts as the fuel, so to speak, and while the efficiency of the generation of electrical energy in the cell is high yet the fuel is very expensive.

The question naturally arises, why not try to use zinc in a secondary or storage battery? In this case after the cell has been discharged a current is sent through it in the opposite direction with the expectation that the chemical reactions during discharge would be exactly reversed. This is theoretically correct and in practice the reverse chemical reactions take place to a certain extent. However, there are two inherent disadvantages. There is, first, the difficulty of depositing the zinc back on the zinc plates in coherent dense form; secondly, the electrolyte will consist of a mixture of the zinc salt with free acid and when the charging begins the current has a tendency to decompose the acid instead of the zinc salt. While some zinc will be deposited, the main action will be the liberation of hydrogen; which means, of course, waste of current. It is for this reason that the lead-zinc storage battery, although it has given

comparatively good results in the laboratory, has proven a failure in practice.

The main advantage which the zinc-lead cell has over the ordinary lead cell is the higher voltage due to the higher energy of the reaction of zinc compared with the reaction of spongy lead. This higher voltage would undoubtedly be a great advantage, for instance, in automobile work. In this connection the new German zinc-lead cell described in this issue by Dr. Gradenwitz is interesting; but it is very doubtful whether under the severe conditions of automobile practice the cell will fulfill what its tests in the laboratory have promised. The inventor seems to suspect such troubles since he also provides for the use of the cell as a primary battery. If the zinc plates are thick enough, they will stand several discharges; and after one discharge it will be sufficient to replace the discharged lead peroxide plates by fresh ones and the solution by fresh acid. This is, of course, possible, but the cost of recharging the battery is not avoided. The only difference is that the lead peroxide plates are recharged and the solution is to be regenerated outside of the batteries. This simply adds the cost of handling the plates and acid to the cost of recharging. In practice two possibilities are open; either stations must be provided all over the country to perform the regeneration and always have fresh plates and fresh acid on hand, or the automobile has to carry these with it. In either case, it is difficult to see how the system can be a commercial success.

Broad Economy of Electric Heating.

Every central station manager who is alive to new business possibilities ought to understand thoroughly the broad economy of electric heating and press it home to the community which he serves. In many cases the idea prevails that electric heating is too expensive in comparison with coal and gas to warrant special efforts to sell power for that purpose. The station manager feels that he cannot show any financial saving to the consumer in large propositions and naturally turns his attention to the extension of the lighting and motor loads which offer more immediate and larger profits. These managers fail to realize that operating cost is but a single factor in the heating problem, and is not at all comparable to the immense advantage gained in educating any community to the point of appreciating the universal applicability of electricity to the affairs of civilized life.

The actual money paid for electric heating service is but a poor index of the value received. It is cheaper to walk five miles than to ride the same distance in a trolley car, so far as actual money expended is concerned, and a house may be lighted at less expense with candles and kerosene oil than it can be illuminated with gas or electricity. However, no person whose time is of any value whatever would think of making a five-mile journey afoot, and few householders to-day reject both gas and electricity for candles and oil if a central station circuit is available in the neighborhood. The same reasoning applies to electric heating. Its advantages are so much greater than those of other methods that unless the heating problem is a matter of large volume rather than a question of definite area, the broad economy of operation will lie with electricity. The required work can be done with absolute cleanliness; the power may be switched off the instant the heating process is over, and most important of all, the heat is concentrated exactly where it is needed. With gas or coal as fuel, about 80 per cent. of the energy is wasted, while with electricity about 80 per cent. or over is utilized.

These points are well known to electrical engineers and to consumers of electric heat, but they are still far from being appreciated by the general public. It, therefore, devolves upon the central station manager to keep the public constantly aware of the multiplying applications of electricity in heating service. The list of appliances now on the market covers an enormous range and almost any device specified can be promptly supplied; yet there are many towns where the central station manager has never exhibited an assortment of electric heating apparatus for the purpose of acquainting the public with what is being done in this interesting and essentially domestic field. A small heating load will not add much to the revenue of a central station, but if the thousands of consumers of electricity could be made to realize the exact field in which electric heating is supreme, central station managers would in the long run receive ample benefit.

The Steam Turbine and the Isolated Plant.

Recent developments in steam turbine design indicate that a wider field of usefulness has opened for these interesting prime movers. For some reason the adoption of turbines in isolated plant work has been rather slow in this country, but with the production of large direct-current units the outlook for more extended applications is much improved. Isolated plant practice covers a vast range of service, and the distances of transmission are almost always so short in comparison with those encountered in central station and traction work that direct current is probably used for the bulk of isolated plant loads at the present time. This preponderance of direct-current equipment naturally demands direct-current turbo-generators, and until quite recently the difficulties of commutation, balancing and armature construction for high peripheral speeds have proved serious obstacles in the way of direct-current turbine practice.

A large number of turbo-generators, made up of dynamos geared to their respective prime movers, is in use to-day, and although these machines have not been applied in very large capacities there seems to be no doubt that they are well adapted to the requirements of isolated plant service with either direct or alternating-current distribution. The production of gearless units broadens the field still more and paves the way toward the utilization of those special advantages which particularly recommend the steam turbine to installations where space is limited and loads extremely variable. The uniform angular velocity and freedom from vibration which characterize the steam turbine adapt it particularly to the use of hotel and apartment house plants, where noiseless operation is a desirable feature. The operating simplicity of the turbine is of special advantage in office building work, where a large part of the attendant's time is taken up in maintaining the heating system, piping and elevators in proper condition. With turbo-generators the necessity of stopping and starting various units to secure low steam consumption with load variations is of much less importance than in the case of the reciprocating engine. The foundations required in turbine practice are much less extensive than those needed in the same capacities of reciprocating engines, and the time required for installation is generally less as well. The regulation of small steam turbines is now well within two per cent from no load to full load, which means that the exacting conditions of office lighting can readily be met. The stimulus recently imparted by the manufacturers to the street railway power house market through the development of large direct-current units will doubtless lead to the extended use of turbine units in the isolated plant field, although the extinction of the reciprocating engine is not in the least probable.

DESIGN OF A BATTERY MOTOR.

BY CLARENCE W. COLEMAN.

The motor here described was designed by the writer for operating railroad semaphore signals, although its use is by no means restricted to this class of work. The armature of the motor is entirely enclosed in order to prevent dirt or frost from collecting on the commutator, since either of these would have a tendency to insulate the brushes from the commutator and militate against the reliable operation of the motor. Inasmuch as the motors are intended to operate from potash batteries, it is important that they be very efficient; but reliability of operation is of vastly more importance, and for this reason two sets of copper brushes are used. A brake is provided for the purpose of stopping the motor as soon as the power is cut off. The field magnets when energized attract the brake armature and lift the shoe from the brake wheel, and when they are de-energized a spring applies the brake shoe to the wheel. This is not necessary, but it is found desirable to prevent the mechanism drifting by its latch for the succeeding operation, which would necessitate the running of the motor for a longer period in order to bring the latch around again to operate the signal.

Fig. 1 is a side elevation of the complete motor, and Fig. 2 is an end elevation, looking at the commutator end. Fig. 4 is a cross-section between the pole pieces. Fig. 5 is a bottom view of one of the field magnets, and Fig. 6 is a side view of a field magnet ready for winding. The field magnets are built up of punchings, of which the yoke forms a part, and one-half the punchings in each field magnet has the yoke ¼ inch longer than the other half. The field magnets are built up with two long and two short parts alternately, as shown in Fig. 5, so that when they are put together they form a lap joint. When the proper number of punchings are assembled to make the desired width of field magnet, in this case 2¼ inches, they are clamped in a vice, and brass magnet heads, made in two pieces with a dove-tail tongue on one end and a corresponding groove on the other end, are put on so that the tongue in each end is pressed into the corresponding groove, as shown in Fig. 5; this holds the field magnets in shape for winding.

It is advisable to file the sharp corners of the punchings before putting on the insulation. Fibre heads should be placed next to the brass heads, and two layers of fibre 1/64 inch thick should be wrapped on the core.

The yoke should be clamped in a four-jaw chuck on a lathe and the winding put on. Both field coils should be made alike, and the inside ends of the windings should be soldered together. Each one of the coils should have 220 turns of No. 11 magnet wire. After the field magnets are wound they are put together with a strap on each side, as shown in section by Fig. 4, with a screw through each side of the center, and are then clamped. The field clamps, Figs. 7 and 11, should now be attached, the punchings being held against the extensions of the clamps which fill the space between the poles, and the screws drawn up to hold the parts in place. The field magnets should then be put in the cast-iron base and the wedges driven in so as to hold the magnets in place and force the ends of the punchings together.

The field clamps have the surfaces which bear against the field magnets and the edges of the extensions which go between th poles, finished true, and the inside is bored out true also. The ends of the extensions are finished so one fits into the other about ¼ inch, as shown in Fig. 4. This makes practically one piece of the two clamps and holds them in line with each other, prevent-

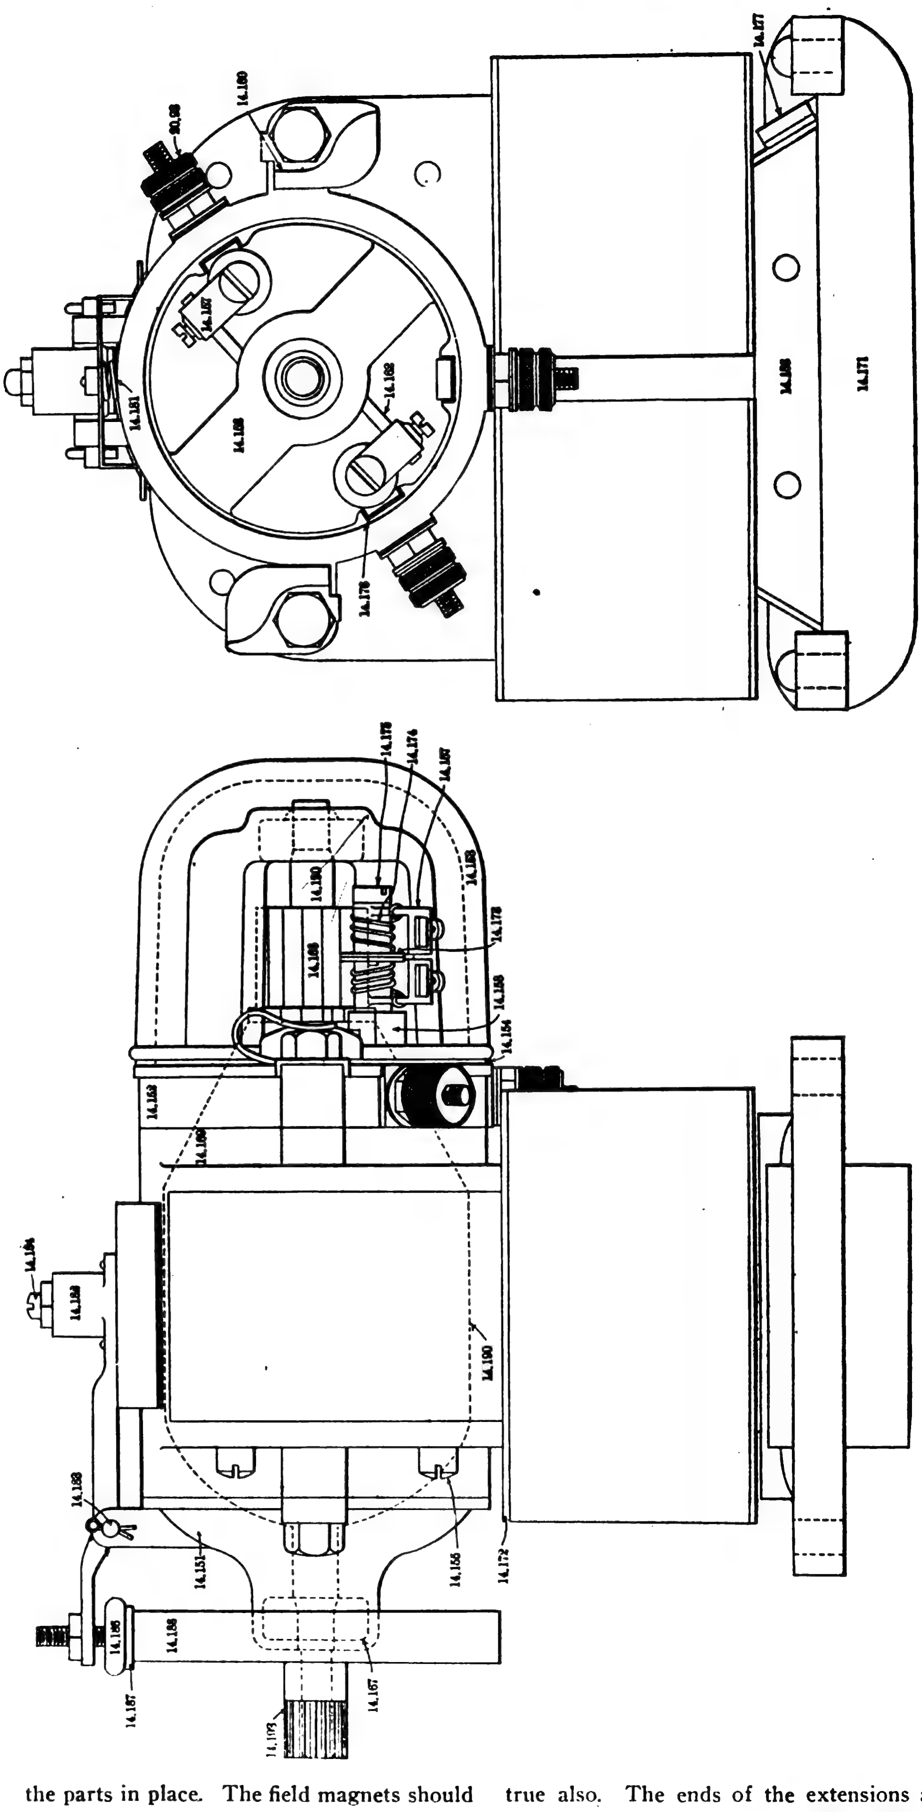

FIG. 1.—FRONT AND SIDE ELEVATIONS OF BATTERY MOTOR.—FIG. 2.

ing the punchings standing on an angle when clamped between them. The extensions on the field clamps fill the space between the pole pieces in order to enclose the armature, and they also form an abutment for the pole pieces so that these cannot be forced against the armature. The field clamps are finished on the outside where the bearing supports come against them. The field magnet laminations are the most difficult parts to make unless one has a punch and die, and the writer has found it cheaper to make a punch and die for this purpose than to machine them. A cheap die can be cut in ¼-in. sheet tool steel, and fastened on a heavy cast-iron base with an opening to let the punchings through. The punch can be made of the same material, mounted on a cast-iron head. It is not necessary to harden these to punch enough pieces for one or two motors, if thin material is used.

The punch and die should be made for the long yoke piece and ¼ inch cut off half of the punchings for the short yoke piece. With the one joint between the fields lapped, and the ends butted together, besides being wedged in a cast-iron base, the magnetic loss on account of joints is reduced to a minimum. Fig. 3 shows a cross-section of the armature and commutator mounted on the shaft. The armature discs shown in Fig. 8 are made of refined sheet iron .015 inch thick and dipped in shellac which is allowed to drain off. For convenience in assembling the armature core discs a brass tube, shown in section on the shaft, is placed on a heavy metal disc having openings to correspond to those in the armature discs, and a bolt passed through both. A fibre disc is now put on, followed by enough armature discs to give the required core length (in this motor, 2¼ inches) when drawn tightly together; then a fibre disc and finally a heavy metal disc are put on. The nut is placed on the bolt and screwed up tight, thus drawing the discs together. The fibre insulations are put in the arma-

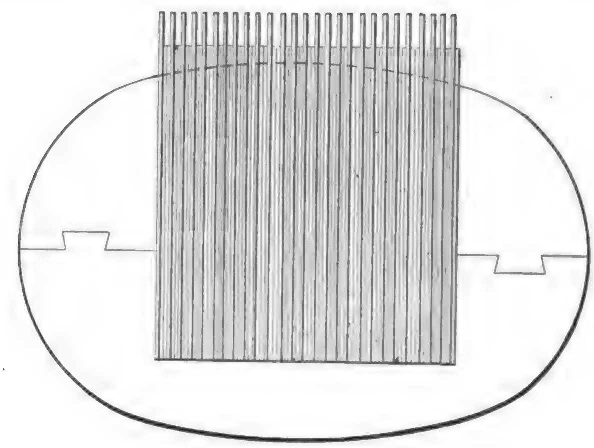

FIG. 5.—BOTTOM VIEW OF FIELD MAGNETS.

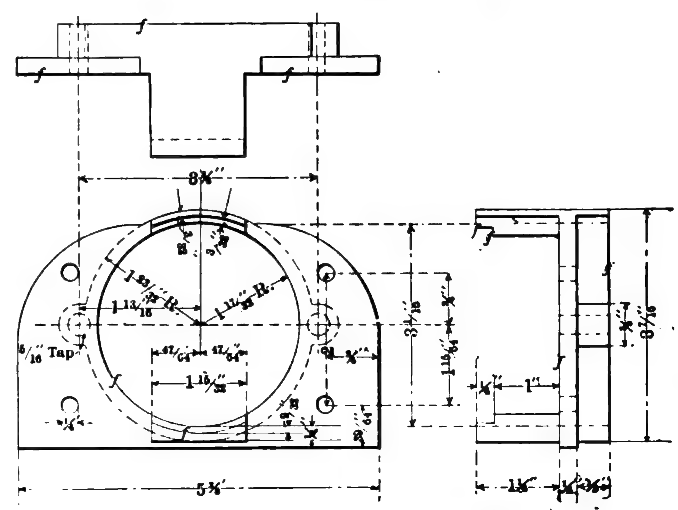

FIG. 7.—FIELD CLAMP, PINION END.

ture slots, extending to a little beyond the ends of the armature, and a plug is put in each slot to hold the fibre in place. The

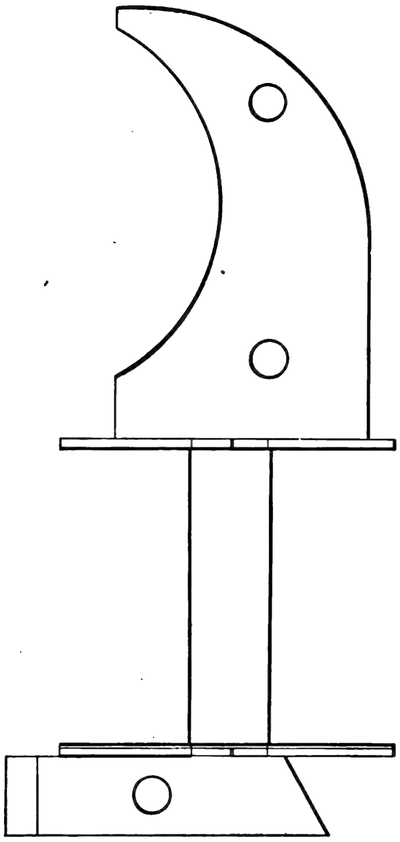

FIG. 6.—FIELD MAGNET PUNCHING.

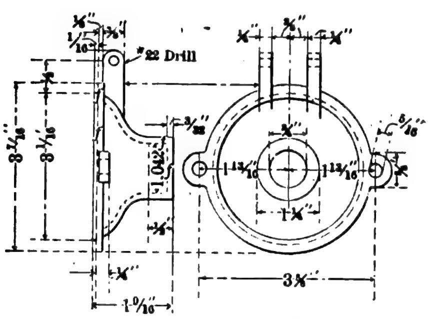

FIG. 10.—BEARING SUPPORT.

and a ⅛-in. hole drilled in each end, deep enough to cut through the tube on each side, and into the discs and shaft, thus forming a keyway. A pin is driven in each hole, which should be drilled ¼ or ⅜ ins. deep.

The shaft on each side of the armature should be covered with some insulator to prevent the wires from grounding on it; this insulation should extend a little beyond where the wires will come. A thin fibre tube or a thin fibre sheet wrapped around the shaft and held in place will suffice. The armature is now ready for the armature

wind slots 10 and 18; then choose a pair of slots as far removed as possible, say 4 and 14 and 5 and 13; after winding each coil

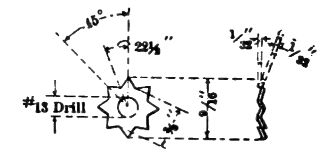

FIG. 15.—SPRING ADJUSTER.

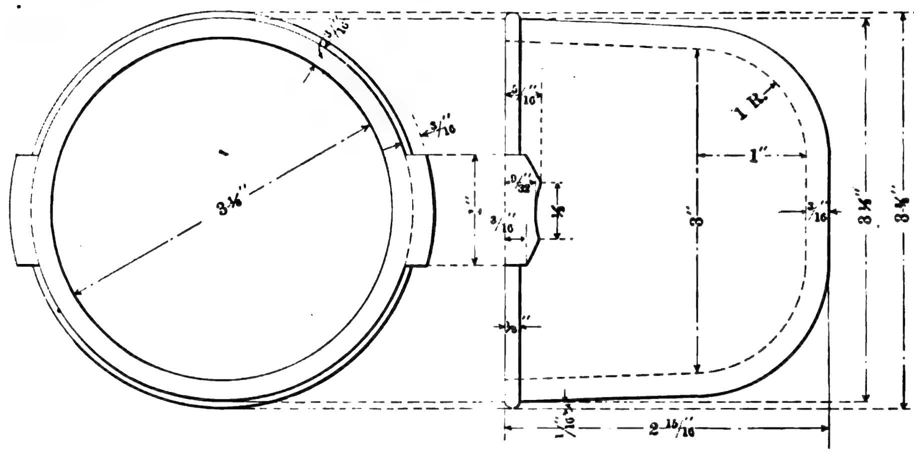
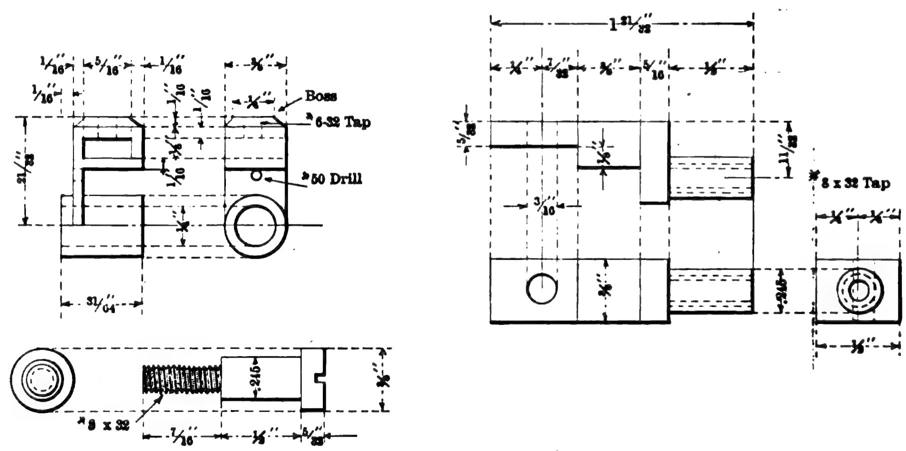
give the armature one-half turn. This will leave two slots directly opposite each other to be wound. The outside coils are wound



GLASS COMMUTATOR COVER.



FIGS. 12, 13 AND 14.—BRUSH-HOLDER, SUPPORT AND SUPPORT SCREW.

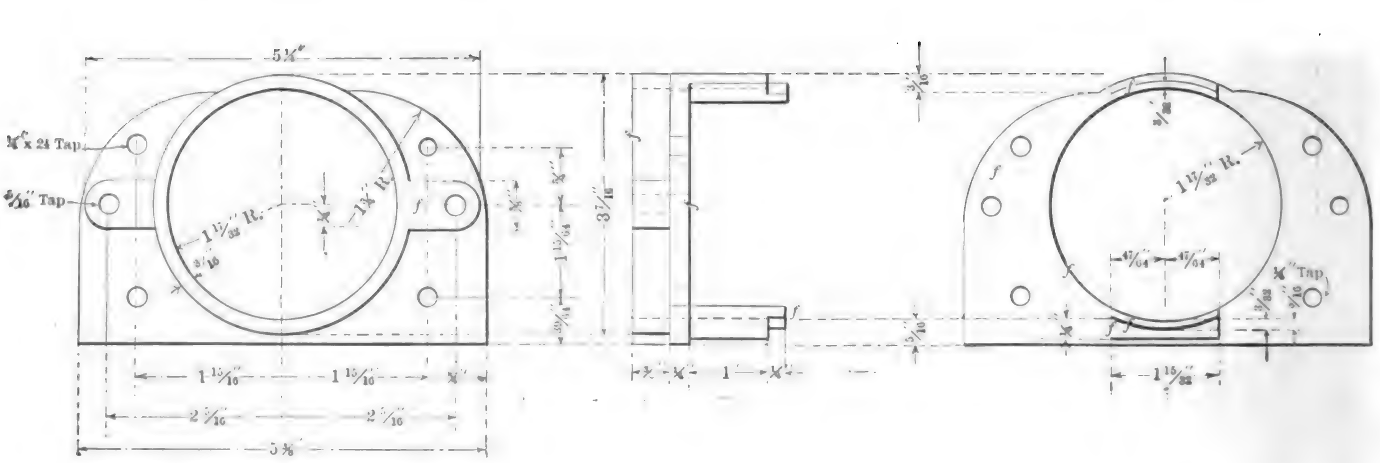


FIG. 11.—FIELD CLAMP, COMMUTATOR END.

armature is then baked and allowed to cool. When cold, the plugs are pulled out of the slots, the bolt removed, and the heavy metal discs taken off. The armature core will then appear as one solid piece of metal.

The armature is now forced on the shaft

wires. The writer prefers the spiral winding, but for one not having much experience the skip winding is simpler. Commencing with the wire toward the commutator, wind slots 1 and 9 (see Fig. 8); then give the armature one-half a turn and

the same as the first, starting the wire in the slot diametrically opposite the one in which the coil already in these slots was started. The starting wire of each coil should have a knot or other means of identification in it to identify it when connect-

ing it to the commutator. It is necessary to use care in winding the armature to protect the insulation on the wire from injury, so that a coil may not be short-circuited on itself or grounded on any part of the armature or shaft. This motor was designed for thirteen turns of No. 18 double cotton-covered magnet wire in each coil, or twenty-six wires in each slot. It is advisable to put a piece of linen over each pair of coils on the end of the armature so when the next pair is wound across them there will be no danger of the wires cutting through the insulation, and each coil should be shellaced and the armature baked after the winding is finished. The commutator is next put on the shaft and secured with a set screw or pin, care being exercised to put the screw or pin as near the end as possible, so that there will be no danger of grounding the bars.

The terminals of the armature windings can now be soldered to the commutator, a flux being used that will not corrode the wire; rosin is safest. The inside or starting end of one coil should be soldered to one bar with the outside end of the coil next to it, all the coils being connected in this way. This operation completes the armature.

The commutator is a difficult part to make unless one has special machinery; but a suitable one can be made from either a

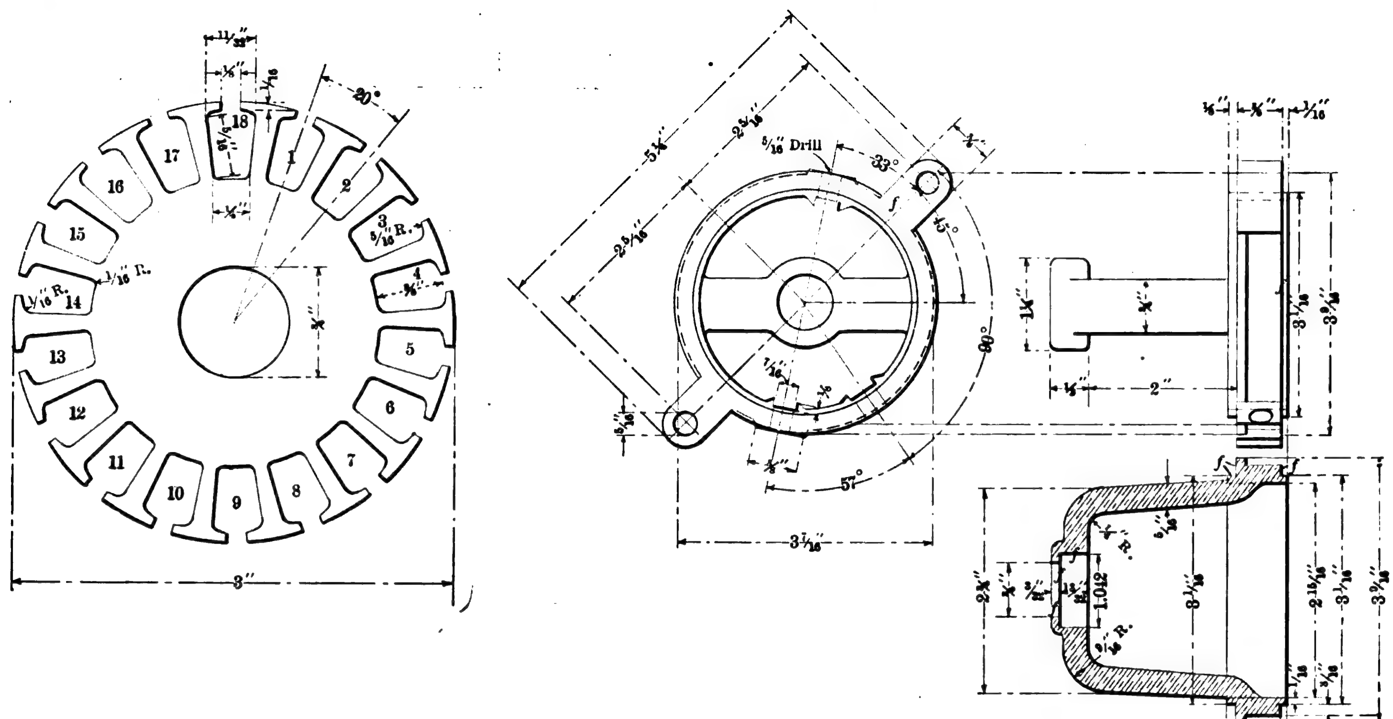

FIG. 8.—ARMATURE PUNCHING AND BRASS YOKE.—FIG. 9.

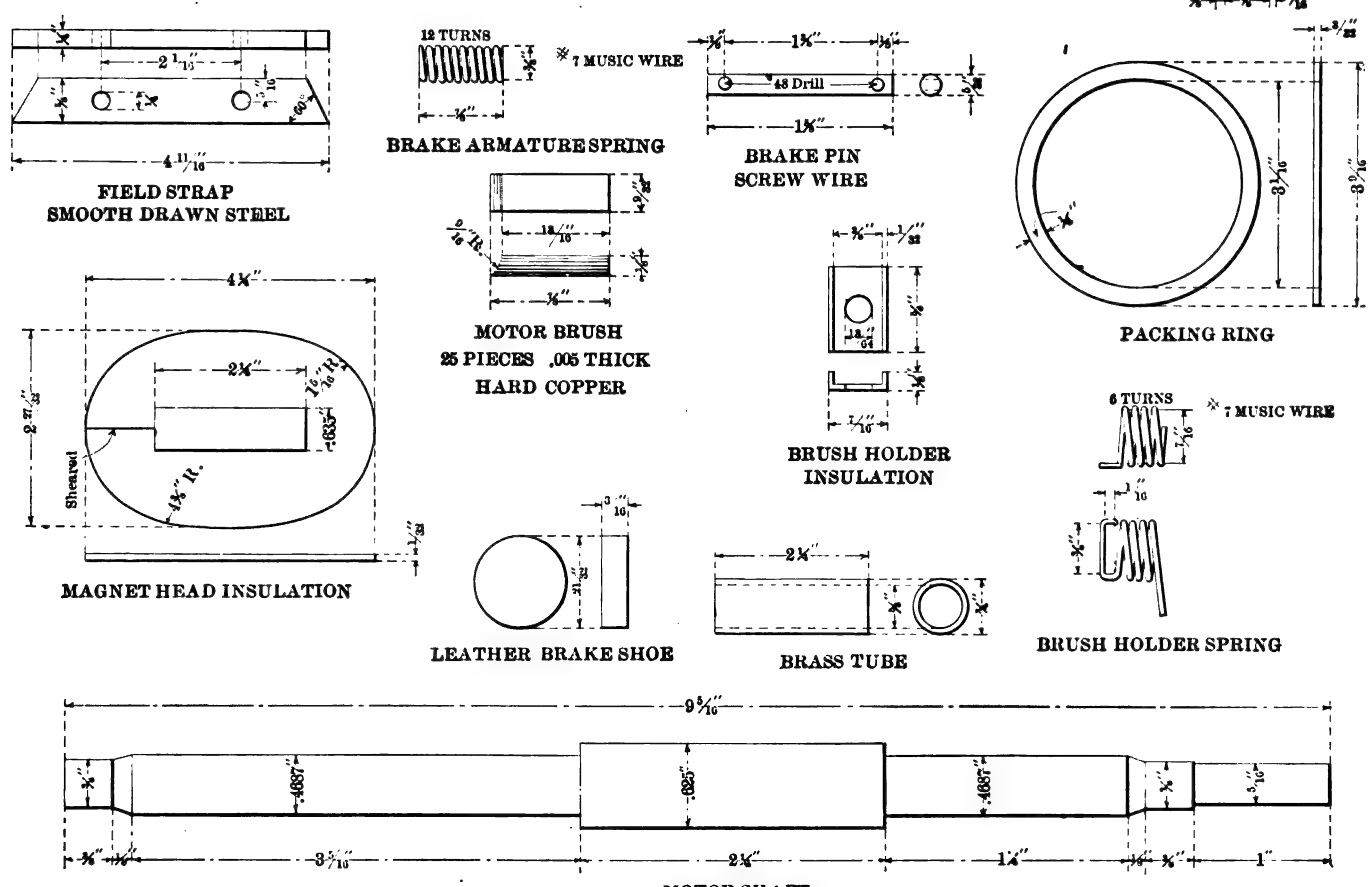

FIG. 16.—DETAILS OF MOTOR.

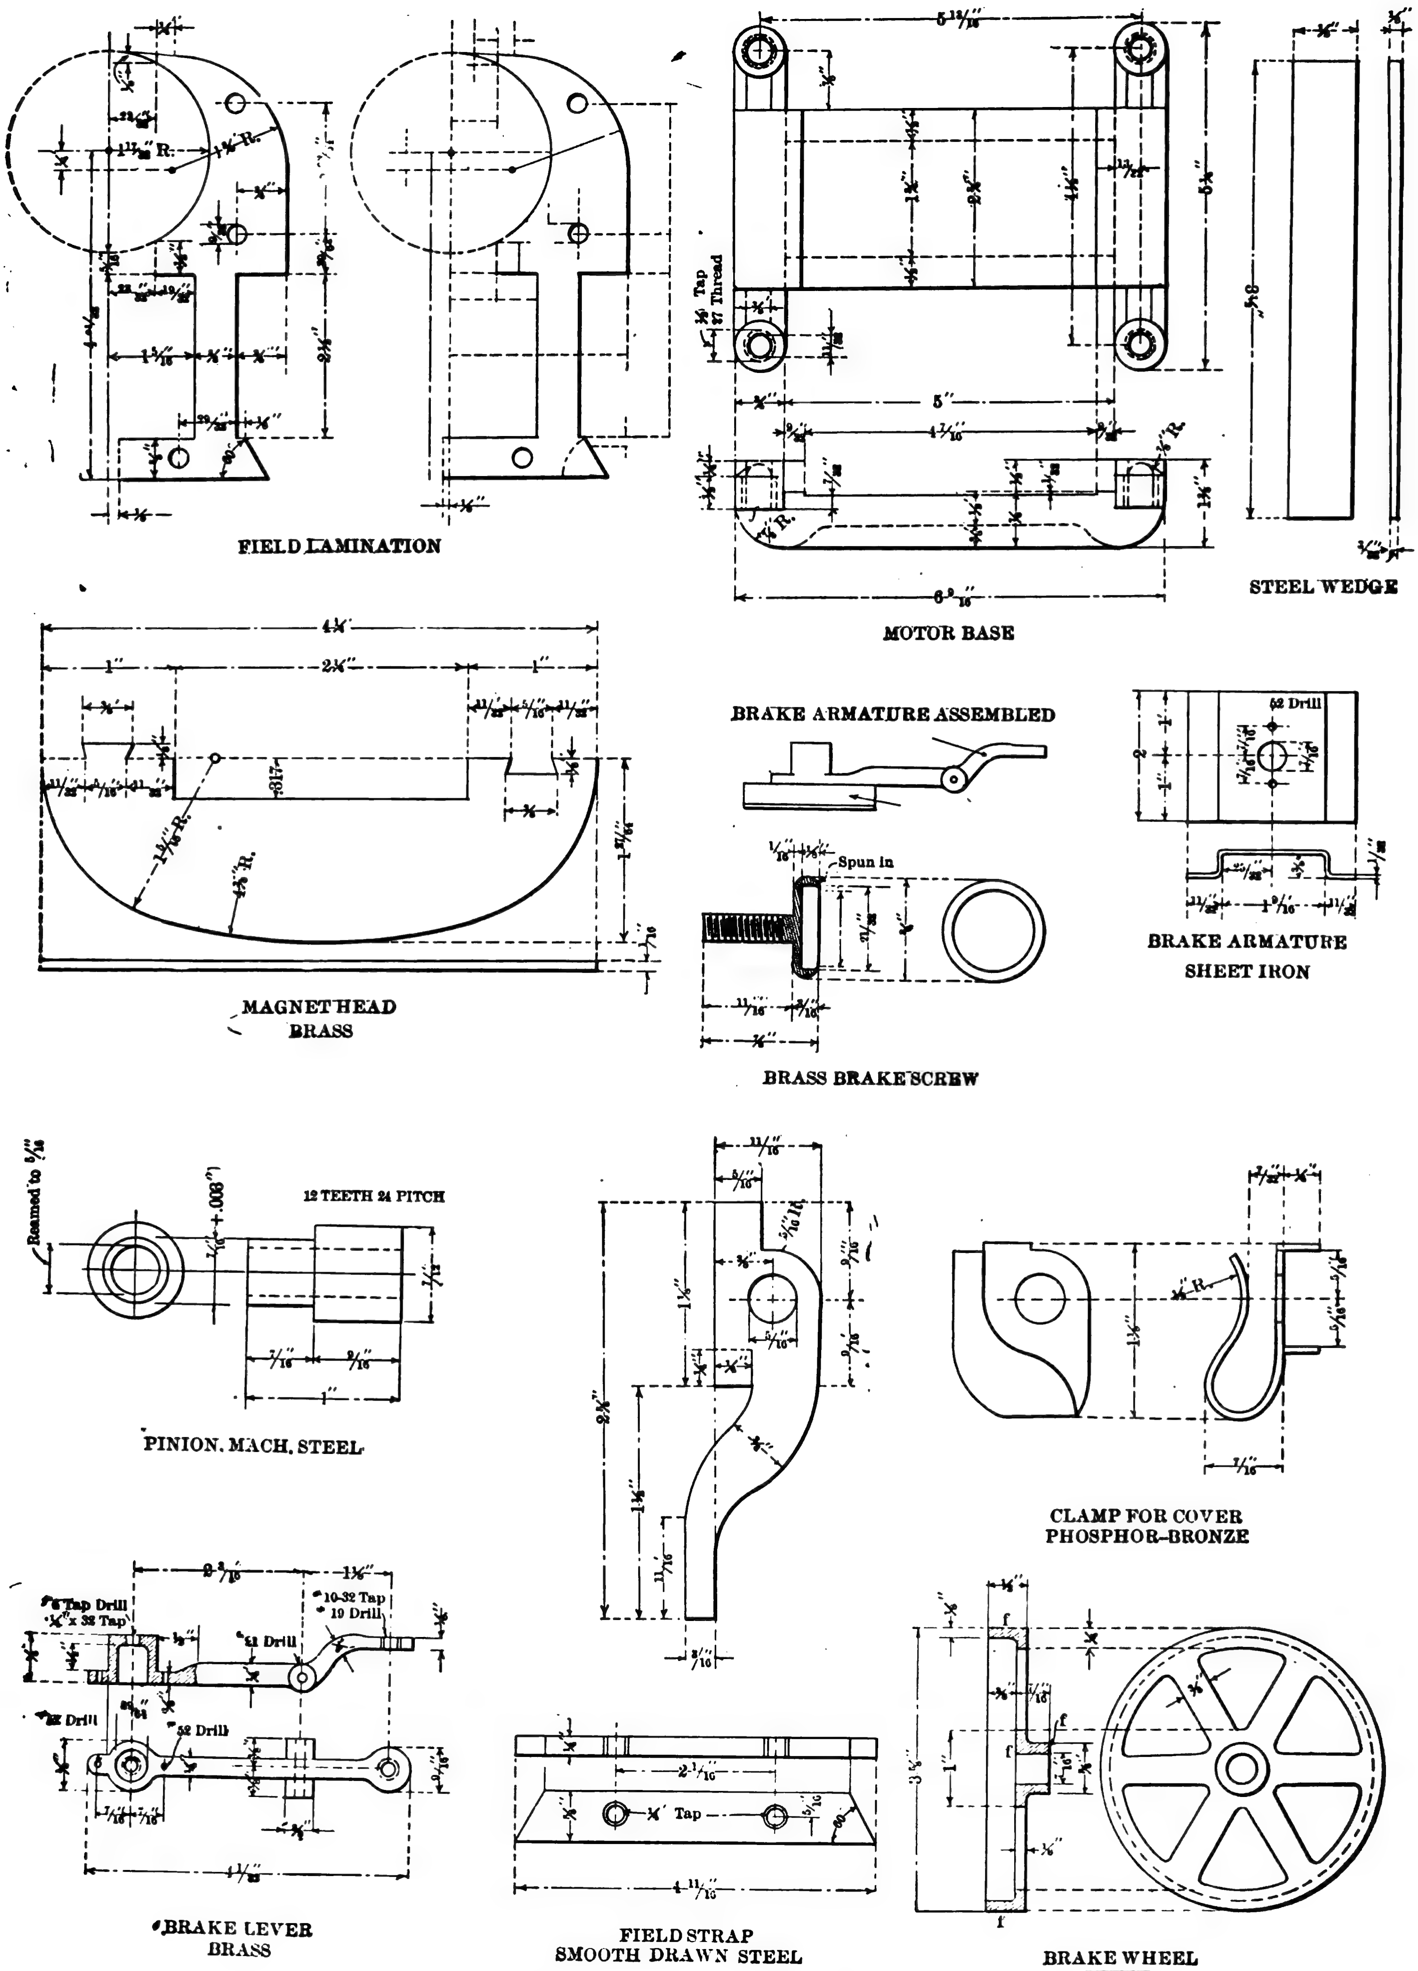

FIG. 17.—DETAILS OF MOTOR PARTS.

piece of copper as large in diameter as the commutator is to be, a piece of rod or very heavy tube, and boring the inside to the right size to fit the sleeve with the insulation on. This should be soldered on an arbor which has been turned on centers to fit it. The arbor is placed on centers, the ends of the copper turned to the proper taper, and the outside nearly to size; it can then be put in a milling machine and the tube cut in the proper number of sections, using a thin cutter. After this, enough heat to melt the solder is applied, and the segments will drop off the arbor. The commutator segments can now be assembled on the sleeve with mica and shellac, the nut screwed up tightly, and the whole baked. After it has baked a couple of hours the nut should be tightened up as much as possible while the complete commutator is hot. When the commutator is cold, it should be mounted on the armature shaft and a finishing cut taken over the face; this will insure the commutator running true on the shaft.

The armature is designed to run on ball bearings, one of which is shown in section on the end of the shaft. Bearings of this type can be bought already made. The bearing support for the pinion end, Fig. 10, encloses the armature on the end; it is finished with a shoulder which fits inside the field clamp, Fig. 7, so that it will always take its proper place when put on. The yoke, Fig. 9, is finished so that the shoulder fits in the field clamp, Fig. 11. Channels are cut in the inner surface of the ring for holding the brush-holder supports in their proper positions. The outer edge of the ring of the yoke is made a finished fit for the glass bell and a soft leather washer is put between the glass and the metal to make a tight joint. The glass bell is held against the leather by two springs bearing against lugs on the glass; this completely encloses the armature and commutator, and enables the attendant to see the condition of the commutator and brushes. The glass cover may be removed by turning it partly around; this moves the lugs from under the springs. To replace it, the cover is held against the leather and turned slightly to bring the lugs under the springs.

The brush-holder supports, Fig. 13, are secured in two channels cut in the ring of the yoke, by a square head screw passing through the support and the ring, with nuts on the outside, which serve as binding posts.

This being a series motor, one end of the field winding is connected to one of these posts, and the other is connected to the battery wire. The third channel in the ring serves to hold a square head screw to be used as a binding post to connect the other end of the field and the other battery wire. The brush-holder supports and the screws are insulated from the ring by a flat piece of insulation bent around the support and bushings through the ring.

One brush-holder, Fig. 12, is placed on the support, and another on the screw fastened in the end of the support. Each brush-holder has a separate spring. Two washers, Fig. 15, are placed on the screw, Fig. 14, which jams them against the end of the support, Fig. 13. The end of each brush-holder spring is fastened to its respective washer.

To adjust the tension on the brushes the screw, Fig. 14, is loosened and the washers, Fig. 15, turned until the proper tension on each brush is obtained; the screw is then tightened and holds the washers in the proper positions.

The motor runs at a speed of 2,256 r.p.m. when supplied with current at a potential of 11 volts, using ½ ampere. On a brake test the motor made 1,240 r.p.m., exerting a pull of 10 ounces at a 2-in. radius, consuming 2.2 amperes at 11.5 volts. For ordinary use many changes might be made in the design. The glass covering for the commutator with its parts might be omitted, as well as the entire braking mechanism for stopping the motor when the power is off. Other minor modifications might possibly present themselves.

TABLE I.—MOTOR DETAILS.

Part No.	No. Req.	Name of Part.

BOILER POWER FOR LIGHTING AND POWER PLANTS.

BY CHAS. L. HUBBARD.

It is often necessary to estimate quickly the boiler power required for heating, lighting or power purposes, and at such times a simple method giving results of sufficient accuracy for all practical purposes may be of considerable value. The following data have been used by the writer with satisfactory results and may be easily condensed and placed in a note book for easy reference. Computations for power boilers are based on the steam consumption of the type of engine used, and vary even with the same type of engine, depending upon the size, speed, pressure carried, and point of cut-off. The accompanying table (1) gives about the average steam consumption per indicated horse-power per hour for first-class engines of medium size.

TABLE I.

Type of engine.	Pounds of steam indicated horse-power per hour. Non-conds'g.	Conds'g.
Simple high speed	30—34	22—26
Simple Corliss	26—30	20—24
Compound high speed.....	24—28	18—22
Compound Corliss	22—26	16—20
Triple exp. high speed....	22—26	16—20
Triple exp. Corliss........	20—24	14—18

The higher figures may be used for engines of 75 to 200 horse-power and the lower figures for engines of 200 to 500 horse-power. For engines smaller than 75 horse-power, the figures should be slightly increased.

Having determined the probable weight of steam required per hour, and knowing the temperature of the feed-water and the boiler steam pressure to be carried, the weight of steam required can be reduced to an equivalent evaporation from and at 212 degrees, and this result divided by 34.5 will give the boiler horse-power required.

Before taking up a practical example, it may be well to state briefly just what is meant by "equivalent evaporation." It is known that the latent heat of evaporation varies with the pressure, and that the "heat in the liquid" varies both with the pressure and with the temperature of the feed-water. These facts show that in making comparisons of the efficiency of boilers working under different conditions, the working conditions of each must first be reduced to a common standard. This standard is called the "equivalent evaporation from and at 212 degrees," and is best explained by the following example:

A boiler carrying a pressure of 90 pounds gauge, and supplied with feed-water at a temperature of 60 degrees, evaporates 3,000 pounds of water per hour. What is its equivalent evaporation from and at 212 degrees? Reference to steam tables will show the temperature of steam at 90 pounds pressure to be 331 degrees, and the "latent heat of exaporation" 881 heat units; then for one pound of steam the "heat in the liquid" above the temperature of the feed-water is $331 - 60 = 271$ heat units, and the "total heat" is $271 + 881 = 1152$ heat units. Therefore, the heat required to raise the temperature of 3000 pounds of water from 60 degrees and evaporate it into steam at 90 pounds pressure is $115 \times 3000 = 3{,}456{,}000$ heat units.

Referring again to a steam table, one finds the "latent heat of evaporation" for steam at 0 or atmospheric pressure to be 966 heat units; therefore, $3{,}456{,}000 \div 966 = 3577$ pounds, which is the weight of water that would be evaporated from a temperature of 212 degrees into steam at atmospheric pressure by the same amount of heat. The ratio,

$3577 \div 3000 = 1.19$, is called the "factor of evaporation."

Tables giving the factors of evaporation for all conditions of feed-water temperature and steam pressure can be found in any engineers' handbook. To use such a table, look in the first column for the temperature of the feed-water supplied; then follow to the right until the column corresponding most nearly to the given boiler pressure is reached. The number here found will be the factor of evaporation for the case in hand, and the actual quantity of water evaporated multiplied by the factor thus found will give the equivalent evaporation from and at 212 degrees.

For example: What is the horse-power of boiler required to supply steam at 100 pounds gauge pressure from feed-water at 60 degrees temperature for a compound condensing Corliss engine of 200 indicated horse-power? Taking the higher water rate from Table I for this type of engine, we have $200 \times 20 = 4000$ pounds of steam required per hour. Reference to a table of the factors of evaporation shows the factor for the condition given to be 1.19. Therefore, $4000 \times 1.19 = 4760$, which is the equivalent evaporation from and at 212 degrees, and $4760 \div 34.5 = 138$, the boiler horse-power required.

If steam is to be used for other purposes, such as the running of feed pumps, etc., the power must be increased accordingly. It is also well to allow a margin for a future increase in the power of the engine, should occasion require it. In computing the power of a boiler in this manner, it is wise to increase the result obtained from 10 to 20 per cent for the reasons given above.

The boiler power required for running a pump is computed in a similar manner to that already described for an engine. The rating or capacity of a pump, however, is usually expressed in gallons of water per minute raised to a given height, instead of in horse-power as in the case of an engine. The weight of water in pounds per minute, multiplied by the height in feet to which it is raised and divided by 33,000 will give the useful or delivered work of the pump in horse-power. The friction of the moving parts of a pump and of the water through the passages and valves is so great that under ordinary working conditions not much more than 50 per cent of the indicated horse-power of the steam cylinder is utilized in doing useful work. This calls for a large consumption of steam in proportion to the work done, and from 80 to 120 pounds of steam per delivered horse-power is common in this class of pumps. The higher figure should be used for small boiler feed-pumps, while 100 pounds may be taken as a fair average for pumps of moderate size. In measuring the head against which a pump is working, the vertical distance between the surface of the water in the suction reservoir and that in the discharge reservoir is taken. If the pump is delivering against a pressure, as in feeding a boiler, the pressure should be reduced to "feed head" by dividing the pressure in pounds per square inch by .4.

For instance, if a pump is discharging 4000 pounds of water per minute into a tank 50 feet above it, and the surface of the water in the reservoir from which it is taken is 10 feet below the pump, $50 + 10 = 60$ feet, the total head against which the pump is working, and $4000 \times 60 \div 33{,}000 = 7.2$ horse-power.

Again, if a boiler feed-pump is delivering 200 pounds of water per minute against a pressure of 150 pounds per square inch, the water being taken from a reservoir 5 feet below the pump, the boiler horse-power may be ascertained as follows, assuming the pump to use 120 pounds of steam per delivered horse-power-hour, $150 \div .4 = 375$ feet head, $375 + 5 = 380$ feet total head, and $200 \times 380 \div 33{,}000 = 2.3$ delivered horse-power, from which the steam required will be $2.3 \times 120 = 276$ pounds per hour. If the temperature of the feed-water is 60 degrees and the boiler pressure 150 pounds, the factor of evaporation will be 1.2, and $276 \times 1.2 = 331$ pounds, the equivalent evaporation from and at 212 degrees. Therefore, $331 \div 34.5 = 9.6$, the boiler horse-power required.

In the above example it has been assumed that the horizontal runs in the suction and discharge pipes are short, and no account has been taken of friction.

The power required for electric lighting can be determined very nearly by assuming that one horse-power of electrical energy will supply a given number of lamps of different types, as indicated in the following table:

TABLE II.

No of lamps supplied by 1 h.p.	Type and power of lamp.
12	16-c.p. incandescent lamps..
6	32-c.p. incandescent lamps.
2.5	1200-c.p. arc lamps.
1.7	2000-c.p. arc lamps.

The efficiency of a first-class generating set (engine and dynamo) including the losses in transmission may be estimated at about 75 per cent, so that the electric horse-power necessary to supply the lamps divided by .75 will give the indicated horse-power of the engine required. From this the boiler horse-power can be determined as already described.

For example, it is desired to find what boiler horse-power will be required to furnish steam for a lighting plant carrying 2400 16-c.p. and 600 32-c.p. incandescent lamps and 100 1200-c.p. arc lamps; the boiler pressure to be 100 pounds and the feed-water delivered at an average temperature of 70 degrees. The engines are to be high-speed compound non-condensing, using 28 pounds of steam per indicated horse-power. Dividing 2400 by 12, the number of 16-c.p. lamps supplied by one horse-power according to the table, equals 200; $600 \div 6 = 100$, and $100 \div 2.5 = 40$, making a total of 340 horse-power of electrical energy required of the dynamos; $340 \div .75 = 453$ indicated horse-power of the engines; $453 \times 28 = 12{,}684$ pounds of steam required per hour. Since the factor of evaporation for 100 pounds steam pressure and 70 degrees temperature of feed-water is 1.15, $12{,}684 \times 1.15 = 14{,}586$ pounds, the equivalent evaporation from and at 212 degrees, and $14{,}586 \div 34.5. = 422$, which is the boiler horse-power required.

When a building contains a power plant the exhaust steam is usually turned into the heating system. In this case, the boiler power for supplying the engines and pumps is first computed, and about 80 per cent of the steam furnished for this purpose may be considered available in the exhaust for heating purposes. If this is less than is required for heating in the coldest weather, additional boiler power must be provided to make up the deficiency.

In designing a plant of any considerable size, it is better to use two or three smaller boilers rather than a single large one, and it is also well to provide for a certain amount of reserve power for use in case of break-down, or when it is desired to shut down a boiler for cleaning or inspection. In a heating plant, if sufficient power is provided for the coldest weather, there will be much of the time when only part of the boilers will be in use; but in the case of a power plant where the demand for steam is practically constant one or more extra boilers, depending upon the size of the plant, should be kept in reserve.

GROUND DETECTORS AND THEIR CONNECTIONS.

BY JAMES T. COE.

When the current in a wire escapes by any means to the ground, the wire is said to be grounded. This grounding may or may not entail serious trouble, depending on whether the circuit is purposely grounded or not. In electric railway systems, for instance, where the track circuit is grounded, no damage results unless a second ground of low resistance occurs between the trolley circuit and the earth. This would be the same as a direct short-circuit, and were it not for the fact that the generators and instruments are protected by fuses and circuit-breakers which instantly interrupt the circuit under such conditions, much damage would result. In the Edison three-wire system in which the neutral wire is grounded, an accidental connection between either of the outer wires and a gas or water pipe would cause current to flow which may be serious in its effects. In a circuit otherwise free from grounds, as for example a two-wire circuit, an accidental ground between one wire and the earth would not be fraught with serious consequences; but should a second ground occur between the other wire and the earth, current will flow through the connection thus established, the extent of the resulting damage, if any, depending on the e.m.f. of the circuit and the resistance of the grounded connections. The secondaries of transformers and many arc light systems are grounded, the better to protect the lives of people in case of mishap. Transformer cases are also grounded so as to protect users from shock due to primary leakage and accidental contact with the transformer case.

The causes of grounds are many and varied. It must be borne in mind that current always has a tendency to escape and

hence the need of insulation to prevent it. Where this is broken trouble may be looked for. In long transmission lines a broken insulator would allow the bare wire to touch the pole and thus establish a connection through the pole to ground. Trees falling across wires, branches swayed by the wind striking them, or grounded wires such as telegraph or telephone wires coming in

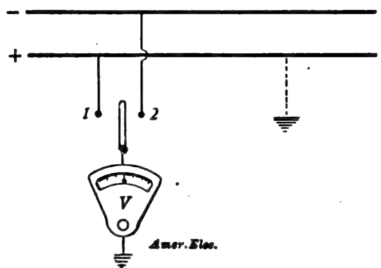

FIG. 1.

contact with electric light wires, cause grounding. In interior work a wire may come in contact with gas, steam or water pipes, or with iron girders, etc.; but the widespread use of conduit precludes such possibilities. When the contact is not good, or where the resistance of the conducting material is high, only a very small current will pass; on the other hand, if such is not the case and the resistance of the grounded connection is low, enough current will flow to temporarily, at least, disable the system.

The purpose of a ground detector is to indicate the presence of such grounds which are not readily discernible, and which if permitted to exist might cause serious trouble. A heavy ground needs no detector since it does not stand on ceremony in announcing its presence, and usually makes itself known by the blowing of fuses and the opening of circuit-breakers. Where these protective devices are not installed the apparatus usually receives its quietus, accompanied by weird noises and fireworks. Ground detectors may be connected directly to the circuit so as to indicate grounds just as soon as they occur, or they may be normally disconnected from the lines and thrown into circuit when it is desired to

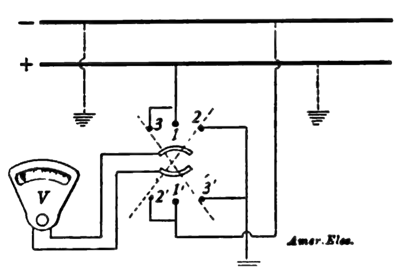

FIG. 2.

test the lines for grounds. It is the purpose of the writer to describe the various types of ground detectors in use and to show how these are connected to the circuits.

A voltmeter makes a very convenient ground detector since it indicates the presence of a ground as well as its comparative resistance. This instrument may be connected to direct-current mains as indicated in Fig. 1. The positive and negative mains are connected to contacts 1 and 2, respectively, of the switch *S*, which is connected to ground through the voltmeter. The voltmeter is double deflecting so that the needle swings in either direction, depending on the direction of the current. If the positive line should become grounded as indicated, and the switch placed on contact 1, no deflection will take place, since both the ground and the instrument are on the same side of the circuit. If the switch is thrown on contact 2 current will pass from the positive main to the ground and back through the voltmeter to the negative main, thus completing the circuit. When a deflection is obtained on the voltmeter with the switch on contact 1 it indicates that the negative lead is grounded, and conversely if a deflection is obtained with the switch on contact 2 it indicates that the positive main is grounded. Should the resistance of the ground be great the voltmeter deflection will be small, and if the resistance be small the voltmeter deflection will be large.

Many direct-current voltmeters require that the current shall always pass through them in one direction and unless this obtains no deflection will take place. This condition is illustrated in Fig. 1, from which it will be evident that the current

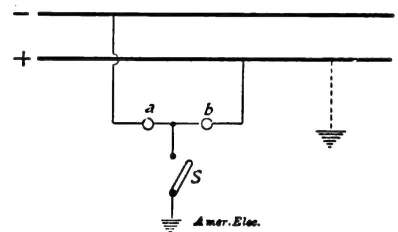

FIG. 3.

flows in opposite directions with the switch on contact 1 and on contact 2, and unless a double deflecting voltmeter is used a ground can only be detected on one main. To make such a voltmeter indicate grounds on both mains a special switch must be provided. The voltmeter can then serve the double purpose of a voltmeter and a ground detector. Fig. 2 shows such a switch. With the switch on contacts 1-1′ the voltmeter, which is a single-scale instrument, is connected across the line and indicates the voltage on the system. With the switch on contacts 3-3′ any ground on the negative wire will be detected, and with the switch on contacts 2-2′ grounds on the positive lead are indicated, the current always passing through the voltmeter in the same direction.

A very common arrangement for detecting grounds on a circuit in which incandescent electric lamps are used is shown diagrammatically in Fig. 3. The lamps are connected in series across the line, and the voltage of each lamp is the same as that of the generator, so that when placed in series the lamps merely burn with a dull red color. The ground connection is made through a switch, one end of which is connected to the wire between the lamps as indicated. When the circuit is closed at *S*, if no ground exists on either line, both lamps will still burn with a dull red glow. If the positive main is grounded, however, very little current will flow through the lamp *b*, since an easier path is provided through the lamp *a*, switch *S*, ground and thence to the negative main. In consequence the lamp *b*, which is thus shunted by the ground connection will be extinguished, and lamp *a* will receive the full potential of the circuit and burn at its rated candle-power. The lamp which becomes dim or entirely extinguished indicates that

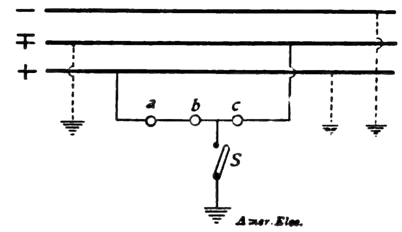

FIG. 4.

the ground is on the lead to which it is connected, while the brightly burning lamp indicates that the lead to which it is connected is clear.

For a three-wire system a modification shown in Fig. 4 is used. Here three lamps are connected across one side of the system. Connection is made with the ground through the switch, *S*. The lamps all burn with the same degree of brilliancy, a dull red, and if the switch is closed and the lines are free from grounds no change is noticeable. If, now, the positive main becomes grounded and the switch is closed, lamp *c* will be connected across the neutral and negative mains, and lamps *a* and *b* will be extinguished. Lamp *c* will consequently burn at full candle-power. Should the neutral become grounded, lamp *c* will be extinguished; but since lamps *a* and *b* are connected in series they will increase appreciably in brightness, but not burn at their rated candle-power. If a ground occurs on the negative main, all the lamps will burn at full candle-power, since lamp *c* is connected across the negative and neutral leads and lamps *a* and *b* are connected in series across the positive and

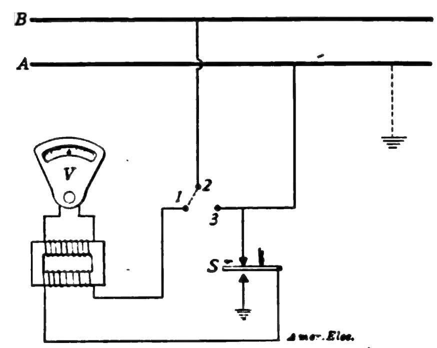

FIG. 5.

negative leads. By this means a ground on any of the three wires is positively indicated.

On alternating-current systems the same general scheme can also be employed to detect grounds, except that potential transformers are employed to step down the voltage so as to be suitable for the voltmeter or lamps, whichever may happen to be used. A diagram of connections for a system of this kind employing a double deflecting voltmeter is shown by Fig. 5. A plug switch is used to connect points

1 and 2 or 1 and 3 together. Ordinarily the primary of the potential transformer is connected across the line through points 1 and 2, so that the station voltmeter becomes available as a ground detector also.

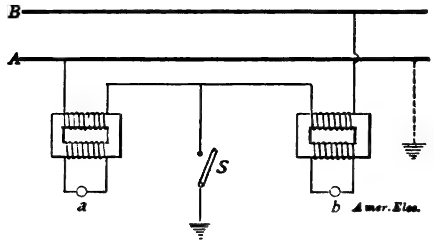

FIG. 6.

A switch, *S*, is used to connect one side of the line to the ground through the primary winding of the transformer. If now a ground occurs on the side of the line marked *A*, the voltmeter will so indicate, and the extent of the voltmeter deflection is a measure of the seriousness of the ground. By placing the plug so as to connect 1 and 3 the other side of the line may be tested. When the switch *S* is in its normal position, the voltmeter performs its normal function as a potential indicator.

For high-tension, alternating-current lines the type of detector shown in Fig. 6 is suitable. Incandescent electric lamps are used and the scheme operates like that shown in Fig. 3; the only difference being that the lamps are fed through transform-

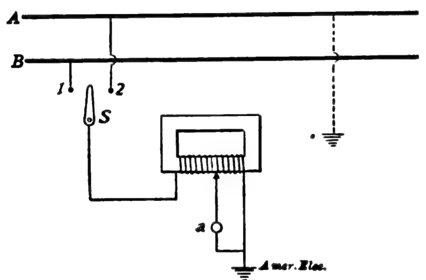

FIG. 7.

ers, the primary coils of which are connected in series across the high-tension mains. Another form of ground detector for high-tension, alternating-current lines, which operates like the detector shown in Fig. 1, is shown in Fig. 7. A coil of wire is wound on the laminated core of a transformer, and the lamp is connected to the grounded end of the coil and to an intermediate point of the coil as indicated. In case either side of the line is grounded current flows through the coil and an e.m.f. is set up between the points where the lamp is connected and the lamp is lighted.

In modern installations all of the alternating-current types of ground detectors already explained are giving place to ground detectors operating on the electrostatic principle. There are two types in general use, each of which will be described. The ground detector shown in Fig. 8 has four fixed vanes arranged around a movable vane of aluminum attached to a pointer. The fixed vanes are connected diagonally in pairs, and each pair is charged statically by one of the line wires through the medium of a condenser. The movable vane is connected to earth. The fixed vanes act inductively on the movable vane so that the stress produced by each pair is equal, but opposite. The movable vane consequently takes a position midway between the fixed vanes which position obtains whether the condensers are charged

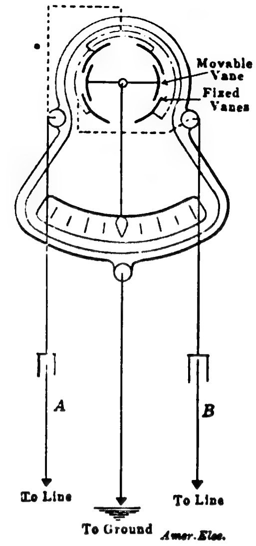

FIG. 8.

or not, so that the pointer rests at zero indicating no ground. Should a ground occur the primary plate of one of the condensers and the movable vane become connected electrically, and the pair of fixed vanes leading to that condenser assumes the polarity of the movable vane, repelling

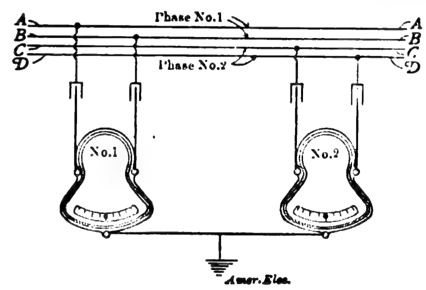

FIG. 9.

the latter. At the same time the other fixed vanes which are of opposite polarity attract. Since the two forces act in the same direction, the movable vane occupies a position within the vanes oppositely charged to it, and the pointer indicates a ground on the side of its deflection. The primary plates of the condensers are connected to the line, and the secondary plates to the fixed vanes of the instrument. The use of separate condensers for charging

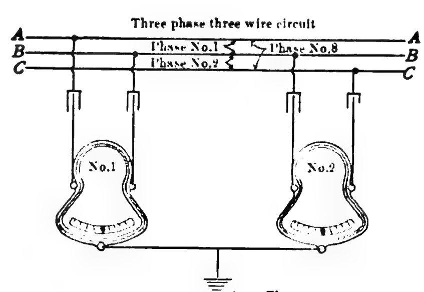

FIG. 10.

the fixed vanes keeps all high-potential currents away from the instruments and also has an advantage in that the instrument may be mounted wherever convenient without regard to the position of the line wires. The condensers may be located at or near the line wires and insulated from each other by as great a distance as may be deemed necessary.

Fig. 8 shows the detector connected to a

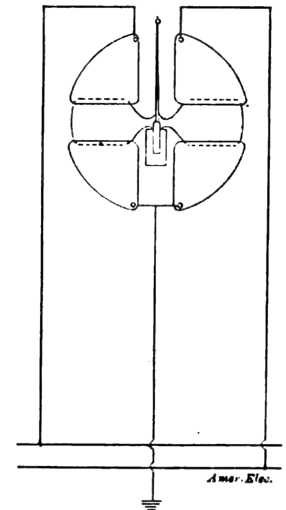

FIG. 11.

single-phase circuit. If a ground occurs in line *A* the pointer deflects to the left, and if the ground is on line *B* the pointer deflects to the right. Fig. 9 shows the connections for a two-phase, four-wire circuit. In this case two instruments are required. Should a ground occur on line *A* the pointer on instrument No. 1 would deflect to the left, and to the right if the ground were on line *B*. If a ground occurs on line *C* the pointer of instrument No. 2 would deflect to the left, and to the right if the ground were on line *D*. The connections for a three-wire, three-phase circuit are given in Fig. 10. With a ground on line *A* the pointer of instrument No. 1 would deflect to the left; with a ground on line *B* instrument No. 1 would deflect to the right, and instrument No. 2 would deflect to the left. Instrument No. 2 deflects to the right if a ground occurs on line *C*.

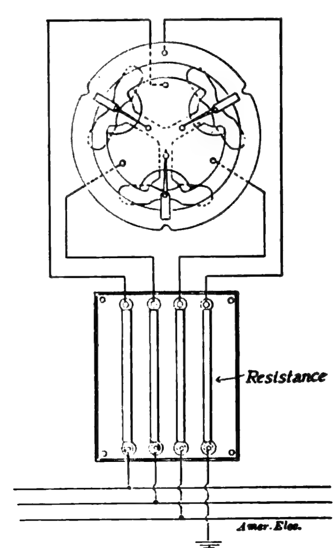

FIG. 12.

The electrostatic ground detector shown in Fig. 11 is similar in construction to the electrostatic voltmeter for laboratory use. The two lower quadrants are connected to ground and the two upper quadrants to the

lines. The vane with its pointer is pivoted at the center of the circle formed by the quadrants and rests normally at zero, lying across the shortest path between the positive and negative quadrants, the upper right and left. When either side of the line is grounded, the lower quadrants cease to be neutral, disturbing the balance of the system and the needle deflects to the right or left, depending on which side the ground occurs. The moving mechanism has no electrical connection with either side of the line or with the ground, and resistances are sometimes placed in series with the instrument. A three-phase ground detector is shown in Fig. 12. This is practically a combination of three single-phase instruments symmetrically arranged and enclosed in a case. When no ground exists the three needles point to zero, and when a ground occurs on one of the lines the two adjacent needles are deflected toward the segments to which the grounded line is connected. If a ground occurs on two lines the needle between the segments connected to the grounded lines will be deflected toward the one having the lower resistance ground and the two remaining ones will be deflected toward the grounded segments.

THE MISUSE OF SWITCHBOARD INSTRUMENTS.

BY K. S. HOWARD.

One of the most practical questions in connection with the operation of electric power plants is the use of the switchboard instruments. Unless such apparatus is properly treated the conclusions of the owners in the matter of operating expenses and economy are likely to go far astray from the truth. A poor instrument is worse than no instrument at all, when it comes to estimates of the cost of generating each unit of power output, and a good instrument mistreated is perhaps worse than either.

To secure the best results from one's instruments it is well to begin with their shipment from the factory. In most cases both time and money will be saved by shipping instruments by express instead of by freight, on account of the greater care which the express companies take in transporting such products. Instruments should never be shipped attached to the switchboard on which they are to be used. The reason for this is not far to seek, and as one manufacturer has well expressed it, "anyone who has ever spent a night on a marble slab in a freight car will understand why a small amount of paper and excelsior with a berth in an express car saves most of the tiring effects of travel." In foreign shipments the cases ought not to be opened until they reach the point of destination. Some makers ship instruments by water, enclosed in hermetically-sealed metal cases surrounded on the outside by wooden packing cases. It is almost impossible to reseal this kind of metal case after it has once been opened, and its use is necessary for the proper protection of the instrument from water.

When a consignment of instruments arrives at the plant it is poor practice to break the seals for the purpose of getting acquainted with the interior construction of the different types. The idea prevails in some quarters that seals are provided simply to protect the instrument maker, but as a matter of fact they also protect the user, and in cases where the latter is not at fault the unbroken seal places the responsibility for repairs or replacement upon the manufacturer. No sensible engineer can reasonably expect an instrument maker to assume responsibility for performance when the seal is broken and the apparatus injured by unskilled tinkering. An examination of any instrument by its maker almost always enables him to tell at once why the apparatus did not operate and whether the trouble is due to defective material, poor workmanship or misuse on the part of a customer.

The proper location of switchboards is a question of much importance, for it is highly desirable to avoid the influence of external magnetic fields and to mount the panels on solid foundations entirely separate from the foundations of the machinery. If any perceptible vibration is transmitted to a switchboard the instruments may easily receive more wear in a single day than in many months of service on a steady set of panels.

In mounting series ammeters care should be taken to see that the leads do not form a loop within which the voltmeter or any other instrument will be located. Cases have occurred where the ammeters were located at the top of the switchboard, with leads from the circuit-breaker and main switch running up on each side, forming a loop or solenoid within which the voltmeter was mounted. With a flow of current varying from 0 to 1200 amperes this construction means that the voltmeter is subject to a varying field which may act with or against its own field with an intensity of 1200 ampere-turns. Such a field is probably much more intense than the field within the instrument itself; hence it cannot be expected that the instrument will indicate correctly, for no magnetic shield can be provided which will protect it from such a powerful external field.

There is little sense in mounting instruments 8 or 9 feet above the floor line and expecting attendants of normal height to be able to read them. As one instrument maker has cogently remarked, "Eight-foot attendants are scarce and expensive." Nor is it a good plan to mount instruments upside down, or to place them on top of excited dynamos or motors. The practice of chiseling out holes in a switchboard and riveting up the frame after the instruments are attached is almost certain to result in broken jewels. Rough usage of any kind, even if an instrument is securely held in its box, is inexcusable. If through accident or carelessness an instrument is dropped, it should be calibrated before being used in any service where accurate indications are of consequence. A gentle tapping of the case with the finger should be the extreme method of adjusting an instrument by force, and it is always well to make sure that the leads are connected to the proper terminals and that the pointer stop is released before attempting to place an instrument in service. Contacts ought to be cleaned thoroughly at the start, set up tight and kept free from looseness, dirt and grease if good results are desired. There is little to be gained from polishing a plated instrument daily with sand soap or emery. In using either a switchboard or a portable instrument it is well not to rub the glass which covers the scale before taking a reading, on account of the static charges which such a rubbing induces in the moving parts. These charges interfere with the accuracy of the reading, but can easily be dissipated by lightly touching the glass above the needle with the finger, when the pointer will return to the zero position. Overloading an instrument beyond its maximum scale reading opens the way toward poor satisfaction with its behavior, as does leaving in circuit instruments designed for intermittent use. When properly treated, electrical instruments require little attention beyond occasional calibration, and their maintenance expense should be nominal. High precision is attained, even in many switchboard instruments now on the market, but unless reasonable care is taken to avoid abusing such apparatus the money expended to secure accuracy is largely wasted.

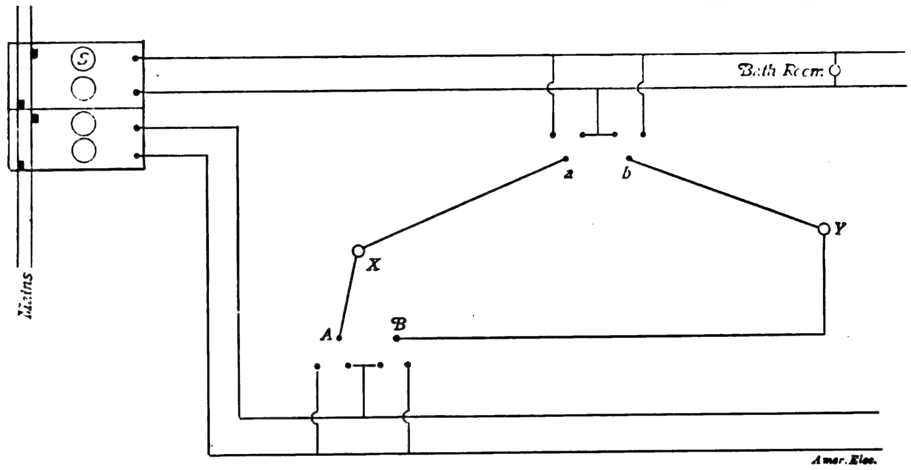
Letters on Practical Subjects

Communications intended for publication in this department must be received at this office not later than the 15th of the month prior to the date of publication.

Reversing the Polarity of Generators.

I find the many practical letters and other articles published in your paper a very great help to me, and just what an engineer needs to steer him through the many and trying problems that come up. I believe every man who has charge of engine and boiler rooms should have near him a reference of some kind so that when trouble occurs he may refer to it for a remedy, and for that reason a single number of the AMERICAN ELECTRICIAN should not be missing from his desk. Having had considerable trouble at one time with generators which reversed their polarity, I feel that perhaps the remedies I dug out may be interesting to my fellow readers. There are three methods which might be followed in exciting the fields when generators have become reversed in polarity. Method 1 is used when a machine fails to build up or has become reversed, and both bus-bars are alive through connection with some other station. Method 2 is used when, through the grounding of an armature of one machine, a blow-out occurs with the other machines on the line, so that all be-

come reversed; a tie connection with another station keeping the bus-bars alive, Method 3 is followed when all the available generators have become reversed and the bus-bars are not alive. When using the first method, before separately exciting the machine, the shunt field coil should be tested in order to ascertain whether there is an open circuit in it or not. To sepa-



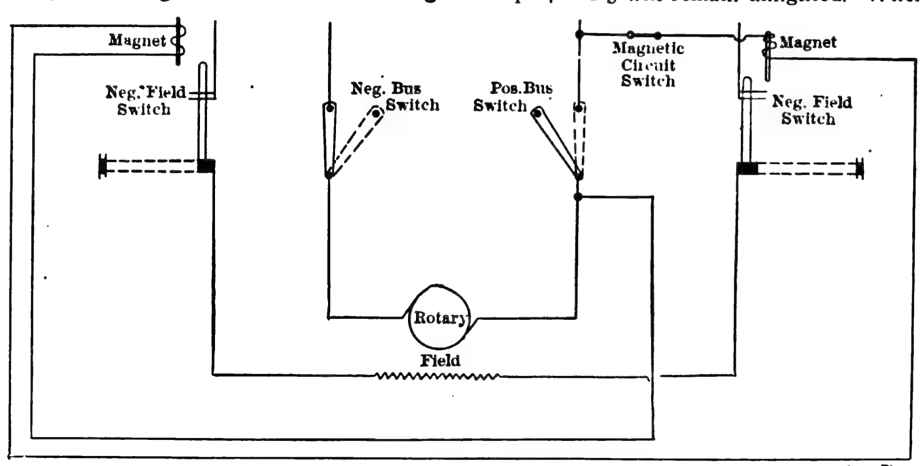
SOLUTION TO MR. HARTMAN'S PROBLEM IN HOUSE WIRING.

rately excite the machine the procedure is as follows: (1) Put one or more machines which are not reversed on the line in regular service. (2) Close the equalizer circuit of the machines and also the equalizer switch of the defective machine. (3) Close the positive switch of the defective machine and after these switches have remained closed for a few seconds open the positive and equalizer switch of the machine which was separately excited and this machine may then be started and built up in the regular manner. If a defective machine is running during the time that it is desired to reverse its polarity, the shunt field switch should be opened before closing the above-mentioned switches. Then a few seconds after these switches are closed, the field switch may be closed, and the machine should then build up as usual. When using Method 2, the engineer should proceed as follows: (1) Open the field switch of the machine it is intended to separately excite. (2) Pull out one of the wires from the binding post as a precaution. (3) Cut out about one-half of the field resistance. (4) Close the positive switch of the generator. (5) By means of a wire connect the pivot of the field switch back of the board with the ground. It is preferable to have a fuse in circuit with this wire. (6) After this connection has been made for a few seconds, remove it, slowing drawing out an arc while so doing. (7) Reinsert the wire in the binding post and build up the machine in the usual manner. If one or more machines still remain reversed change them back to normal by Method 1, putting the machine just given its right polarity back in service on the line. In using Method 3, in order to obtain a source from which to excite the fields of the other machines, build up one of the reversed machines and proceed as follows: (1) Open the field switch of the machine to be separately excited. (2) Remove the wire from the binding post of this machine. (3) Make a connection back of the board by means of a wire between the lower stud of the normal negative switch of the machine which has been built up in the reversed direction and the lower stud of the normal positive switch of the machine which it is desired to separately excite. (4) As a precautionary measure connect a fuse between the lower stud of the normal positive switch of the machine which is reversed and the pivot of the field switch of the machine it is desired to separately excite. (5) After the connection has been made for a few seconds remove the connecting wire slowly drawing out an arc during the removal. (6) Insert the wire in the binding post again and build up the machine in the usual manner.

Cambridge, Mass. W. A. Dow.

Field Circuit Control.

In enclose herewith a diagram by means of which the opening of the field circuit of a machine is prevented while the machine is in operation. Referring to Fig. 1, in which the rotary converter is represented as stopped, it is evident that when the rotary is running the armatures of the mag-



FIELD CIRCUIT CONTROL.

nets drop by gravity and prevent the field switches from being opened. When the positive bus switch is opened the rotary will gradually come to a standstill, and after it has stopped the magnets will be energized and will lift their armatures, thereby permitting the field switches to be opened.

New York City, N. Y. A. J. DUNLOP.

Mr. Hartman's Problem in House Wiring.

No solutions were received for Mr. Hartman's problem in house wiring as published in the November number, and since his trouble was due to a trifling defect in the fuse plug, and not to any error in the wiring connections, the problem might be deemed unfair. We have received many diagrams of connections, which with perfect fuse plugs would overcome the defective lighting; but the problem did not call for the connections. Fig. 1 shows the correct diagram of connections as given by the author of the problem, and also shows where the trouble was found. A piece of solder in the fuse plug *S* would not allow the plug to make contact.

Mr. Simon's Problem in Arc Lamp Wiring.

Enclosed is a solution of Mr. Simon's arc lamp problem published in the November

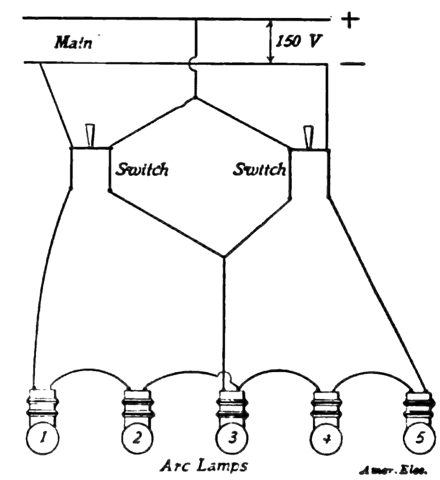


FIG. 2.—MR. MAURY'S SOLUTION.

number. 1, 2, 3, 4 and 5 are 35-volt series arc lamps, and *E* is a two-way switch. With the switch in the position shown, lamps 1, 2 and 3 will be lighted while lamps 4 and 5 will remain unlighted. When the switch is in the position indicated by the dotted lines, lamps 3, 4 and 5 will light and lamps 1 and 2 will be extinguished.

Greensburg, Pa. J. HARVEY BUTLER.

As a solution to Mr. Simon's problem in arc lamp connections, I submit the accompanying diagram (Fig. 2). If desired three single-pole switches or three plug

switches may be used in place of the two two-pole switches shown.

Rossville, Ill. JACK MAURY.

[Similar solutions were also received from F. A. Cocker, Salem, Mass.; E. C.

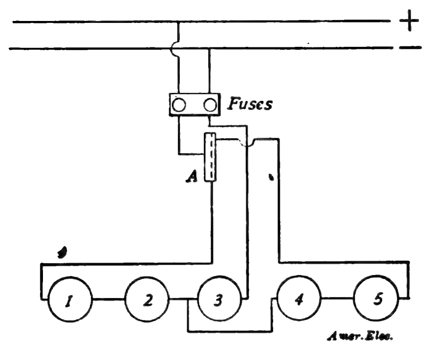

FIG. 3.—MR. ROWLEY'S SOLUTION.

Daggett, London, Tenn.; J. K. Kates, H. F. McCullough, Wilkinsburg, Pa.; and N. C. Pervier, Cedar Rapids, Ia.—EDITOR.]

I enclose herewith a solution to Mr. Simon's problem published in the November number. Switch *A* may be either a single-pole, double-throw knife switch or a two-way snap switch.

Syracuse, N. Y. C. A. ROWLEY.

[Similar solutions were also received from C. F. Abele, New York City; R. F. Becker, Marquette, Mich.; C. D. Bowman. Chicago, Ill.; F. B. Bremer, Toledo, Ohio; L. W. Duncan, Chicago, Ill.; F. J. Cummings,, Devils Lake, N. D.; W. H. Hufft, Excelsior Springs, Mo.; D. C. McMeehan, Victor, Colo.; J. L. Remaley, Schickshinny, Pa.; J. C. Runyon, Rahway, N. J.; E. J. Schuetzler, San Francisco, Cal., and J. F. Smith, Anderson, Ind.—EDITOR.]

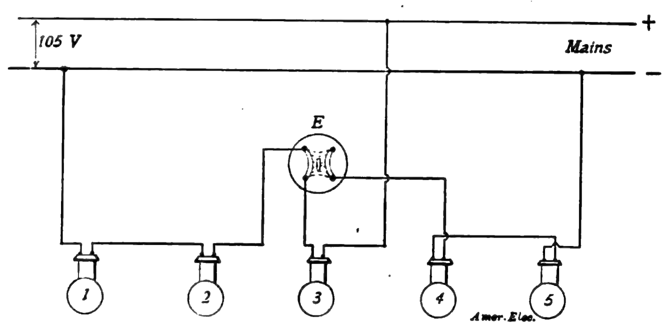

FIG. 1.—MR. BUTLER'S SOLUTION.

The lamp problem offered by Mr. Simon in the November issue may be readily solved as indicated in Fig. 4, which shows how five series arc lamps might be connected so that lamp No. 3 will operate with lamps No. 1 and No. 2 or with lamps No. 4 and No. 5; each lamp requiring 35 volts and the combination of three lamps in series being thrown across the 105-volt mains.

West Lynn, Mass. DUNKLE A. PURCELL.

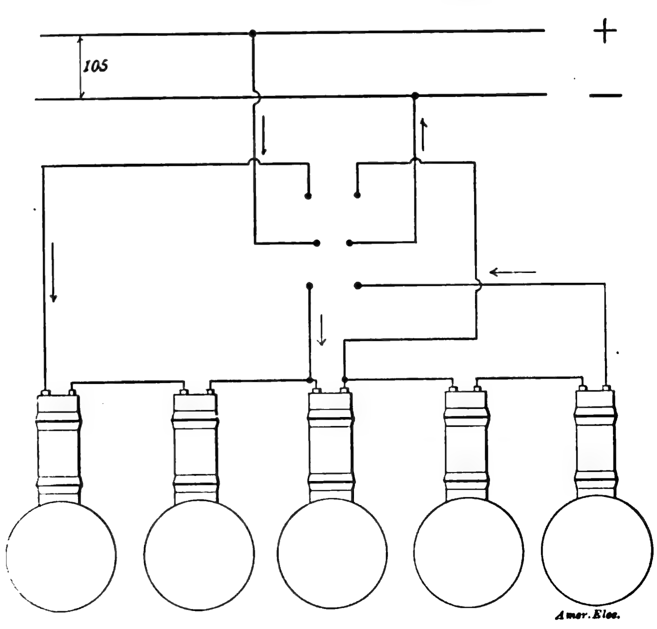

FIG. 4.—MR. PURCELL'S SOLUTION.

[Mr. Purcell's solution is similar to Mr. Simon's. Similar solutions were received from F. A. Bunks, St. Joseph, Mich.; S. J. Chapman, Wabash, Ind.; C. J. Corse, State College, Pa.; W. L. Diffendorf, Akron, Ohio; J. B. Dillon, Louisville, Ky.; W. K. Dimock, Brooklyn, N. Y.; S. Eisner, New York City; J. D. Elder, Detroit, Mich.; O. B. Eve, Augusta, Ga.; H. A. Fiske, Kingston, R. I.; L. J. Gorilla, Ironwood, Mich.; C. M. Hamilton, Charlotte, N. C.; O. Hood, Martinsville, Ind.; C. H. Jarvis, Charlotte, Mich.; E. S. Lincoln, Brookline, Mass.; A. F. Lippincott, Spokane, Wash.; H. E. Maxson, Scranton, Pa.; S. G. FacFadden, Monterey, Mex.; R. McDaniel, Port Arthur, Tex.; C. H. Morrison, San Matio, Cal.; C. W. Petry, Washington, D. C.; J. F. Post, New Haven, Conn.; W. H. Spahn, Brooklyn, N. Y.; R. Q. Swaffield, Elkhart, Ind.; A. H. Sweetnam, Chicago, Ill.; A. Weinberg, Zanesville, Ohio; and J. R. Wilson, Pottsville, Pa.—EDITOR.]

Fighting a Gas Franchise.

Your readers will doubtless be interested in the manner in which the local lighting company here succeeded in keeping gas out of Maryville, despite the fact that the whole political organization and the press were in favor of such a plant. The lighting company was charging $8 a month each for arc lamps and $2 a month each for 32-c.p. incandescent lamps, lighting the city hall free of charge. When the contract expired the company was notified that if it continued its lighting it would receive only $7 for each arc light. Meanwhile the city council were becoming interested in gas, and the *Daily Tribune* was boiling with enthusiasm over gas. Not being able to supply the lights at the price offered, the company shut off the street lighting service at the expiration of its contract, and the city was left in darkness for about ten days, when an agreement was reached whereby the old price would be paid until some other arrangement could be effected. Shortly afterwards, a request was made by a Chicago capitalist for a franchise to build a $70,000 coal gas plant. This request was evidently to the liking of the council, for they immediately went into executive session, passing an ordinance and also signing a secret agreement whereby they pledged the city to enter into a ten-year contract with the gas company ten days after the ratification of the ordinance, to light the city with gas mantle lamps at the rate of $3,500 a year. A special election was called to vote on this ordinance, the context of which, by the way, was never communicated to the public. The election notice concluded with the statement: "If you vote YES it will be taken by the board that you have assented to the granting of the franchise in the manner and form and according to all the provisions provided by said ordinance." The press being hostile to the interests of the electric light company, the only way in which the latter concern could obtain the ear of the public was through the publication of a separate paper.

The company accordingly published a four-page paper, which they called the *Daily Gas News,* in which it was clearly pointed out that the company was not in any fear of competition, and was not fighting a reasonable franchise, but merely the plan of the politicians to wrest from the city an outrageous contract in an illegal manner. Only four issues of the *Daily Gas News* were required to thwart the scheme of the politicians, for matters became so hot that the Chicago capitalist withdrew his proposition. The result is there is no gas in Maryville.

Maryville, Mo. RICHARD PECK.

Questions and Answers

Inquiries not accompanied by the name and address of the inquirer, will not receive attention.

Can a three-phase induction motor be run as a generator? G. A. P.

Yes, if it is driven above synchronous speed and has its field excited from an alternating-current source.

In connecting an indicating instrument to a switchboard carrying a low potential alternating current, should series transformers be used? R. S.

The use of series transformers even on circuits of comparatively low potential seems to be increasing. The added convenience in removing or cutting out instruments for recalibration and the added security for the switchboard operator, more than compensate for the slight error introduced by their use.

Which would give better service, two engines of 8 and 9 horse-power respectively coupled to one shaft, or one engine of 17 horse-power? M. D.

A 17-h.p. engine would be the more economical. The mechanical efficiency or ratio of the delivered horse-power to the indicated horse-power decreases very rapidly as the size of the engine decreases. The friction loss and loss by condensation in an 8-h.p. engine and a 9-h.p. engine would exceed considerably the corresponding loss in a 17-h.p. engine.

I am using woven-wire brushes on a shunt-wound bipolar dynamo generating 350 amperes at 110 volts. I have always had considerable trouble with sparking and desire to change the brushes for something better. Would carbon brushes answer? H. R. L.

Carbon brushes would undoubtedly give better service as regards sparking, but it is hardly practicable to use them in this case because they would run too hot, the collecting surface of the commutator being designed for copper brushes. You might try a set of high-resistance brushes.

What is the difference between a starting rheostat and a rheostat for controlling the speed of a motor? N. Y. C.

A rheostat for controlling the speed of a motor does not differ in general construction from a starting rheostat. The main difference is that the regulating rheostat must be capable of carrying current continuously without overheating, whereas a starting rheostat is designed to carry current for a short time only. A regulating rheostat has, therefore, to be much larger than a starting rheostat.

How may I make a horseshoe magnet? K. S. L.

Horseshoe magnets are made of steel similar to that used for making edged tools. Tungsten steel is the best for the purpose. The bar of steel is first bent to shape and then hardened. The steel should be so hard that a file will make little impression on it. After the steel is hardened, it may be magnetized either by bringing it in contact with a powerful magnet, such as the pole-pieces of a dynamo, or by winding a coil of wire around each leg of the horseshoe and sending a strong current through the coil.

What causes a 20-kw. 220-volt direct-current dynamo to at times send out a small ring of sparks which completely encircle the commutator. This occurs usually on the commutator face about one inch from the outside end, but sometimes shows the same distance from the other end. Commutator compound usually starts this stream of sparks. The commutator is in fine condition and the machine does not give trouble otherwise. N. M.

The sparking is probably due to particles of dirt that bridge over between the commutator bars. Commutator compound usually contains graphite and particles of this will cause these fine sparks by connecting adjacent bars and by drawing out small arcs from the brushes. These fine sparks are not harmful nor do they indicate any defect in the machine. They are common where carbon brushes are used, and if the commutator is occasionally wiped off will be greatly reduced.

A 250-light generator operating at 125 volts has been used three years. The commutator is in good condition and the machine is not overloaded. Carbon brushes are used and one of them gives a great deal of trouble; it gets very hot and burns away after a few days' use. How may I remedy this trouble? A. S. M.

Since the machine is not overloaded the excessive heating of the brush is probably due to improper commutation. The brushes may be located so that there is an excessive current in the coil under commutation at the moment it is short-circuited by the brush. Try rocking the brushes back a little, if this can be done without sparking. If the brush has too low a resistance, excessive current may flow through it during commutation and this may account for your trouble.

How can I change the direction of rotation of a shunt-wound motor, of a series-wound motor and of a compound-wound motor? What is the effect of weakening the field of a shunt-wound motor, and also of a series-wound motor? Why? E. M.

The direction of rotation of a motor may be changed by reversing the current either through the armature or through the field coils; but not through both. If both are changed the motor will run in the same direction as it did before the change was made. Weakening the field of a shunt-wound or of a series-wound motor would result in an increase in speed in both cases. Since the counter e.m.f. of a motor is directly proportional to the number of lines of force cut, the armature must revolve more rapidly with a weakened field in order to generate the necessary counter e.m.f.

Is it possible to obtain a two-phase current from a three-phase current by using three-transformers? I have a three-phase generator and testing board and would like to have this equipped for two-phase work if possible. C. P.

You can obtain two-phase current from a three-phase line by the use of three transformers; but two transformers would answer, and would be preferable. These may be connected according to the Scott method. The primary of the first transformer is connected to the center of the primary of the second transformer, and the number of turns on the secondary of the first transformer should be $2 \div \sqrt{3}$ times the number of turns on the secondary of the second transformer, the primary turns of both transformers being equal in number.

When installing transformers in districts how much greater capacity than needed should be provided for probable increase in load? S. E.

This is rather difficult to answer. There are two ways in which unnecessarily large transformers cause a loss to central stations: 1. Interest and depreciation on the extra investment involved. 2. Increased core loss. The total yearly loss per kilowatt of surplus transformer capacity varies with average size transformers from \$3 to \$4. The only way to gauge the maximum load on a line to which a transformer is connected is to place a demand indicator in series with the transformer, connecting it to the secondary of the transformer, unless this is large, in which case it should be connected to the primary. The maximum load being thus made known it is then a question depending on the conditions whether or not to install a larger transformer. The transformer will stand a continuous overload and probably this overload capacity will be sufficient to take care of the increased demand for some time; or the demand indicator may be left in circuit permanently and no increase in transformer capacity provided until the demand indicator would so indicate.

Will a current-transformer of a certain capacity and a known ratio of transformation used with an indicating wattmeter give a true reading using the formula, ratio of current transformer times wattmeter reading equals true watts? W. W.

No. Instrument transformers do not correctly perform their function of delivering to the meter those fractions of line pressure and of line current called for by their ratios. The pressure delivered from the secondary coils of a pressure transformer will vary with the amount of load that is put upon the transformer by reason of the impedance drop in its coils. Where wattmeters are supplied through a transformer phase displacement between the primary and secondary electromotive forces takes place. The error in the case of a current transformer arises not directly on account of the impedance of the coils, but because not all of the primary current is transformed, part being used to magnetize the core. When this component is subtracted vectorially, the remainder is transformed at the true ratio. Consequently two errors are introduced: the quantity of secondary current is too small, unless the ratio of the transformer is changed by removing the proper number of turns from the secondary coil; and the phase of the secondary current is different from the phase of its primary. You will find this matter fully discussed in a paper read before the American Institute of Electrical Engineers by J. D. Nies; the title of the paper being "Some Notes on Polyphase Metering." This paper is printed in the April, 1905, *Proceedings of the American Institute of Electrical Engineers.*

New Apparatus and Appliances

REVERSIBLE SINGLE WIRE CLEAT.

Figs. 1, 2 and 3 show a new form of single wire cleat brought out by H. D. Murdock, of Pittsburg, Pa. A particular

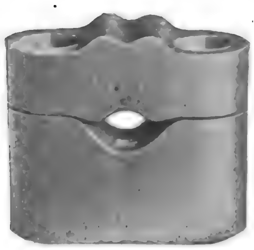

FIG. 1.—REVERSIBLE WIRE CLEAT.

feature of this cleat is the reversible top by means of which two different sizes of cleats in combination with a bottom piece

FIG. 2.—REVERSIBLE WIRE CLEAT.

may be formed. Two bottom pieces can also be combined to form a larger cleat, as indicated in Fig. 3. By knocking out a small rosette in the bottom piece a screw

FIG. 3.—REVERSIBLE WIRE CLEAT.

or tack can be used to hold the bottom independent of the top.

DOUBLE-JOINT DESK FIXTURES.

The accompanying illustrations show a

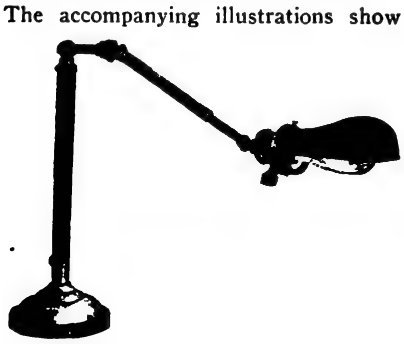

FIG. 4.—DOUBLE-JOINT DESK PORTABLE.

new line of double-joint desk fixtures placed on the market by McLeod, Ward & Co., of New York City. As the name implies, there is a double-joint movement near the base, and a single-joint movement at the socket, enabling a light to be placed at any point desired within the range of the fixture without loosening or tightening screws. The joints are so constructed that they may be moved freely without straining or in any way injuring the flexible plate which is concealed in the tubes. One style of these fixtures is arranged with two brass clamps, which can be fitted over a roll-top desk and then tightened in place, making a perfectly rigid fixture. Another style is arranged with a back clamp similar to that used on the Kinsman desk lamp, which has an adjustable front clamp. The fixtures

FIG. 5.—FIXTURE FOR ROLL-TOP DESK.

are all fitted with telescoping tubes similar to those used in the well known Kinsman desk fixtures. This makes them suitable for small or large desks. The fixtures are well constructed, and with the old line of desk fixtures manufactured by the company cover the lighting field pretty thoroughly.

IMPROVED GATE VALVE.

The Lunkenheimer Company, of Cincinnati, Ohio, has brought out the gate valve shown in section by Fig. 6 herewith, which, it is claimed, embodies many improvements. The valves are made of iron with bronze trimmings, in three different weights for working pressures of 125, 150 and 250 pounds per square inch, and are also made in bronze for 150 and 250 pounds pressure. The valves are made with stationary stem or with outside screw and yoke. The seat rings as well as the wedge

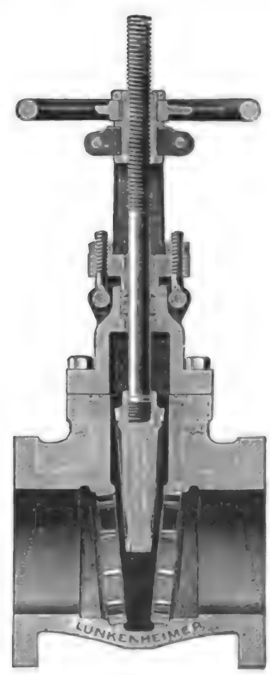

FIG. 6.—GATE VALVE.

disc, may be renewed when worn. That portion of the valve body which receives the seat rings is threaded to the angle of the tapers of the valve disc. The seat rings are also threaded and faced off straight and when screwed in place are said to fit accurately the tapers of the disc. The disc in both forms of valve is made of bronze up to and including the 6-in. size, above which they are made of iron with bronze seat trimmings. These rings are forced on the disc, a flange on the ring being flared out in a groove cut at an angle in the iron disc. There is thus no danger of the rings dropping off. Either pattern of the gate valves can be packed under pressure when wide open. The stuffing box in the valve with the stationary stem, is made of bronze, and is tightly screwed into the hub. In the valves with outside screw and yoke both the gland and stuffing box are lined with bronze bushings. The discs are accurately guided in the bodies, and by means of the guides, the stems are relieved of all side strains, which have a tendency to wear out threads. The stems in both forms of valves are made of rolled tobin bronze. All parts of the valve are heavy and compact, and the valves are not affected to any appreciable extent by expansion or contraction.

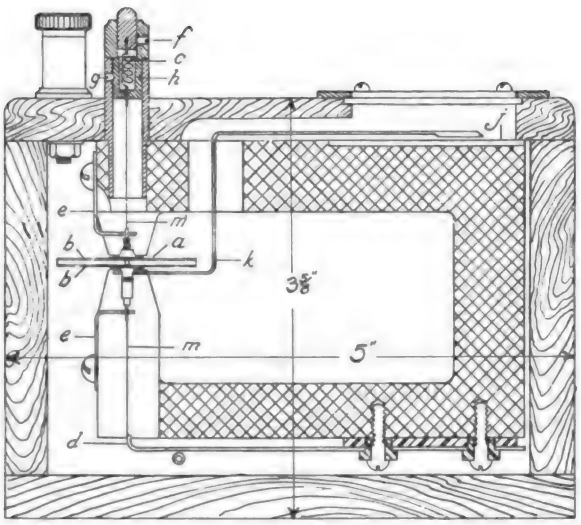
PORTABLE MOVING COIL GALVANOMETER.

The Leeds & Northrup Company, of Philadelphia, has brought out the portable moving coil galvanometer shown herewith, a novel distinguishing feature of which is the method of suspending and winding the moving system. The suspension consists of upper and lower filaments, and in this particular differs from the pivot and jewel ordinarily used in instruments of the portable type. The magnetic field is produced by a U-shaped cast iron permanent magnet having inwardly directed poles at one end so as to have north polarity only on one

FIG. 7.—PORTABLE GALVANOMETER.

side of the air gap separating the poles and south polarity only on the other side of the air gap. The magnet is slotted so as to accommodate the moving system. The air gap between the poles being very short, the

field is uniform and intense. The moving system consists of four flat coils of very fine wire wound alternately in opposite directions, so as to produce alternate north and south poles when viewed from one side.



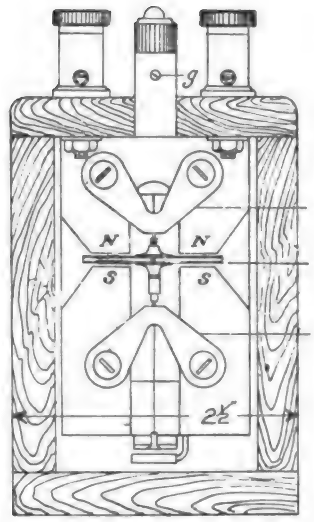


FIG. 8.—PORTABLE GALVANOMETER.—FIG. 9.

These coils are held between two aluminum disks, *b,* and suspended in such a manner that normally only a portion of each coil extends into the air gap between the magnet poles, though at all times only about one-half of the coil surface is between the pole faces. It is evident, therefore, that when current is passed through the coils two of the coils of like polarity will then swing around to inclose the greatest number of lines of force, while the other two coils of like polarity will be repelled. The aluminum discs, *b,* also serve the purpose of damping the system and rendering it dead-beat. The galvanometer can be given a high, medium or low resistance by connecting the coils in series, series-parallel or parallel. The suspensions consist of three wire filaments. To give the entire system resiliency in the event of sudden jars, the upper suspension terminates in a spiral spring, *c,* and the lower suspension is attached to a long flat phosphor bronze spring, *d.* An additional protection against excessive strains on the moving system is provided by means of two guards, *E.* These guards have clearance holes to provide for the rotation of the system, but limit the sidewise movement or play of the system, thereby arresting the movement of the coil due to any sudden shock. The movement of the system vertically is limited by the pole-faces of the magnet. The torsion head, *f,* provides a delicate zero adjustment and by means of the screw, *g,* operating in an annular groove, *h,* engages the end of the groove and thus acts as a stop to limit the extent to which the torsion head may be turned. The magnet with its complete moving system and scale is mounted in a highly polished mahogany case having a circular opening in the top protected by a glass window for the scale. The binding posts are securely mounted as indicated and are arranged to clamp large or small wires. The outside dimensions of the case are 5 ins. by 2½ ins. by 3½ ins. high.

WESTINGHOUSE "TYPE C" TRANSFORMERS.

The Westinghouse Electric & Manufacturing Company has placed upon the market a new line of core type transformers known as Type C. The transformers have operating characteristics closely approximating those of Westinghouse type O. D. transformers, and are intended for general distribution service on 60-cycle circuits operating nominally at 1,050 and 2,100 volts, although they will operate successfully on

FIG. 10.—FRONT VIEW OF TRANSFORMER.

voltages up to 1,200 and 2,400. They are manufactured in sizes from .6 to 50 kilowatts and are divided into classes according to the voltages of the secondary. Class 200 may be connected for either 105 or 210 volts, and class 400 for 210 or 420 volts. The transformer is enclosed in a cast iron case with felt gaskets under the lid, so as to make the transformer absolutely weather-proof. For sizes above 20 kilowatts the case is corrugated to increase the radiating surface. Hanger irons are provided by which any transformer up to and including 30 kilowatts may be mounted on a pole. The core of a type C transformer is built up of carefully annealed steel punchings. The primary and secondary coils are placed on the long sides of the core, the laminations of which are clamped together at top and bottom by suitable end frames. The low-tension winding is composed of one coil per leg, each coil having two sections so connected that the inner section of one leg is in series with the outer section of the other leg. This arrangement results in a

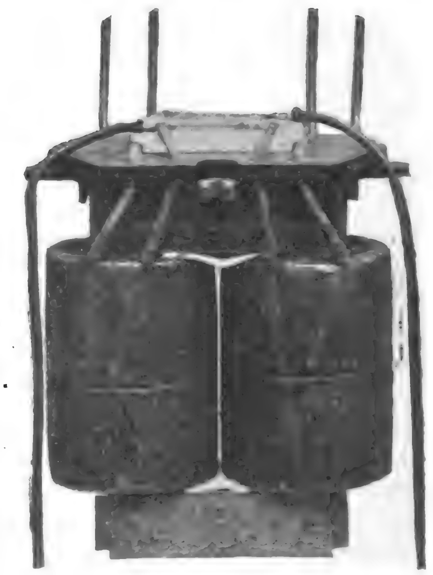

FIG. 11.—INTERIOR VIEW OF TRANSFORMER.

secondary winding of two similar parts both as to resistance and reactance, and insures equal loading of each primary coil irrespective of the method of loading the secondary. A balanced voltage is thus maintained on the two sides of a three-wire distributing system irrespective of the load. The high-tension winding is divided into two coils per leg to reduce the voltage between layers of the winding to a low value. The construction allows the use of a circular coil, which has many advantages. All insulating parts between layers of the winding and between high and low tension coils are cylindrical in form, eliminating sharp corners, which are harmful to insulating material. The windings are so disposed and oil ducts so provided that a free circulation of oil between coils and core is obtained, insuring ready dissipation of the heat and preventing deterioration of the insulation. Very careful attention has been paid to the insulation and liberal allowances made to insure a high factor of safety. All coils are wound to exact di-

FIG. 12.—REAR VIEW OF TRANSFORMER.

mensions and all insulation is cut to gauge, so that corresponding parts of all transformers of the same capacity are interchangeable.

OTIS FEED-WATER HEATER.

Fig. 13 herewith shows a patented feed-water heater recently introduced by the Stewart Heater Company, of Buffalo, N. Y. Fig. 14 is a vertical section of the oil separator and water chamber in line 2-2, Fig. 13, and Fig. 15 is a similar section with the baffle plates omitted. A fragmentary transverse section of one of the baffle plates is shown in Fig. 16. Refer-

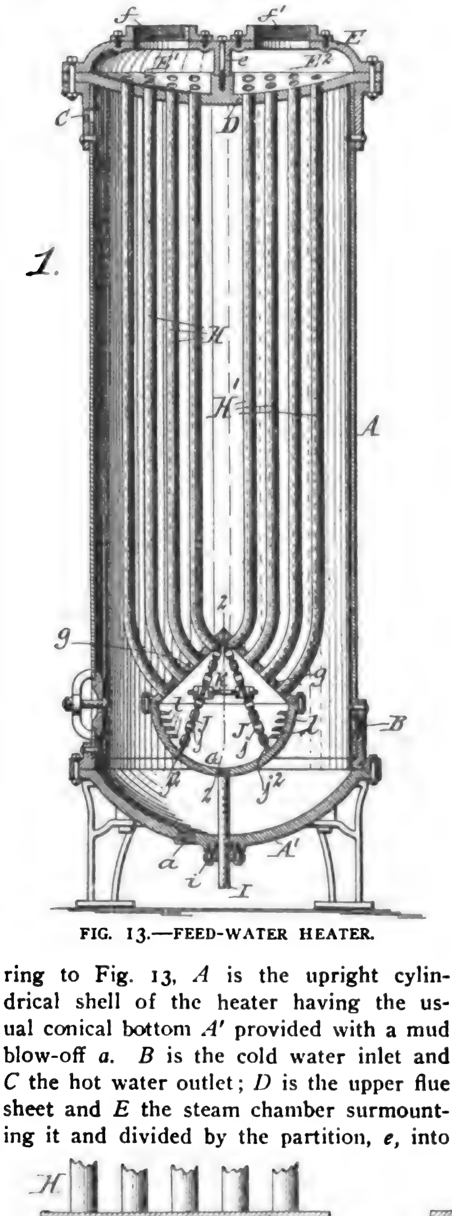

FIG. 13.—FEED-WATER HEATER.

ring to Fig. 13, *A* is the upright cylindrical shell of the heater having the usual conical bottom *A'* provided with a mud blow-off *a*. *B* is the cold water inlet and *C* the hot water outlet; *D* is the upper flue sheet and *E* the steam chamber surmounting it and divided by the partition, *e*, into

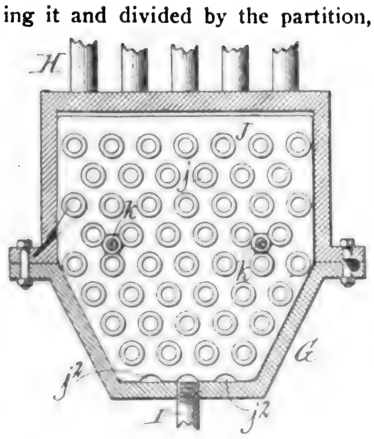

FIG. 14.

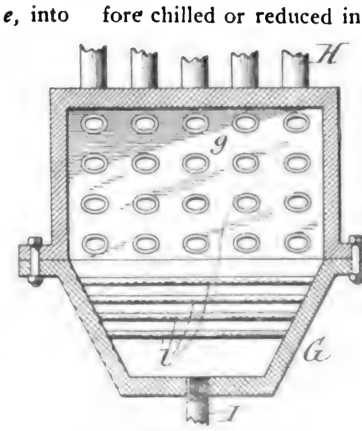

FIG. 15.

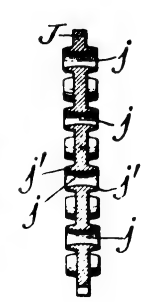

FIG. 16.

the inlet and outlet compartments, *E'* and *E''*, respectively; *G* is the water chamber and *HH'* are the two groups of tubes; *I* is a drain pipe for the oil and condensation. *JJ* indicate a pair of perforated baffle plates arranged in the chamber *G* so that the exhaust steam entering the chamber is compelled to pass through the openings, *j*, before escaping through the other set. The baffle plates are provided with openings over practically their entire surface, and each opening is bounded by a guard rim, flange, or nipple, *j'*, as shown in Fig. 16. In the engraving two baffle plates are shown; these rest upon the bottom of the chamber *G* while their upper ends are arranged in the apex of the angle formed by the inclined flue sheets *g*. The plates are provided with notches, j^2, to permit the passage of oil and water from the portion of the chamber *G* on the outer sides of the plates to the central portion. The plates are held in their proper positions by tie-bolts, *k*. A series of horizontal baffle ribs, *l*, project inwardly from the sides of the chamber. These ribs prevent the steam from carrying the oil and water of condensation through the ascending series of flues *H'*.

In the use of the apparatus the exhaust-steam entering the inlet-compartment *E'* descends through the tubes, *H*, into the oil and water chamber *G*, passes through the openings of the baffle-plates, *J*, and ascends thence through the tubes, *H'*, into the outlet compartment, E^2, from which the uncondensed residue of the exhaust-steam escapes through the outlet *f'*. Any oil carried over from the engine-cylinder with the exhaust-steam flows down the faces of the baffle-plates and collects in the lower portion of the chamber *G*, whence it is discharged through the waste-pipe, *I*, the oil deposited upon the baffle-plates being prevented from running through their openings by the guard-flanges, *j'*. To facilitate the dripping of the oil from these flanges, they are tapered toward their outer ends, as shown in Fig. 16. The chamber, *G*, forms a casing for the oil-separator, as well as a water collecting or condensation chamber. As this chamber is located in the lower portion of the shell or opposite the cold-water inlet, where its contents are coolest, the chamber and the baffle-plates, *J*, remain comparatively cool, and the oil contained in the steam is therefore chilled or reduced in temperature upon entering the chamber, thus greatly promoting its separation from the steam. By thus combining the oil-separator with the cooled condensation-chamber the oil is said to be extracted so thoroughly that the uncondensed residue of the exhaust-steam can be used for other heating purposes. By arranging the guard-flanges, *j'*, of the openings, *j*, on both sides of the baffle-plates the latter will intercept the oil from either side of the chamber, *G*, thus permitting the pipe connections to the steam-inlet, *f*, and outlet, *f'*, to be reversed, if desired, without affecting the oil-separating capacity of the apparatus. To prevent back pressure, the aggregate area of the perforations of each baffle-plate exceeds the area of the steam inlet, *f*.

ELECTRICALLY CONTROLLED OIL SWITCHES.

Figs. 17 and 18 show respectively a front and a rear view of a 15,000-volt electrically controlled oil circuit-breaker made by the Hartman Circuit Breaker Co., of Mansfield, Ohio. The panel containing the oil switch, operating solenoids and overload relays, can be installed at any convenient point in the station and operated from the

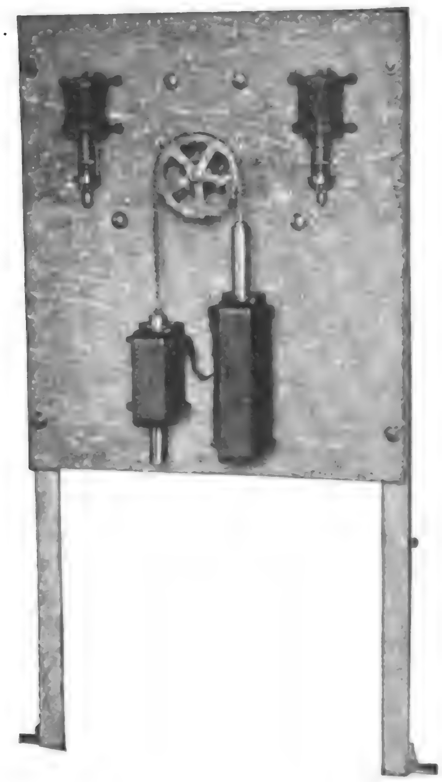

FIG. 17.—FRONT VIEW OF CIRCUIT-BREAKER.

main switchboard by means of a small double-throw switch. The rotary movement used in opening and closing the Hartman switch readily lends itself to solenoid control. The usual operating handle is replaced by a steel sprocket wheel. The link belt which engages the sprocket wheel is attached at one end to the movable core of the closing solenoid and at the other end to the core of the opening solenoid. The downward movement of the core of the larger solenoid effects the closing of the switch and the same movement of the core of the smaller solenoid effects the opening of the switch. The small double-throw switch for operating the indicating lamps on the main switchboard is located on the operating shaft back of the sprocket wheel. The operating current is derived from the exciters, a storage battery or any convenient source of direct-

current supply. The solenoids can be wound for any standard voltage. When an automatic switch is required the overload relays are placed on the same panel, and the operation of the plunger of either relay will close the direct-current circuit and effect the opening of the circuit-breaker. A combined overload and inverse time limit relay is shown in Fig. 17. The time limit operates on the vacuum principle, the admission of a smaller or greater quantity of air into the brass tube containing the plunger having the effect of retarding or accelerating the movement of the latter. On an ordinary overload the automatic opening of the circuit-breaker may be delayed for any desired period up

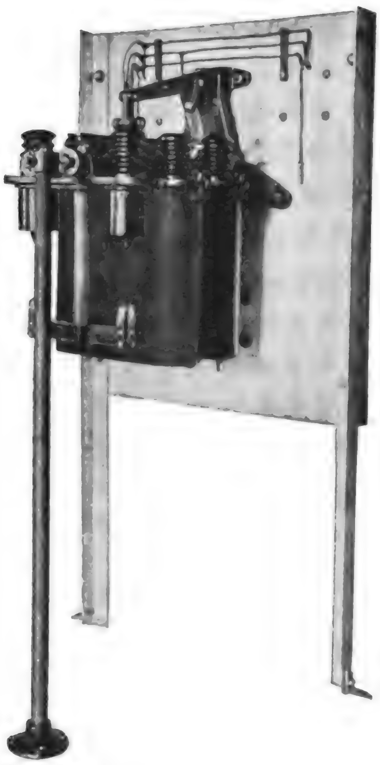

FIG. 18.—REAR VIEW OF CIRCUIT-BREAKER.

to 10 seconds. The heavier the overload, however, the quicker will be the action of the plunger, and an excessive overload or short circuit will cause the plunger to act almost instantly. The switch shown in Fig. 18 is a three-pole standard, type C switch, which is made for potentials up to 22,000 volts. The live parts of each pole are enclosed in a cell made of specially treated indurated fibre. The contacts are of the laminated, double-break type and the oil tanks are moulded in such a way as to isolate each breaking point.

DOUBLE-ENDED HORIZONTAL WATER-TUBE BOILER.

Fig. 19 shows the double-ended water-tube boiler built by the Parker Boiler Company, of Philadelphia, Pa. The drums are constructed in accordance with the very latest practice, using the best material and riveting of the highest efficiency. The diaphragm of ¼-in. steel plate is riveted to the shell and arranged to form a pocket at the front to collect the scale discharged from the tubes. The anti-priming valve is hinged to the diaphragm head and serves as a manhole for the lower chamber. The bottom of the drum below the level of the nipples leading to the elements forms the sediment pan or mud drum. An inverted angle with closed ends is placed along the bottom of the drum and over the blow-off opening, making the blow-off effective for its full length. The tubes are expanded into the junction boxes, which are like return bends, holding two tubes. This arrangement permits the free expansion of every tube without strain on any joint. The flexibility of the construction is such that the boxes can be separated several inches at any point for admittance to the baffles or for renewing a tube, giving sufficient opening to permit the removal of evaporating elements are two tubes wide, passing the water twice across the furnace at each level. The connection to the drum at the upper or induction end is made by an expanded tube entering an "inlet" box which supplies two elements, each having a brass non-return valve in the top junction box, and the lower end of each element is connected to the steam chamber by an independent upcast. The baffles to direct the course of the gases are made up of small fire tiles resting on the tubes. The illustration shows a 700 h.p. boiler fired at both ends with inclined stokers and equipped with a superheater. The working pressure is 200 lbs. The lower tubes are inclined to give space for the superheater,

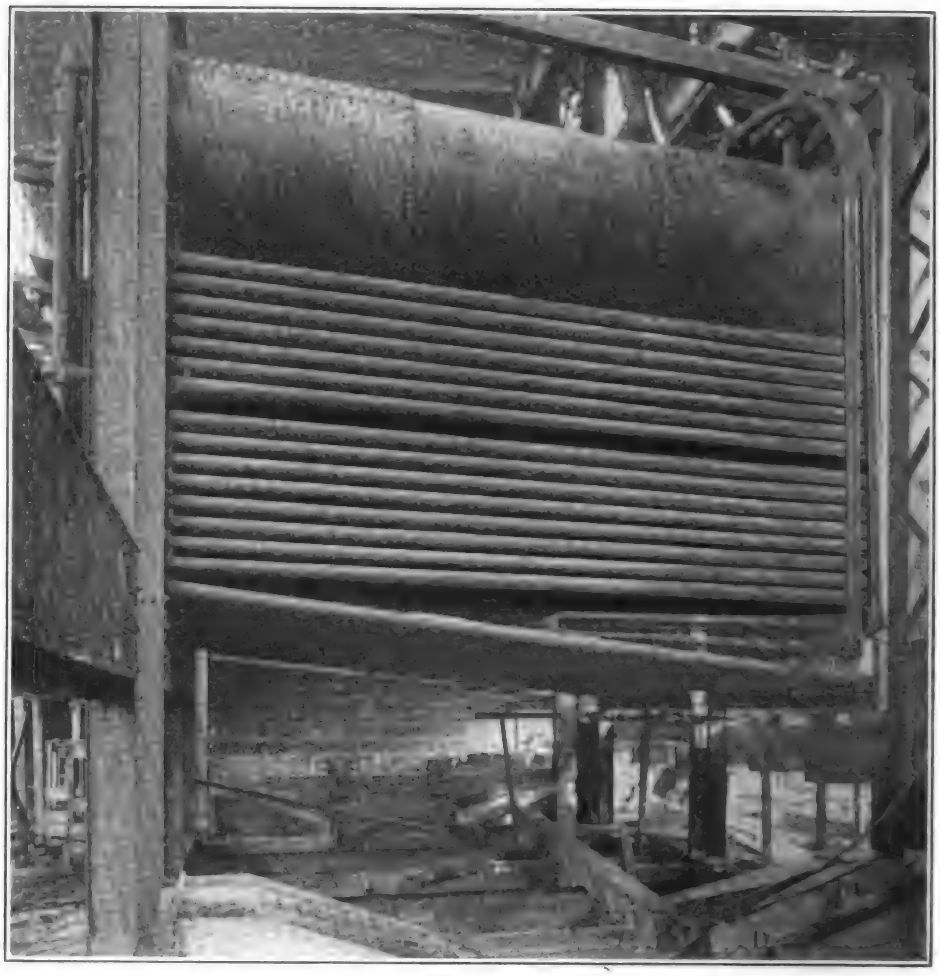

FIG. 19.—PARKER WATER-TUBE BOILER WITH SUPERHEATER.

18-ft. tubes in a 10-ft. fire room. Each tube is accessible for removal. In high boilers, the lower row of tubes is usually inclined, giving access to the baffles and lower tubes without lifting the boxes. The tubes above the top baffle form the feed element. The inlet end is connected to the drum with an expanded nipple, and the feed connection is made to the top rear junction box beyond the non-return valve. The flow in the element is forward and back alternately through each tube in the top row, then down to the next row, and so on, finally discharging through a vertical upcast into the rear drumhead above the diaphragm. A blow-off connection is made at the bottom end of the feed element, and water can be forced through the entire element under full boiler pressure. The lower or and as much heat can be passed direct to the superheater as desired. The heating surface is as follows: Economizer surface, 3,000 sq. ft.; evaporating surface, 4,000 sq. ft.; superheating surface, 375 sq. ft. The grate surface is 140 sq. ft. The boiler proper, without the economizer and with a single grate is rated at 400 h.p., but by doubling the grate surface it has been run up to 940 h.p. The addition of the economizer keeps the flue gases down to about 400°, and makes the economy very high for that rate of working. Aside from the economy in space obtained, the advantages claimed for this boiler are as follows: The scale can be removed from the tubes automatically while the boiler is in operation; the flexible construction permits the independent expansion of every tube; the combination of boiler

and economizer in one setting, with the downward course of the water and steam in the tubes, increases the efficiency of the heating surface by bringing the coolest water next to the coolest gases; the strong non-reversible flow make burnt tubes impossible, as distinguished from the uncertain circulation in inclined tubes; the inside circular hand-hole covers, held to their seats by the pressure, with conical ground joints, require no cleaning nor packing, and do not become leaky; and the separate chambers for steam and for water, with anti-priming valve between, make wet steam impossible.

THE "LOEW" CLOSED FEED-WATER HEATER.

It is a well-known fact that when water is heated in a tube, the center is not heated as rapidly as the outer surface of the water. Bearing this fact in mind the Loew Supply & Manufacturing Company, of Cleveland, Ohio, has designed the feed-water heater shown by Fig. 20 herewith, so that when water traveling through the tubes reaches the several ports at the top and bottom of the various sections the course of the water is changed, the water thoroughly mixed and the temperature thus equalized. The heater is also arranged to pass the water six times through the exhaust. Ample space for expansion after heating is allowed, so that friction from this cause is minimized. The cold water entering the water inlet is carried up to a double port at the top of the heater where its course is changed and the water mixed. It then passes down the second section of tubes through a cored passage to the port at the bottom where the same change is effected; the water passing through the third section, etc., to the final double port and down through the sixth section to the outlet. The heater is built of cast iron with straight seamless brass tubes. The top tube plate is free to move so as to allow for the expansion of the tubes when hot. A hand-hole is provided at the bottom of the heater for cleaning purposes, and when an open surface of the tubes for cleaning purposes is desired the top heads may be easily removed and the bottom unbolted and dropped down.

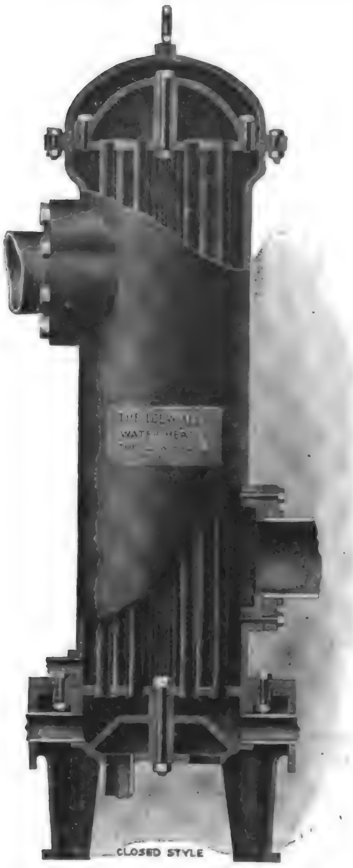

FIG. 20.—FEED-WATER HEATER.

ANNUAL MEETING OF WESTINGHOUSE MANAGERS.

The annual convention of the district managers of the Westinghouse Electric & Manufacturing Company was held November 13-16, at the general offices of the company at East Pittsburg. Mr. R. L. Warner, New England manager of the company, acted as chairman of the meetings, which were attended by the following representatives of the company: C. S. Powell, general agent, New York City; W. F. Zimmerman, representative, New York City; Maurice Coster, manager export department, New York City; W. C. Webster, assistant to second vice-president, New York City; F. H. Shepard, New York City; G. Pantaleoni, general southwestern manager, St. Louis, Mo.; J. R. Gordon, manager, Atlanta; H. H. Seabrook, manager, Baltimore; D. E. Manson, manager, Boston; C. W. Underwood, manager, Buffalo; T. P. Gaylord, manager, Chicago; C. W. Regester, manager, Cincinnati; G. B. Dusinberre, manager, Cleveland; J. E. Johnson, manager, Dallas; L. M. Cargo, manager, Denver; C. F. Medbury, manager, Detroit; T. J. McGill, manager, Minneapolis; C. A. Bragg, manager, Philadelphia; W. F. Fowler, manager, Pittsburg; D. E. Webster, manager, St. Louis; W. W. Briggs, manager, San Francisco; M. P. Randolph, manager, Seattle; Paul T. Brady, manager, Syracuse.

GROUP OF DISTRICT MANAGERS OF THE WESTIN GHOUSE ELECTRIC & MANUFACTURING CO.

At the opening session, which was held Monday morning, addresses were delivered by Mr. E. M. Herr, first vice-president of the company; by Mr. Frank H. Taylor, second vice-president, and by other officials. During the four days of the convention papers on topics of general interest were read by many of the officials and managers and by representatives of allied companies. On Wednesday evening the delegates and representatives of the local Westinghouse companies were entertained at the Hotel Schenley by Mr. Herr.

OBITUARY.

MR. BEAUCHAMP H. SMITH, second vice-president of the S. Morgan Smith Company, of York, Pa., died at his home in Los Angeles, Cal., on November 1, at the age of 36 years. Mr. Smith went to Los Angeles about five years ago for the benefit of his health and has since resided there in the hopes of a complete and permanent recovery.

MR. CHARLES CUTTRISS, inventor of the Cuttriss syphon recorder and head of the electrical department of the Commercial Cable Company, shot himself in his home in New York City on November 18, during a fit of temporary dementia caused by poor health. Mr. Cuttriss was a native of Bedford, England, and at the time of his death was 56 years of age. He is survived by a widow and three children. He graduated from Glasgow University, where he was a student and protege of Lord Kelvin, of whose submarine cable apparatus he made a special study for years. For twenty-one years, Mr. Cuttriss has been in the employ of the Commercial Cable Company and had traveled in the interests of the company almost everywhere the company's wires lead. He was a member of the American Institute of Electrical Engineers, the British Institute of Electrical Engineers and the New York Electrical Society.

PERSONAL.

MR. ROBERT F. McDOBLE, consulting engineer, of San Francisco, has severed his connection with the Abner Doble Company, in order to resume his individual practice.

MR. I. E. STOREY, the electric motor designer and inventor, has removed to Madison, Wis., in order to carry out to better advantage his work with the Northern Electrical Manufacturing Company.

MR. CLOYD MARSHALL has resigned his position as engineer of the Union Electric Light & Power Company, of St. Louis, and has become connected with the American De Forest Wireless Telegraph Company at St. Louis.

MR. CHARLES C. REMSEN, of the Sprague Electric Company, and Miss Mary Edna Fiske, were married in St. Paul's Methodist Episcopal Church, Newark, N. J., Nov. 1. Mr. and Mrs. Remsen went south on their wedding trip.

MR. CHARLES W. DODGE, who for the past ten years has been interested in engineering in New England, has entered the employ of Dodge & Day, of Philadelphia, and is at present giving his entire attention to extensive alterations and additions to the plant of the Link Belt Machinery Company, Chicago, Ill.

MR. V. C. GILPIN has opened offices at 120 Liberty Street, where he will represent the Tower-Burford knife switches and panel boards, the Monarch special lamps and "Arc Burst," and the Acme refilled incandescent lamps. Mr. Gilpin is widely known not only in the electrical supply trade of New York, but throughout the country.

MR. E. V. ENSIGN, after eleven years of continuous service as superintendent of the Leominster (Mass.) Electric Light & Power Company, has handed in his resignation to take effect in the near future. He will be succeeded by Mr. A. N. Clarke, of Boston, a practical business man, who is said to be well qualified to take charge of the plant.

MR. ALFRED E. BRADDELL, the well-known electrical engineer and electrical inspector of the Underwriters' Association of the Middle Department, Philadelphia, has resigned that position, and on December 1 joins the conduit department of the Sprague Electric Company in New York City. Mr. Braddell has a large circle of acquaintances in metropolitan and other electrical circles.

MR. J. B. DILLON, traffic manager of the Western Union office at Louisville, Ky., has been offered the position of chief operator for the company at Memphis, Tenn., and entered upon his new duties November 15. Mr. Dillon has been with the Louisville office for several years, starting as check boy and working his way up to his recent position of traffic manager. He has the reputation of being a fine operator and an expert electrician.

MR. H. D. ENDERISS has become associated with Mr. Louis J. Costa, 1229 Real Estate Trust Building, Philadelphia, Pa., and they will together represent the various firms whose interests in Pennsylvania and surrounding States have heretofore been looked after by Mr. Costa alone. Among the concerns represented by Messrs. Costa & Enderiss are the Jandus Company, the Chase-Shawmut Company and the Keystone Electrical Instrument Company.

MR. R. M. VAN VLEET, until recently associated with the Pittsburg office of the Cutler-Hammer Manufacturing Company, has been made manager of that company's Chicago office. Prior to his connection with the Cutler-Hammer Company, Mr. Van Vleet was electrical superintendent of the Columbia Iron Works, Port Huron, Mich., and his many years of practical experience in the electrical field have qualified him to efficiently look after the interests of his company in his new field.

MR. C. W. KELLOGG, who has had charge of the Brockton plant of the Edison Electric Illuminating Company, succeeding Mr. Preston Player, who was promoted fifteen months ago to the Blue Hill station, has been notified that Stone & Webster propose to transfer him to their plant in El Paso, Texas. There he will have charge of the station which furnishes light for the city and power for the trolley lines. Mr. A. F. Nelson will succeed him in immediate charge, and it is said that the Brockton and Lowell plants will be combined under the district management of Mr. N. T. Wilcox, of the latter city.

MR. A. P. PECK, who is well known in the Middle West as a successful salesman of electrical machinery, has joined the Allis-Chalmers Company and will hereafter be connected with the New York office of that company. He will travel throughout the New York district, giving particular attention to the sale of power and electrical machinery. Mr. Peck is an associate member of the American Institute of Electrical Engineers. He is a native of Chicago and was graduated from Purdue University, becoming identified immediately with the electrical engineering department of the Chicago World's Fair as assistant engineer of arc lighting. Since then he has represented successively the Westinghouse Electric & Manufacturing Company, the New York Belting & Packing Company, the Chicago Edison Company and the National Electric Company.

TRADE PUBLICATIONS.

POLYPHASE INDUCTION MOTORS. National Electric Company, Milwaukee, Wis.—Bulletin No. 359, describing the 25 and 60-cyle induction motors built by the company.

STEAM ENGINES. The Westinghouse Machine Company, East Pittsburg, Pa.—Catalogue W. M. 7004, describing in full the Westinghouse "Standard" engine. The general make-up of the catalogue is exceptionally good.

ELEVATORS.—A handsomely executed catalogue of standard size issued by the Otis Elevator Company of New York, illustrating and describing, in general, elevating machinery and apparatus manufactured by the company.

ELECTRICAL MEASURING INSTRUMENTS. The Simplex Company, Newark, N. J.—A pocket-size advance catalgue illustrating the complete line of portable and switchboard measuring instruments for both direct and alternating current circuits.

TOOLS. Brown & Sharpe Manufacturing Company, Providence, R. I.—A new edition of the company's Machinist's Tool Catalogue, devoted to tools too numerous to mention. The entirely new products of the company are enumerated on a colored insert.

TELEPHONES. Stromberg-Carlson Telephone Manufacturing Company, Rochester, N. Y., and Chicago, Ill. — A pocket-size booklet telling briefly some of the advantages of a private telephone system and illustrating a few of the different styles of telephones built by the company.

HOISTING ENGINES.—C. W. Hunt Company, West New Brighton, N. Y.—Catalogue No. 058, devoted to "Hunt" steam hoisting engines. The engines described in the catalogue are unusually massive in construction, and especially designed for heavy duty in continuous service.

BELT - DRIVEN, DIRECT - CURRENT MACHINERY. Crocker - Wheeler Company, Ampere, N. J.—Bulletin No. 61, superseding Bulletin No. 46, devoted to Form D, belt-type, direct-current machines, the motors ranging in size from 10 to 275 horse-power and the dynamos from 9 to 225 kilowatts.

MECHANICAL DRAFT. B. F. Sturtevant Company, Hyde Park, Mass.—Pocket-size Bulletin No. 75, entitled "Mechanical Draft. What It is. What It Does." The difference between forced and induced draft is pointed out and illustrations are given of plants using both, the Sturtevant system of mechanical draft, of course, being used.

MEASURING INSTRUMENTS. Keystone Electrical Instrument Company, Philadelphia, Pa. —Publication No. XIII, illustrating and describing Keystone standard reading instruments for direct-current circuits in switchboard and portable types. These latter include voltmeters, ammeters, milli-volt and am-meters, ohmmeters, and volt-ammeters.

GRINDERS. Stow Manufacturing Company, Binghamton, N. Y.—A circular descriptive of the new heavy stationary or portable emery grinder, electrically driven, brought out by the company. Multi-speed is obtained through the Stow motor, which, as is well known, requires no controller or rheostat, speed variation being secured by changing the magnetic reluctance of the field.

STEAM TURBINES. General Electric Company.—A well-illustrated catalogue showing some representative installations of Curtis steam turbines which are briefly described in the titles. The first machine was placed in commercial service October 1, 1902. Curtis turbines now in daily commercial service have a rated capacity of over 135,000 kilowatts and an overload capacity of over 202,300 kilowatts.

BELT PREPARATIONS. Cling-Surface Company, Buffalo, N. Y.—A special publication entitled "The Effect of Preparations Applied to Belts," giving the results of some interesting tests made with various belt preparations at Cornell University. The comparative values of the various belt preparations on the market when tested under the same working conditions are given. The booklet is a decided addition to belting literature.

BUSINESS NEWS.

AMERICAN ELECTRICAL HEATER COMPANY, Detroit, Mich., has moved its New York offices from 35 Dey Street to 7 and 9 Warren Street.

O. S. WHITLOCK & CO., West Orange, N. J., have recently removed their factory from Newark to the above address, where they have a larger factory and much better facilities for handling their growing business.

AMERICAN ELECTRIC SIGN COMPANY, Boston, Mass., has removed from 133 Summer Street to larger quarters at 44 High Street, where it will have much better facilities for handling its increasing business.

THE LEE ELECTRIC LIGHT COMPANY Clarinda, Ia., contemplates entering the ice making and cold storage field, in connection with its electric light and power business, and would be pleased to receive catalogues and price lists from dealers in this class of machinery.

THE O. C. WHITE COMPANY, Worcester, Mass., suffered from a fire recently, which threatened the destruction of the entire property. The stock was badly damaged by smoke, water and chemicals, but the machinery and tools were all saved, though also somewhat damaged. The company, however, effected temporary repairs immediately and has been shipping orders as usual.

FORT WAYNE ELECTRIC WORKS, Fort Wayne, Ind., has moved its Boston office, under the management of Mr. J. Allan Smith, from 518 Exchange Building into more commodious quarters at 110 State Street, rooms 601-604 Plymouth Building. The old telephone number, Main 2044, is still retained. This change was necessitated by the large increase in busines transacted by this office.

THE LAGONDA MANUFACTURING COMPANY, Springfield, Ohio, announces that it has purchased two acres of ground, upon which will be constructed at once a cement block and steel plant. The building will be 200 feet long, 50 feet wide, and it is hoped to have it completed this fall. The company's present plant is quite inadequate, though it is now being run night and day to meet the demands of the trade.

DENISON MANUFACTURING COMPANY, Warren, Ohio, is bringing out a student's electric engine, which is said to run at variable speeds, either way, from 200 to 3000 r.p.m. Both speed and reverse can be changed by means of a controlling lever while the engine is in motion. The engine can be operated by either one or two dry batteries and will develop power enough to run small toys, belts, pulleys, etc.

G. M. GEST, the expert subway contractor of New York and Cincinnati, has been awarded the contract for the construction of a complete subway system at Chattanooga, Tenn., for the East Tennessee Bell Telephone Company. Active work on construction has been commenced and is to be rushed to speedy conclusion. This is the first conduit work installed in the city of Chattanooga, and the system will be a large one.

CHANDLER & TAYLOR COMPANY, Indianapolis, Ind., reports among recent contracts the following: Three engines for the Michigan Agricultural College at Lansing, Mich., of standard service enclosed self-oiling type for direct connection to Bullock generators; an engine of the same type for the N. Auth Provision Company, Washington, D. C.; three engines, one of 100 kilowatts and two of 50 kilowatts capacity, to the Sisters of Providence Charitable Institution, St. Marys, Ind.

PITTSBURG GAGE & SUPPLY COMPANY, Pittsburg, Pa., reports a material increase from month to month in the sales of White Star oil filters. Among rcent purchasers of this company's product may be mentioned: Wabash Clay Company, Veedersburg, Ind.; Lalance & Grosjean Manufacturing Company, Harrisburg, Pa.; Campbell & Wright, Tuskegee, Ala.; Gilmore & Davis Company, Tallahassee, Fla.; Driggs-Seabury Ordinance Corporation, Sharon, Pa., and the Schmulbach Brewing Company, Wheeling, W. Va.

ELECTRICAL TESTING LABORATORIES, New York City, in response to the demands of its clients, has installed a machine for testing some of the mechanical properties of conductors. The rated capacity of this machine, in the measurement of tensile strength, is 15,000 pounds, which is sufficient to break a No. 0000 hard-drawn copper wire. By this addition to its equipment the company now has excellent facilities for all such tests of wires and cables as are ordinarily required in electrical practice. These comprise measurements of conductivity, insulation resistance, dielectric strength, electrostatic capacity, tensile strength, elongation, elastic limit, etc.

KEYSTONE ELECTRICAL INSTRUMENT COMPANY, Philadelphia, Pa., announces that it has established agencies for the sale of its instruments, as follows: 170 Summer Street, Boston, in care of F. B. Smith; 114 Liberty Street, New York City, in charge of Arthur Organ; 1229 Real Estate Trust Building, Philadelphia, managed by Louis J. Costa; 1526 Park Building, Pittsburg, under the management of J. L. Merrill; 165 S. Canal Street, Chicago, which will be looked after by Wm. P. Crockett; Seventh and Hickory Streets, St. Louis, where the company will be represented by the St. Louis Electric Manufacturing Company.

AUTOMATIC ELECTRIC COMPANY, Chicago, Ill., is in receipt of a letter from the secretary of the Citizens' Telephone Company, Grand Rapids, Mich., which is a very satisfactory testimonial to the success of the company's automatic telephones. The telephone company reports a net gain of 829 telephones since January 1, 1905. A few weeks ago the exchange had 6,784 instruments in service, and it is expected to reach the 7,000 mark before the holidays. The automatic apparatus was installed January 9, 1904, displacing a manual telephone exchange with 5,094 telephones, leaving a net gain of 1,629 in approximately twenty months, despite an increase in rates.

AMERICAN BLOWER COMPANY, Detroit, Mich., is erecting a three-story addition to its plant. This is made necessary by the rapidly increasing business of the company, which is said to be partly due to the growing demand for its Type "A" enclosed vertical, self-oiling engine, which was placed on the market some two or three years ago. The building will be of steel and brick construction. The first floor will be devoted to the erection and testing of engines, for which the best facilities will be provided; the second floor will be used for storing engine parts and painting the completed engines, and the third floor will be utilized for storage purposes entirely.

THE HOLTZER-CABOT ELECTRIC COMPANY announces that it has decided to discontinue its New York offices after December 1. The company has been led to take this step, believing it to be in the interests of its patrons to deal direct with the head office; since the nature of its business involving, as it does, such a variety of engineering problems, makes direct dealing desirable if not essential. The management feels confident that this change will enable it to handle the business more expeditiously than in the past, and therefore to the greater satisfaction of its trade. All communications in the future should be addressed to The Holtzer-Cabot Company, Brookline, Mass.

ALLIS-CHALMERS COMPANY, Milwaukee, Wis., has been awarded contracts for a vertical triple-expansion crank and fly wheel pumping engine, with a daily capacity of 6,000,000 U. S. gallons against a head of 190 feet, by the Newport water works, Newport, R. I.; for a horizontal compound condensing engine, having a capacity of 1,500,000 U. S. gallons in 24 hours against a head of 290 feet, by the Metropolitan Water & Sewerage Board, of Boston; three centrifugal pumps, each with a capacity of 10,000,000 gallons daily, for the Massapequa pumping station, Borough of Brooklyn water works; and for the complete electrical and power equipment for the new municipal lighting plant shortly to be installed by the City of Alpena, Mich.

THE STROMBERG-CARLSON TELEPHONE MANUFACTURING COMPANY, Rochester, N. Y., reports having closed contracts for switchboards for the following places: Friendly, W. Va.; Sistersville, W. Va.; New Matamoras, Ohio; Laclede, Mo.; Long Lake, Minn.; Eureka, Payson, Richmond and Tooele, Utah; Preston, Ida.; Lowville, N. Y.; Louisville, Ky.; Attica, Ind.; Rochester, N. Y.; Varna, Ill.; Varich, Mo.; Bouton and Atalissa, Ia.; Leonard, Mich.; Stuttgart Kan.; Stromsburg, Neb.; Stelhensport, Ky.; Yates City, Robinson and Lakewood, Ill.; Holt, Mo.; Houlton, Me.; Bingham, Tremonton and Carland, Utah; Columbus, O.; Robinson and Lakewood, Ill.; Chillicothe and Harrisonville, Mo.; Fulton, Kan.; Jamestown, N. Y.; Spanish Fork, Utah; Tonopah, Nev.

THE CHICAGO & NORTHWESTERN RAILWAY COMPANY has established an Industrial Bureau, the purpose of which is to furnish reliable information regarding the many desirable locations along the Northwestern Line for new manufacturing enterprises. Through the territory reached by this line, fine water-power locations abound that may be supplemented by electrical energy developed therefrom; vast forests of hard and soft timber for all kinds of wood-working concerns, mineral wealth that provides the material for foundry and machine work, and coal fields are close at hand. This feature should prove of much benefit, not only to the railway company, but also to the communities along the line, and such of them as have commercial organizations will find ready co-operation by this department.

THE UNDER-FEED STOKER COMPANY OF AMERICA, Chicago, Ill., calls attention to recent shipments of Jones stokers to various points throughout the United States and Canada. Among others are several in the electrical field, the largest of which are as follows: The Georgia Railways & Electric Company, of Atlanta, is about to equip 1584 horse-power of Babcock & Wilcox boilers with eight stokers, this being a duplicate of an order placed some months ago; another shipment is that of twelve stokers for the equipment of 1,800 horse-power of Wickes vertical water-tube boilers in the plant of the Bartlett Illuminating Company, Saginaw, Mich.; the Consolidated Light & Power Company, Pluma, S. Dak., has also contracted for the equipment of 1,400 horse-power of Babcock & Wilcox water-tube boilers requiring eight stokers.

DE LA VERGNE MACHINE COMPANY, New York City, has established a branch agency at Atlanta, Ga., in order to take care of its increasing business in the States of North Carolina, South Carolina, Alabama, Florida and Georgia. This agency will handle the business connected with the three lines of machinery manufactured by the company, namely, refrigerating and ice-making machinery, "Hornsby-Akroyd" oil engines and Koerting gas engines. Mr. W. M. Hargreaves will be in charge of the Atlanta office, which will be located at 510 Candler Building. The company also reports that in addition to completing its contract for 40,000 of Koerting two-cycle, double-acting gas engines, it has recently received a contract for three 500-hp Koerting gas engines to be direct-connected to 325-kw, 550-volt direct-current Crocker-Wheeler generators for the Boston Elevated Railway Company. These engines will be put in operation about January 1.

POWER IMPROVEMENT COMPANY, Milwaukee, Wis., on the first of November took over the agency relations and business of George P. Dravo, and will continue to look after the interests in the Northwest of the De Laval Steam Turbine Company and the Foster Superheater. Associated with Mr. Dravo will be Mr. Andrew Pinkerton, of the American Sheet & Tin Plate Company. Mr. Pinkerton is a member of the American Institute of Electrical Engineers, the American Electrochemical Society and the American Society of Mechanical Engineers. Having been actively engaged for fourteen years in the adaptation of electricity to power and lighting purposes and also to chemical work, he can intelligently advise as to its proper application. The Power Improvement Company therefore tenders its services in the capacity of counselor or contractor for the improvement and installation of electrical and mechanical power equipment in line with the work previously carried on by Mr. Dravo.

THE PEERLESS ELECTRIC COMPANY, Warren, Ohio, calls attention to its electrically driven laundry machinery. A recent development is a Peerless motor direct attached to an extractor, which a number of the foremost manufacturers of laundry machinery are prompt to adopt. New installations by this company are individual motor equipment for the planing mills of Wallace Bros., Mahoningtown, Pa.; the Lawrence Lumber Company, New Castle, Pa., and the Bagley & Sewel Company, Watertown, N. Y.; also individual motors for the Hayworth Publishing House, Washington, D. C.; fifteen motors for Eaton, Hurlburt Company, Pittsfield, Mass., and sixty-two motors for the new plant of the Sherman Envelope Company, Worcester, Mass. Peerless high-frequency

alternating-current generators for laboratory use have been ordered by Cornell University, and by Mr. Joseph Murgas, of Wilkesbarre, Pa. The State University of Iowa has placed orders for laboratory transformers and motors, and the Massachusetts Institute of Technology has given an additional order for Peerless machines.

WESTINGHOUSE ELECTRIC & MANUFACTURING COMPANY reports an increasing demand for its alternating-current motors of the "CCL" type. A number of grinders in paper mills have recently been equipped with Westinghouse alternating-current motors, and the operation of the grinders so driven has been so entirely satisfactory, it is said, as to leave no question concerning the practicability and efficiency of this drive. The Brooklyn Heights Railway Company has placed an order with the Westinghouse Company for a substantial addition to its present equipment, consisting of 300 No. 101-B Westinghouse direct-current railway motors and 150 sets of controllers, the order for motors being in addition to one placed some months ago for 600 machines of the same type. The company has just perfected a portable pipe thawing transformer of 5 kilowatts capacity, also a choke coil to work in connection with standard 15 to 20-kw lighting or power transformers, thus making standard capacity transformers available for thawing purposes in winter. A new line of Westinghouse ceiling and floor-column fan motors will be on the market the coming season, for both direct and alternating current. These fans will have four blades and ball bearings, and be finished in black enamel and oxidized copper. The alternating-current fans will be of the induction type and the direct-current fans will be furnished with three-point switches.

B. F. STURTEVANT COMPANY recently sold for export to Porto Rico a complete forced draft equipment for burning bagasse, the refuse sugar cane which is there extensively used for fuel. Among other large and important orders being filled by the company are several for complete heating and ventilating apparatus for numerous school buildings throughout the country, the Aetna Cotton Mills, Union, S. C.; shops of the Pennsylvania Railroad, the Detroit Oak Belting Company, Detroit, Mich.; the car and machine shops of H. S. Kerbaugh, Altoona, Pa., containing over three quarters of a million cubic feet of space; shops of the Page Woven Wire Fence Company; Ancram Paper Mills, Ancram, N. Y.; besides others for special induced draft equipment for the American Woolen Company, Maynard, Mass.; economizers for the Singer Manufacturing Company, Elizabethport, N. J.; Springville Manufacturing Company, Rockville, Conn., and the Nashua Manufacturing Company, Nashua, N. H.; air washing apparatus to be installed in connection with the heating and ventilating system in the office building of H. K. Porter Company, Pittsburg, Pa.; complete equipment for a modern smithshop, consisting of the forges, a pressure blower, exhaust fan and a system of smoke and blast piping; complete exhausting arrangement for the grinding wheels of the Imperial Cutlery Company, Avondale, N. J.; also mechanical draft apparatus for the Illinois Central Railroad Company, Chicago, Ill.; Cleveland-Cliffs Iron Company, Ishpeming, Mich.; Jefferson County Jail, Louisville, Ky.; Eaton, Cole & Burnham, Bridgeport, Conn., and the U. S. Custom House, New York City.

CENTRAL STATION NEWS

Readers are cordially invited to contribute to this department items of news relating to plants in their vicinity.

ALABAMA.

ABBEVILLE.—The citizens are discussing the question of constructing an electric light plant.

GUNTERSVILLE.—The question of constructing water works and an electric light plant is reported under consideration.

FORT PAYNE.—The Alabama Cooperage Company, of Fort Payne, has petitioned the Council for a franchise to construct an electric light plant to furnish light for the streets, residences and business houses.

MOBILE.—Mr. H. B. Rockwell, of New York City, for ten years connected with the New Hampshire Traction Company, has accepted the position of general superintendent of the Mobile Light & Railway Company.

ARIZONA.

PRESCOTT.—The McCabe Water, Light & Power Company has been incorporated with a capital stock of $50,000 by H. A. Suttle and Hiram E. Todd, both of Peoria, Ill.

ARKANSAS.

SHERIDAN.—E. C. Laine, of Pine Bluff, is about to put in an electric light plant here.

GRAVETTE.—G. W. Dunbar is interested in the construction of an electric light plant, street railway and water works.

HOT SPRINGS.—It is reported that the Citizens' Electric Light Company is about to be incorporated with a capital of $200,000.

NORTH LITTLE ROCK.—A water works and electric light plant will be constructed at North Little Rock. C. J. Humphreys, 104 East Fourth Street, a member of the Water Works Commission, has charge of the work.

CALIFORNIA.

SANTA ANA.—The City Trustees have decided to call a bond election for the purpose of deciding upon a bond issue of $135,000, of which $60,000 will be expended in the construction and equipment of a municipal electric light plant.

SAN FRANCISCO.—The Rubicon Water & Power Company has been incorporated by G. S. Wall, A. S. McDonald, R. A. Jackson, George C. Davis and H. D. Jerrett, with a capital stock of $1,000,000. San Francisco will be its principal place of business.

MOUNTAIN VIEW.—A committee consisting of W. A. Clark, D. B. Frink and O. Becker has been appointed by the Board of Trade to take preliminary steps looking to the establishment of a municipal light and power plant at this place. Power is at present supplied by the United Gas & Electric Company, of San Jose.

GILROY.—Engineer Thirber, of San Jose, who was employed by the City Council to furnish an estimate of the cost of an electric lighting plant, has submitted an estimate calling for $14,500. This is somewhat in excess of the funds available, but the council has decided to advertise for bids for the construction of the plant according to specifications and for the material needed for transmission lines.

RED BLUFF.—George W. Bush, of Redding, has filed claims on 18,000 miner's inches of water in Battle Creek below the mouth of Baldwin Creek for the purpose of generating electric power. Water is to be conducted in a canal 25 ft. wide and 6 ft. deep, and in wooden pipes 10 ft. in diameter, for a distance of six miles on the north side of Battle Creek to the vicinity of Horseshoe Bend.

LOS ANGELES.—The contract for the lighting of the public streets has been let by the council to the Los Angeles Gas & Electric Company for a term of three years. The cost will be $75.60 a year for each light. The same company is now supplying the city's lights at a cost of $6.75 a month for each light. During the next three years 300 lights will be added every year, which will make the total cost for lighting for the three years about $500,000.

CALISTOGA.—The Calistoga Electric Light & Power Company has filed articles of incorporation and proposes to establish an electric lighting and power plant that will supply all of its needs and those of the big wineries in this vicinity. The articles also provide for the establishment of a gas plant. The capital of the company is $20,000. The directors are G. W. Cutler, E. L. Armstrong and Mrs. Edna Brown, of Calistoga, and District Attorney Raymond Benjamin, of Napa.

OROVILLE.—The Oro Water, Light & Power Company has completed the contracts for the equipment of its electric transmission plant at Pentz by ordering two "double overhung" Pelton impulse wheel units. A 1000-h.p. wheel is placed at each end of a shaft, with a 1000-kw. General Electric three-phase railway-type generator in the middle. There are two of these units to be operated under a head of 465 ft., transmitting power 16 miles to Oroville, where city lighting and power for operating gold dredges will be supplied. There is an ample water supply from the Feather River Canyon.

RIO VISTA.—J. S. McDonald, representing the Rio Vista Electric Light & Power Company recently asked to be granted the privilege of erecting poles on the streets and a lease on certain town property on which he wishes to build a power plant. Mr. McDonald stated that it was desired to begin work at once so as to finish as soon as possible, before the rains delayed them too greatly. The town has already been staked out for the poles, and the grounds laid out for the power house. The plant will be large enough to supply a town twice the size of Rio Vista, and is valued in the neighborhood of $20,000. It has been in use in another part of the State for about eight months, so is comparatively new.

SAN FRANCISCO.—The Stanislaus Electric Power Company has been organized with a capital of $10,000,000. There has already been subscribed some $6,000,000. The financiers of the new incorporation are Tucker, Anthony & Co., of Boston, Mass., and the Knickerbocker Trust Company, of New York. Mr. B. Thompson, of San Francisco, was the organizer of the company, and Leopold Wallach, of New York, is understood to have interested Eastern capital in the enterprise. Both Mr. Wallach and Leopold Michels, president of the San Francisco Coke & Gas Company, are heavily interested in the new power company. The company has been organized to furnish San Francisco with electric power, and will probably be allied with the San Francisco Coke & Gas Company. It is understood that work has already been commenced on the middle fork of the Stanislaus River. The plans of the company call for 30,000 electrical horse-power, and in addition to that, water power equivalent to 20,000 horse-power. Two large storage reservoirs are to be built which will take in about 1,500 acres. Enough timber land is to be purchased to provide for the lumber necessary in the construction of flumes and buildings.

COLORADO.

COLORADO SPRINGS.—The Stevison Electric Company has been incorporated, with a capital of $5000, by W. F. Stevison, Maggie Stevison and F. A. Blakeley.

ROCKVALE.—The council of Rockvale has granted the Arkansas Valley Electric Light Company a 25-year franchise to construct and operate an electric light plant.

LAMAR.—State Auditor Bent was in Lamar recently, and while here placed an order for an entire new equipment for the Lamar Electric Company's power plant. The total improvements contracted for will cost $10,000.

BUENA VISTA.—The Buena Vista Electric Light Company has leased its plant to W. P. Eyre, who for a number of years has had the management of the plant. He has already begun remodeling the works, having installed a 125-h.p. Leffel water-wheel. The old incandescent lights used by the city are to be replaced with twenty-one enclosed arcs.

LAS ANIMAS.—D. Kennedy, general manager of the Las Animas Electric Company, has made the city an offer to relinquish municipal management of the water works system and turn the same over to his company, who will operate it at a rate of three and three-tenth cents per thousand gallons of water furnished. It is the intention to do the pumping with an electric motor. This is a material reduction over the present cost to the city, but in case of any considerable growth in the consumption of water, would not be so desirable. The electric company, however, proposes to enlarge its plant and furnish a day current to local industries.

CONNECTICUT.

RIDGEFIELD.—The plans for the plant of the Ridgefield Electric Light Company have been approved and contracts will soon be let for the work.

GUILFORD.—Preliminary operations have been inaugurated for an electric light circuit to Madison for which an independent power house will be erected in the near future, the location of which is not definitely decided upon.

HARTFORD.—The entire electrical system of the city is about to be changed over from direct to alternating current, and all the power will be supplied from the new station at Black Rock. The company has gradually been changing over the system until now only the central section of the city is operated from the steam station in Chestnut Street. When the entire system is changed it will mean the abandonment of the Chestnut Street power station as a source of supply.

NEW HAVEN.—The committee on public lighting adopted a resolution to be presented to the Board of Aldermen that the committee be instructed to confer with the United Illuminating Company, which has been furnishing the lights, and obtain terms for the renewal of the existing contract for electric arc street lights, expiring December 31. The resolution also instructed the committee to hold a public hearing in the matter and report for the consideration of the Board of Aldermen a draft of the contract between the city and the United Illuminating Company.

WINDSOR LOCKS.—Mr. Burdett Loomis, of Hartford, representing a syndicate of Philadelphia capitalists, has acquired a controlling interest in the capital stock of the Windsor Locks Electric Lighting Company, the price for the control being $200 a share. The company has a capital stock of $20,000, and it also has outstanding a $30,000 issue of 4½ per cent bonds, which mature in 1922. The company pays a regular dividend of 6 per cent, and it recently declared an extra of 4 per cent. It is expected that the new owners will expand the plant and operate it for power and light, both night and day. A gas plant will probably be added to the equipment at an early date.

CUBA.

HAVANA.—Mr. Edmund G. Vaughan, president of the National Bank of Havana, has been elected president of the Havana Electric & Gas Company.

DELAWARE.

DOVER.—The Metropolitan Gas & Electric Company, of Chicago, has been incorporated with a capital of $12,000,000, to furnish natural and artificial gas. The incorporators are Jos. Markley and Geo. F. Goodnow, of Chicago, and Harry W. Davis, of Wilmington, Del.

FLORIDA.

JACKSONVILLE.—The Allis-Chalmers Company, of Milwaukee, Wis., has secured the contract for two 500-kw. turbo-generators, with the necessary equipment, at $36,135.

GEORGIA.

TALLAPOOSA.—It was decided at a recent election, held for the purpose, to bond the town to the amount of $100,000 for the establishment of an electric light plant.

ROME.—R. L. West, of Atlanta, it is reported, is one of the promoters of a company which proposes constructing an electric plant on Etowah River, between Rome and Cartersville to furnish electricity to run machinery and for other purposes. The company has a capital of $400,000.

ATLANTA.—According to a quoted statement of Forest Adair, vice-president of the Atlanta Water & Electric Power Company, there can be no reopening of the question of the franchise of the company with the State, Mr. Adair claiming that the matter has been settled by arbitrators and that the proposed reopening of the matter by submission to another board is without precedent, as far as he knows. The state comptroller will, however, insist upon the collection of taxes on a valuation of nearly half a million dollars.

ATLANTA.—The Southern Light & Power Company has decided to issue $500,000 bonds, to be used for the construction of an electric plant in or near Atlanta, for the purpose of furnishing power in Fulton and DeKalb counties. The company has located the site of its building in Atlanta and has purchased the property upon which its offices will be erected. The building will be located on Edgewood Avenue, near the corner of Courtland Street. The property, which has a frontage of 85 feet on Edgewood Avenue and a depth of 85 feet, was purchased for $5,000 cash. General A. J. Warner, president of the North Georgia Electric Company, and also interested in the Southern Light & Power Company, states that the latter company was organized to furnish and distribute electric current for light and power in the city of Atlanta. It has contracted with the North Georgia Electric Company for electric current to be supplied continuously to any extent that may be required. The North Georgia Electric Company, and companies allied with it, now control water powers in the vicinity of Atlanta approximating 100,000 horse-power. Two powers on the upper Chattahoochee have already been developed and others are in process of development, and the power developed is ready for transmission to Atlanta as soon as the transmission line now being constructed is completed. The wires for this line will be carried on substantial steel towers instead of wooden poles.

ILLINOIS.

MONMOUTH.—The Monmouth Gas & Electric Company is reported to have completed plans for an electric light plant.

WATSEKA.—Foundations have been laid for an addition to the electric light plant, 25 x 75 feet. It will be a brick structure.

NASHVILLE.—K. H. Steinhauser has purchased the Nashville electric light plant from the present owners, the deal being closed at East St. Louis by C. M. Foreman.

PARIS.—The Paris Gas & Electric Company has been reorganized with Wm. Hunter, of Paris, as president, and J. C. Shumway, of Taylorville, secretary, and will issue $20,000 bonds to make improvements.

PANA.—The Pana City Council has granted the Pana Gas & Electric Company a franchise to lay pipes through the streets and alleys of the city. The city also closed a contract with the company to light the city at $72 a year for each lamp.

QUINCY.—The Quincy Gas, Electric & Heating Company, at its recent annual meeting, elected A. L. Stevens, of Detroit, Mich., president; J. T. Lynn, F. K. Pelton, M. G. Borgman, all of Detroit, respectively, vice-president, secretary and treasurer. The officers and Dr. J. H. Rock, of Detroit, and W. A. Bixby and Dr. J. H. Rice, of Quincy, were elected directors.

HOOPESTON.—The City Council has granted a fifty-year franchise to Mr. Charles J. Wakeman for a gas and electric lighting plant. It is proposed to rebuild the electric plant and to put in gas works. Mr. Wakeman is the president and manager of the present Hoopeston Electric Lighting & Heating Company, which has Westinghouse and Fort Wayne apparatus for lighting and a day power circuit.

STREATOR.—The People's Light & Railway Company and the Streator Gas & Light Company have been purchased and the two properties combined by the recently incorporated Illinois Light & Traction Company. The new corporation is capitalized at $400,000, and, in addition to extending the local lines will build an interurban road connecting Streator and Ottawa, Ill. Negotiations are pending, it is said, for the purchase of the street railway plants and the lighting plant at Ottawa.

INDIANA.

VINCENNES.—John Fries, Wm. Bolk and H. H. Osterhage are heading a company to build a large ice plant and cold-storage house. The company will also, it is understood, install an electric plant.

GENEVA.—W. R. Thurston has obtained a franchise to build a modern electric light plant here. Mr. Thurston has organized a stock company and proposes to have the plant in successful operation in a few months.

SHELBYVILLE.—The electric light plant of Shelbyville has been transferred to the Citizens' Water & Light Company by direction of the United States Court. A mortgage for $50,000 on the plant and property has been given to the United States Mortgage & Trust Company. The company is now proposing to make extensive improvements and install some modern machinery in the plant.

EVANSVILLE.—The Evansville Gas & Electric Light Company has entered into a contract to furnish electric power for three of the interurban roads running into Evansville, with a possibility of securing a similar contract for the fourth line. Extensive additions are being made to the company's plant in order to supply the needed power. The company estimates that it will expend upwards of $130,000 on these improvements.

TERRE HAUTE.—Municipal ownership of the electric light plants and other public utilities is the paramount issue in the campaign just closing in the cities of Terre Haute and Fort Wayne. Both political parties in each city are pledged to municipal ownership of such utilities, but differ widely as to the best method of bringing it about. The new cities and towns law of Indiana provides that such questions shall be submitted to a vote of the people.

INDIAN TERRITORY.

BROKEN ARROW.—A company is being organized to install an electric light plant here.

LEHIGH.—The Lehigh City Council has granted a franchise for electric lights and power to the Consumers' Ice Company, who will install the necessary plant at once.

FORT GIBSON.—A charter has been granted at Muskogee to the Fort Gibson Light & Traction Company, incorporated with a capital of $25,000. J. H. Nakdimo, of Fort Gibson, is president.

DAVIS.—W. P. Bullock is engineer in charge of the construction of an electric light and gas plant for J. B. Dickinson at this point. Mr. Dickinson has a 20-year franchise for furnishing electric lights and gas.

IOWA.

LE GRANDE.—The citizens have voted to establish a municipal lighting plant.

BURT.—The citizens of this city have voted for an electric light plant and a water works system.

INDEPENDENCE.—The city officials are said to be considering improving the water works and electric light plants.

ROCK RAPIDS.—Work on the new lighting plant is now being pushed and it is expected the plant will be completed very shortly.

KANSAS.

OSAWATOMIE.—W. H. Murphy has been granted a franchise to install an electric light plant here.

GALENA.—The Galena Electric, Gas & Power Company has been incorporated with a capital of $100,000.

GEARY.—The Geary Electric Light & Power Company has been incorporated with a capital of $5,000. Directors: Chas. F. Dyer, I. J. Robb and J. M. Robb, all of Bridgeport.

CHERRYVALE.—W. R. Morrow, proprietor of the electric light and power plant at Peru, is making preparations to install a plant here. He has a franchise from the city.

LA HARPE.—S. A. Gard, of Iola, has made a proposition here to the City Council to light the town. Wm. Turner, of this place, has also made a similar proposal. The plan of the latter is to operate the light plant in conjunction with the ice plant.

HUTCHINSON.—Two 500-kw. steam turbines will be furnished for the Water, Light & Gas Company by the Westinghouse Company. These will operate with dry saturated steam at the throttle of 10 pounds pressure and 28-inch vacuum. The 60-cycle generators will deliver two-phase current at 2,200 volts.

KENTUCKY.

MOREHEAD.—The City Council is reported to have granted J. E. Davidson a franchise to light the city.

OAKDALE.—The American Electric Lighting Company, a concern recently incorporated, has secured a contract from the board of trustees of Oakdale to furnish lights for that suburb for a term of five years.

NEWPORT.—The contract for public lighting at Newport will expire within a short time and the City Council is considering the matter of renewal. The Union Heat & Light Company has had the contract for some years.

PADUCAH.—Joseph L. Friedman has been chosen president of the Paducah Light & Power Company. This company was incorporated following the recent merger of the light and traction interests in Paducah, brought about by the sale of the street railway, gas and heating properties to Stone & Webster, and is capitalized at $450,000.

SPRINGFIELD.—The Springfield Water & Electric Light Company (Incorporated), contemplates enlarging its lighting plant. They now have two 100-h.p. boilers, one Chandler & Taylor automatic engine, and one 60-kw. Wiley generator belt-connected. For the new plant they want a 125 to 150-h.p. tubular boiler, a 100 or 125-kw. direct-connected generator, and a 125 to 150 h.p. direct-connected engine of good make. It is proposed to reinforce all the main lines and to build a new one in the city. They have now from the station four No. 0 wires to the central part of the city. Other small changes are contemplated. Mr. H. B. McElroy is the superintendent and manager of the company.

LOUISIANA.

WINFIELD.—J. T. M. Hancock, of Rustin, La., has secured the contract to put in an electric light system here.

ABBEVILLE.—The Town Council and water works committee of this city at a recent meeting informally discussed the water plans submitted and the advisability of acquiring or constructing an electric lighting plant in connection wtih the system.

MAINE.

DEXTER.—The Dexter Electric Light Company has passed into the control of N. Curtis Fletcher, of Boston. It is understood that the service will be extended and improved.

GREENVILLE.—The Greenville Light & Power Company is constructing a new and larger electric plant a short distance south of the outlet of Wilson pond, about three miles east of Greenville.

SANFORD.—Advices state that Mr. W. E. Davis, of this city, has been appointed electrical engineer of the Atlantic Shore Line Railway Company and also the Alfred Light & Power Company, succeeding in the former position C. E. Sawyer, resigned. Mr. Davis still retains his connection with the Sanford Mills.

BANGOR.—Two large water power projects are now interesting the people of Maine—one at Sanford, on the Mousam River, now well under way, and the other at Ellsworth, on Union River, soon to be undertaken. At Ellsworth, where most of the very considerable power afforded by the falls of Union River is now idle, owing to the decay of the lumber manufacturing industry there, a corporation known as the Bar Harbor & Union River Power Company proposes to build two dams, each about 700 feet in length and sixty feet high from base to crest, and developing each about 4,500 horse-power—the lower dam for power purposes only and the upper dam for storage and power. It is proposed to build the upper dam first, beginning in January next, with a crew of 300 men, with the expectation of completing the structure in one year. The lower dam will be completed within two years. The power to be developed will be for distribution over a wide area, including Bar Harbor and other places in Hancock County. The dam now in process of construction on Mousam River is to be 40 feet high and 800 feet long, and will cost about $100,000. It will contain about 15,000 cubic yards of masonry. About 600 acres will be covered to the depth of 18 feet by the back flow, making a fair-sized lake. The dam, which is to be completed January 1, 1906, is being built for the purpose of storing water for the power plant of the Atlantic Shore Line Railway Company. The company uses, with its present equipment, about 750 horse-power. The new dam will develop 3,000 horse-power, and the surplus, over the railway company's requirements, will be sold for manufacturing purposes. Loring M. Farnum & Company, of Boston, are the contractors.

MARYLAND.

HAGERSTOWN.—The receipts from the municipal electric light plant for September were $1,409.23, against $1,077.38 last year.

HAMILTON.—The Hamilton Water, Light & Power Company has been incorporated with a capital of $35,000, to supply water and light to Hamilton and Lauraville.

MASSACHUSETTS.

AMHERST.—The Amherst Gas & Electric Light Company will extend its service to West Pelham.

HAVERHILL.—The Haverhill Electric Company has petitioned the city to share the expense of placing its wires underground.

REVERE.—Mr. C. F. Chisholm has been appointed superintendent of the Suburban Gas & Electric Company, which has a large electric light plant here.

QUINCY.—A petition is reported to have been presented to the City Council, asking that the city take measures to secure by purchase a municipal gas or electric light pant.

PITTSFIELD.—The Great Barrington Power Company has awarded to the Stanley Company, of this city, the contract for generators and electrical equipment. The contract amounts to about $13,000.

WINCHESTER.—The Edison Electric Illuminating Company has lately taken over the business of lighting the streets and houses of Winchester, which service was formerly performed by the Woburn Light, Heat & Power Company.

FALL RIVER.—The Fall River Electric Light Company is reported to be preparing plans for a power station to be located on the easterly shore of Taunton River. Harry Bottomley, superintendent, Fall River.

FITCHBURG.—The committee on fuel and street lighting reported an agreement with Fitchburg Gas & Electric Light Company to furnish incandescent lights in all city buildings at 12 cents per kilowatt-hour, a cheaper rate than is now paid.

LEOMINSTER.—H. D. Jackson, of Boston, it is reported, has been engaged to superintend the improvements which the Massachusetts Lighting Company intends making to the plant of the Leominster Electric Light & Power Company, on Mechanic Street.

SALEM.—The street lighting contract expired the first of October, but as it contained a provision that it might be continued for six months without a new contract, there is no danger of the city being obliged to pay an extra price or going without lights before April 1, at least. The committee on street lighting is collecting data of what other places are paying for lights and the quality of the light, and proposes to place the whole matter before the City Council with the figures offered by the local company. There is a strong element in the Council in favor of returning to the open arc system, as it is claimed that the city was better lighted under that system and the apparent saving made by the change has been offset by the increased number of lights required.

MICHIGAN.

IRON RIVER.—The citizens have voted to issue $30,000 bonds for constructing an electric light plant and the rebuilding of the water works.

MORRICE.—The electric lighting plant owned by Sutton & McKay has been sold to John Hubert, of Lansing, and Edward Hubert, of Farmington.

LUDINGTON.—The County Board of Supervisors has granted to the Pere Marquette Light & Power Company a permit to erect a dam on the south branch of the Pere Marquette River in Mason County. J. H. Cotton is president of the company and George S. Root, vice-president. It is understood that the company intends to furnish power and light to Hart, Scottsville, Custer, Pentwater and other towns. It is said that a 30-foot fall can be secured with a very short dam.

DETROIT.—The Onaway Light & Power Company, which proposes to supply a number of towns in Cheboygan County, and has already a well-equipped plant in operation, at its recent annual meeting elected W. W. Vaughan, of West Branch, president; George J. Robinson, of the Onaway Banking Company, vice-president, and H. H. Vaughan, secretary and treasurer. The latter is also manager. The company has put out a bond issue of $25,000, with the Detroit Trust Company as trustee of the mortgage.

KALAMAZOO.—The Ceresco dam, being built by the Commonwealth Power Company, of this city, will be completed about December 15. Next to the dam at Allegan, owned by the same company, this dam will be the largest in the State, and will cost about $150,000. The power derived from it will supply several electric roads, as well as many cities and villages. The Commonwealth Company has contracted to furnish power to operate the Jackson & Lansing electric road. When this line is completed, it is stated that the company will furnish power for the Lansing & St. Johns and Lansing-Haslett Park lines, in addition to supplying manufacturers with power.

GRAND RAPIDS.—The Grand Rapids-Muskegon Electric Water Power Company has filed its acceptance of the franchise as amended recently by the Common Council of Muskegon. The amended franchise provides that a yearly franchise fee be paid the city and that consolidation with any other corporation makes the franchise void. Wires in certain streets must be placed underground. The contract has been let for the erection of a concrete power sub-station for the company. The building will be located at Muskegon Heights and will cost about $6,500. The company expects to deliver power in this city and Muskegon by February 1. The contract for a concrete sub-station here has been let.

GRAND RAPIDS.—The Cadillac Water & Light Company has been purchased by Grand Rapids and Cadillac investors and reorganized with a capitalization of $200,000. An authorized bond issue of $120,000 has also been arranged for. The bonds are to provide for the purchase and improvement of the property, which consists of the water and electric light plants in Cadillac, which have been in operation for a number of years under the ownership of W. W. Cummer. A meeting of the stockholders was held and these directors elected: L. H. Withey, Amos S. Musselman, Edward Fitzgerald, Claude Hamilton, Henry Sullivan, W. H. Gay and W. H. Anderson, Grand Rapids, and F. A. Diggins and Henry Knowlton, Cadillac. The officers are: William H. Anderson, president and treasurer; Edward Fitzgerald, vice-president, Grand Rapids; N. V. Gerrish, secretary, and George Westover, manager, Cadillac.

MINNESOTA.

ANNANDALE.—The Council, it is stated, is considering the construction of a lighting plant.

MINNESOTA CITY.—The Minnesota Light & Power Company is reported to be contemplating the enlargement of its plant.

MANKOTA.—The franchise of the Mankota & St. Peter Railway & Lighting Company has been extended to February 12, 1906. By that time the franchise of the Willard company also expires and one or the other will then be granted an extension.

NORTHFIELD.—The Northfield Light, Heat & Power Company has sold its plant to the Cannon Falls Electric Light Company, who will operate the plant by power transmitted from the dam to be built across Cannon River, one mile west of the falls.

MINNEAPOLIS.—At the special election held recently the proposition to issue $35,000 bonds for the building of a municipal lighting plant was

carried by a large vote. The result was 628 to 123. This means the city will build and operate its own plant instead of awarding the contract for lighting to a private company.

OWATONNA.—W. F. Wilford, in charge of the operating department of the Owatonna Gas, Electric & Heating Company, has been made local manager of the company to succeed W. A. Stanton, who resigned in order to devote his entire time to the management of the Owatonna exchange of the Northwestern Telephone Exchange Company.

DULUTH.—Work has been started on the new distributing plant for the Great Northern Power Company. The contract, amounting to $100,000, was recently awarded to J. W. Hilliard, and the structure is to be completed by next May. It will be five stories high, with a frontage of 72 feet on Fifteenth Avenue and 144 feet on Michigan and Superior Streets.

MINNEAPOLIS.—The Stillwater Gas & Electric Light Company held its annual meeting recently. E. L. Hospes was re-elected president; J. H. Brown, of Chicago, vice-president; J. G. W. Johnson, secretary and treasurer. The company decided to make a number of improvements next season, including the erection of a new building in which electricity will be generated when it is impossible to secure the desired current from the company's plant at Apple River. N. N. Johnson has resigned as superintendent of the company's plant.

MISSISSIPPI.

BYHALIA.—R. D. Berry is installing an electric light plant here.

STARKVILLE.—Bonds to the amount of $8,000 have been sold for extending the water and light plant.

SHUBUTA.—The Shubuta Light & Water Company has been incorporated with a capital of $5000 by B. Hutchins, A. Bond and others.

CLINTON.—A resolution has been adopted by the Mayor and Board of Aldermen, authorizing the issue of $2,000 bonds for the purpose of extending the electric light and water works systems.

MISSOURI.

ELDON.—N. E. Harvey has asked for a franchise for the putting in of an electric light plant here.

JOPLIN.—The Joplin Electric Light & Power Company has been incorporated with a capital of $75,000.

TRENTON.—The electric light company of this city is negotiating to furnish light to several of the neighboring towns.

PLEASANT HILL.—The Pleasant Hill Hotel, Light, Power & Water Company has been incorporated with a capital stock of $40,000.

BOWLING GREEN.—The Pike County Light & Power Company has been incorporated with a capital stock of $7,000. Noah H. Ledford is among the incorporators.

INDEPENDENCE.—The City Council is reported to have granted a franchise to the General Light, Heat & Power Company, subject to the approval of the citizens.

ST. LOUIS.—Mr. Cloyd Marshall has resigned his position as engineer in the power department of the Union Electric Light & Power Company, and become connected with the American De Forest Wireless Telegraph Company here.

ST. LOUIS.—The written acceptance of the General Service & Development Company of the terms imposed in its franchise, granted by the county court, has been filed at Clayton. This company owns an electric plant at Brentwood, and recently purchased the electric plant and contracts of the West St. Louis Water & Light Company, which is supplying a part of St. Louis County.

MONTANA.

HELENA.—Mr. C. E. A. Carr has been appointed manager of the Helena Light & Railway Company, succeeding Mr. Howard S. Reynolds, who returns to New York.

HELENA.—The Helena Power & Transmission Company has secured the right of way between Butte and Anaconda and the stringing of wires has begun. The company will furnish power for the concentrator at the Washoe smelter and indirectly to the street car company.

LIVINGSTON.—Two carloads of machinery for the new electric light plant have arrived. The power house is 50x100 feet in area. It is expected that the equipment will soon be installed and the plant ready for service.

HELENA.—The Wisconsin Bridge & Iron Company, of Milwaukee, Wis., has secured the contract to construct a steel dam near Helena, for the Missouri River Power Company. The dam will be 630 feet long, 70 feet high and capable of developing 10,000 horse-power.

DILLON.—The Dillon Electric Light & Power Company has begun the reconstruction of its entire system in this city. The steam plant is to be improved at a cost of $6,000 and the transmission line between the plant and the city, which now consists of No. 8 copper wire, is to be replaced by No. 4 copper wire. The total cost of the improvements is estimated at $10,000.

NEBRASKA.

ANTELOPE.—Work is being pushed along rapidly at the city's water and lighting plant.

BROKEN BOW.—This city is considering the establishment of an electric light plant.

LINCOLN.—The Chickasha Light, Heat & Power Company has been incorporated with a capital stock of $125,000.

YORK.—There is reported to be a movement here among the citizens looking to the construction of a municipal electric light plant.

FREMONT.—It is stated that it is proposed to install three new boilers and make other improvements at the municipal electric light plant.

FREMONT.—S. F. Stiles, city clerk, writes that about $5000 will be expended for improvements to the electric light plant. J. H. Mathews is superintendent.

FRIEND.—A number of citizens have secured a franchise and will install an electric light plant here.

AUBURN.—The Auburn City Council has entered into a contract with the Auburn Mutual Lighting & Power Company to light the streets, lanes and alleys of the city for a period of five years.

OMAHA.—The contract department of the Omaha Electric Light & Power Company announces that it has closed a contract with J. L. Brandeis & Sons to furnish light and power for their new store building. The contract is the largest ever closed by the company. It calls for approximately 400 arc and 7,000 incandescent lamps, and motors to operate the nine passenger and four freight elevators which will be installed in the building.

KEARNEY.—Col. F. W. Blees has disposed of his stock in the Northeastern Electric Heat & Power Company and retired from the business November 1. The new owners of the company are gentlemen who are largely interested in like enterprises in various places and are thoroughly experienced and have ample capital. The name of the company remains the same. William E. McCully, of Macon, Mo., is secretary, treasurer and general manager of the company. He will spend about half of his time in this city, notwithstanding his extensive interests elsewhere. He is secretary, treasurer and general manager of the following corporations: Macon Gas & Electric Light Company; Marshall (Mo.) Electric Light & Power Company; Palmyra (Mo.) Light & Water Company. The new president of the company is Thomas E. Wardell and the vice-president is Fred. H. Tedford. The resident manager will be S. J. Duncan. L. E. Watson, who has been manager of the plant under the ownership of Col. Blees has accepted the position of manager of the Beatrice (Neb.) electric plant.

NEVADA.

GARDNERVILLE.—A. C. Pratt has secured enough capital to carry out his electric power plant project on the Carson River.

RENO.—A movement is being made by the City Council toward the municipal ownership of the holdings of the Reno Power, Light & Water Company, and it is believed that some such deal will be consummated in the near future.

GOLDFIELD.—The California-Nevada Mining, Milling & Power Company is said to have secured all the water rights along the Pine Creek in Inyo County, Cal., and will erect an electric power plant near Alvord, Cal., from which point a transmission line will be constructed to the Bullfrog mining district at a cost of about $150,000.

RENO.—W. B. Arnett, a mining engineer of this city, has just taken up a valuable water appropriation for power purposes, his dam site being located one mile below Vista and six miles east of Reno on the Truckee River. Six years ago the same site was taken up by different parties, but Arnett claimed they had forfeited ownership by failure to develop it and the same view has been taken by the state engineer, Henry E. Thurtell, who granted Arnett's petition for an appropriation. He has secured all the water in the river at that place and says he has an average flow sufficient to generate 3,000 horse-power. Mr. Arnett has secured ample backing and next April will begin the erection of a $100,000 power and lighting plant with which to supply electricity to Reno and Sparks. He will begin work on the construction of a seven-mile ditch and flume at once.

NEW HAMPSHIRE.

NEWPORT.—The Sunapee Electric Light & Power Company, whcih is now operated by the Newport Electric Light Company, has just completed the work of rebuilding its lines. A 24-hour service will now be given.

NEWMARKET.—W. H. C. Follensby, of Exeter, has been appointed receiver of the Newmarket Electric Light, Heating & Power Company by Judge Stone. The appointment was in answer to the petition of the minority stockholders of the company, which alleged that the affairs of the company were being mismanaged by President J. W. Burnham, of Durham, who was the majority stockholder, and that the company was insolvent. Further, that $15,000 of the bonds of the company had been fraudulently issued by the president, and asking that W. E. Barrett, of Boston, president of the Union Trust Company, be asked to explain how he had come into possession of the bonds, which the latter did. Mr. Follensby has furnished $5,000 bonds.

NEW JERSEY.

PERTH AMBOY.—C. D. Boynton, secretary of the Citizens' Electric Light, Heat & Power Company, writes that it is proposed to construct an electric light and power plant.

NEWARK.—The Cape May electric light system is to be extended to Rio Grande, seven miles away, supplying light to the villages along the route.

PLEASANTVILLE.—A contract has been let for a 250-h.p. engine for the local electric light plant.

NEWTON.—The authorities of Newton have entered into a ten-year contract with the Newton Gas & Electric Company to furnish arc lights for $72.50 per lamp per year, and incandescents for $24.

NEWARK.—A special committee has reported to the Newark board of works that an electric light plant could be established at a cost of $125,000, which would light the streets at about one-half the present cost. The board of works has asked the City Council for an opinion on the city's right to build such a plant under present laws and will, if necessary, ask authorization from the State Legislature.

WASHINGTON.—A sale of the Washington Electric Light Company has just been effected by the Gas & Electric Development Company, of Philadelphia, which will also have charge of the extensive improvements to be made immediately and the future operation of the plant. The Washington company has always been a paying enterprise, but under the new management it is expected the earnings will be largely increased.

NEW MEXICO.

LAS VEGAS.—The contract has been let for a $150,000 power plant, to furnish this city and vicinity with power and light.

GALLUP.—The Gallup electric light plant, owned by Gregory Page, has been sold to E. C. Allen. The terms of the sale have not been made public,

but it is learned that the consideration is about $25,000. It is also said that the First National Bank is interested in the purchase. Mr. J. P. Mitchell has been appointed manager and superintendent of the plant under the new control.

NEW YORK.

BROCKPORT.—New arc lights are to be installed throughout the streets of the town.

BUFFALO.—At the recent election the citizens voted in favor of a municipal lighting plant.

MOORESVILLE.—The people have voted to issue bonds to the amount of $10,000 for the establishment of an electric light plant.

LYONS FALLS.—The village authorities have entered into a contract for a term of five years with G. H. P. Gould to furnish street lights.

WATERFORD.—The village trustees directed the light committee, president, attorney and engineer to ascertain the cost of constructing and operating an electric light plant.

MIDDLETOWN.—A majority of the stockholders of the Consumers' Light & Power Company voted to sell the company's plant to the Orange County Light & Power Company for $65,000.

NEW YORK.—The incorporation of the Hudson Electric Company is reported, with a capital of $5,000, and the following directors: E. W. Moore, F. H. Cowles and J. N. Shreve, New York.

LITTLE FALLS.—At an adjourned regular meeting of the Common Council recently held a franchise was granted to the Hudson River Electric Power Company to operate in this city for a term of 50 years.

MACEDON.—It is stated that the Town Board has granted a franchise to the Niagara & Lockport Power Company, to erect poles and wires for the transmission of heat, power and light along the highways of the town.

LOCKPORT.—Electric power from the Ontario Power Company's plant at Niagara Falls is now being received in this city. The gas and electric light company is utilizing the power, which is transmitted at 12,000 volts.

GOSHEN.—Goshen Illuminating Company has been incorporated to furnish gas and electricity. The company's capital is $25,000 and the incorporators are James Gamble and William H. Dixon, New York City, and John B. Johnston, Brooklyn.

BROOKLYN.—The Kings County Electric Light & Power Company of Brooklyn, it is reported, has applied to the State Gas & Electricity Commission at Albany for permission to increase its capital from $5,000,000 to $10,000,000 for the purpose of improving its plant.

LOCKPORT.—The Economy Light, Heat & Fuel Company, which recently obtained a 100-year franchise for light, heat, gas, power and refrigerator plants, will soon start work on its new electric light station. It is expected to have the plant in operation within six months.

POTSDAM.—A statement has been issued by the Hannawa Falls Power Company to the effect that the power company has secured the permission of all property owners along the route of the proposed power transmission line from Hannawa Falls to Ogdensburg, and that the pole line will soon be completed.

OSWEGO.—The Citizens' Lighting Company has been incorporated with a capital of $75,000 by J. C. Knight, Thomas Moore and C. A. Bentley, of Oswego. The outlook for the new lighting company is said to be more than encouraging. Contracts have been made with merchants and manufacturers embracing a period of three years and representing over $40,000.

UTICA.—The Utica Gas & Electric Company has entered into a contract with the Rome (N. Y.) Gas Company, whereby the former concern is to furnish electricity for lighting the city of Rome. A high-tension line will be built and power will be furnished from Trenton Falls to Rome, where it will be transformed to the proper voltage for the different requirements in that city.

WATKINS.—The Watkins Consolidated Gas & Electric Light Company, which went into the hands of a receiver last spring, has been reincorporated and will hereafter be known as the Watkins Illuminating & Power Company. The incorporators and chief stockholders are M. L. Driesbach, of Philadelphia, and M. H. Horn, of Jersey City. The capital stock has been fixed at $50,000.

AMSTERDAM.—Press reports state that the survey has been completed for the steel tower line between Amsterdam and Ballston, a distance of 20 miles, preliminary to the construction of work necessary to the bringing of Hudson River Electric Power Company's Spier Falls power to Utica. The survey for the balance of the line from Amsterdam to Utica will probably be started next week.

BROOKLYN.—Mr. Max Loewenthal, who of late years has devoted his attention and energies as an electrical engineer to the development of electric heating, has undertaken as a specialist the creation and development of a heating department for the Edison Electric Illuminating Company, of Brooklyn. Such an experiment is well worth the making for every local lighting company, and Mr. Loewenthal's work will be followed with deep interest.

ROCHESTER.—The stockholders of the Wayne County Electric Company, at their annual meeting, elected as directors: Charles D. Beebe, George Dunn, H. H. Crowell, Charles A. Lux, Dr. James W. Putnam, Dwight P. Chamberlain. The directors organized immediately after the stockholders' meeting, electing as officers: President, Dwight P. Chamberlain; vice-president, Charles A. Lux; secretary, Benton S. Rude; treasurer, William H. Akenhead.

LOCKPORT.—Work on the Buffalo transmission line of the Niagara, Lockport & Ontario Power Company has been begun. The line will run to Pendleton, then to Getzville, Williamsville and Buffalo. At a recent meeting of the stockholders the company elected the following board of directors: Harry H. Westinghouse, George C. Smith, Robert E. Drake, of Syracuse; Paul P. Brady, of New York; J. J. Albright, S. M. Clement, of Buffalo; Carl A. Degersdorff, of New York; William H. Gratwick, of Buffalo, and Edmund Hayes, of Buffalo. The last five take the place of I. H. Babcock, William Richmond, the Hon. Charles Hickey and William Higgs, of Lockport, and P. F. King, of Niagara Falls.

NEW YORK CITY.—New York City's first municipal electric light plant has been completed, and on October 30 was tested in the presence of a number of city officials. The current generated will be used to light the new Williamsburg bridge. By an investment of about $90,000 the city, it is expected, will make an annual saving of $12,000 in lighting the 124 arcs and 136 incandescent globes on the bridge. The plant was designed by H. de B. Parsons. There are two buildings, and the smokestack is 225 feet high. It is the first electric light works in the country to get its steam power as the result of the burning of garbage. The building which contains the furnaces and boilers is in charge of the street cleaning department, and the electric generating plant is under the bridge department.

OYSTER BAY.—After a fight that has lasted for years, the Nassau Electric Light & Power Company has absorbed the Oyster Bay Light & Power Company. Interested in the Nassau Company are Edwin D. Morgan, Clarence H. Mackay, Percy Chubb and other well-known men. The Oyster Bay company made a hard fight to keep the Nassau Company out of its territory, but at last had to succumb. The struggle between the rival companies was accompanied by many lively incidents. The Nassau people would start in to put up poles at night, but the local managers were always on the watch, and lawyers were sometimes routed out of bed at midnight to give an opinion as to the legality of the Nassau company's action. Men were sent out by the local company to chop down poles when it was thought they had been erected in violation of the law, and in some cases men employed by the Nassau company climbed to the tops of the objectionable poles and stayed there, defying their opponents to cut down the poles.

NORTH CAROLINA.

WILLIAMSON.—The town authorities want to correspond with electric companies relative to the installation of an electric light plant. S. J. Everett is secretary of the Business Men's Association.

LENOIR.—The Citizens' Light & Power Company has been incorporated with a capital of $25,000. The incorporators are H. F. Newland and W. B. Ivey. The company has been granted a 30-year exclusive franchise for an electric lighting and power plant, and will at once begin the installation of a 60-kw. single-phase lighting system, 60 cycles, 2,200 volts. The town has contracted for 21 arc lamps for five years.

ROANOKE RAPIDS.—Engineers are now preparing plans for the power house and electrical installation of the Roanoke Rapids Power Company. It is proposed to construct a dam across Roanoke River at this point, which for the first development will give the company about 9,500 horse-power. Later it is proposed to raise the dam so as to give about 25,000 horse-power for 11½ hours per day. C. P. E. Burgwyn, Richmond, Va., is the engineer in charge. H. C. Cooper, general manager, writes that the contract for the new power plant will probably not be let before spring.

SALISBURY.—The development of a large hydro-electric plant is being undertaken in Davidson County, five miles from Salisbury. D. Hartley, of Yadkin College, J. H. Swicegood, of Tyro Shops, and Prof. J. M. Bandy, of Greensboro, are among those who head the movement and have incorporated the Yadkin Development Company. The plan is to dig a canal 11 miles in length from a point on the Yadkin River at Yadkin College to a suitable location near Linwood, through which the current of the Yadkin River will be turned. The canal is to be 80 feet wide at the base and will average about 15 feet in depth. It is estimated by the engineers that not less than 30,000 to 35,000 horse-power will be available at one point when the canal shall have been completed.

NORTH DAKOTA.

LEEDS.—The Leeds Electric Light & Power Company will install a new electric light plant. A site for the plant has been secured and the construction work will be started immediately.

GRAND FORKS.—Edward A. Healy, of Red Lake Falls, has a plan to supply electric light for the city and was here recently talking over the venture to some local business men. His plan is to utilize the power of Thief River Falls to generate a current which if extended here will furnish cheap light.

OHIO.

ARLINGTON.—The electric light plant at Arlington burned recently. There was no insurance.

COLUMBUS.—The Lima Electric Railway & Light Company has increased its capital stock from $850,000 to $1,250,000.

FOREST.—At a special meeting of the Forest town council it was decided to advertise for bids for the erection of an electric lighting plant.

BELLEFONTAINE.—Appropriations have been made by the Bellefontaine council for a new municipal electric light plant to cost $50,000.

TOLEDO.—J. T. Ross became chief engineer of the Toledo Railways & Light Company on November 1. He is a well-known traction expert and engineer.

ASHTABULA.—The superintendent of the electric light plant has petitioned the finance committee for an appropriation of $7250 for improvements to the electric light plant.

PAINESVILLE.—The stockholders of the Commercial Electric Company held their annual meeting recently. The officers elected were T. E. Durban, president; W. N. Collister, vice-president, and W. E. Malin, secretary and treasurer.

CAREY.—Improvements have recently been made at the water works and lighting plant here, of which Harry C. Fink is manager and engineer. Two new Skinner engines have been installed, one of 150 horse-power and the other of 60 horse-power capacity; also a 100-kw. single-phase Wood generator.

JAMESTOWN.—Although the Jamestown Electric Light Company has been lighting the streets of Jamestown for ten years, it has just been granted a franchise. More lights will be used and a new contract made. It is said the town could have avoided paying light bills any time because of the lack of a franchise.

MANSFIELD.—The stockholders of the Mansfield Electric Light & Power Company have chosen directors. The following officers were elected by the board of directors: President, C. W. Upson; vice-president and treasurer, J. J. McIntyre; secretary and superintendent, W. C. Hedges.

CLEVELAND.—The people of Cleveland have voted in favor of giving the Bradley Electric Light & Power Company a franchise to furnish light, heat and power in Cleveland, in competition with the Cleveland Electric Illuminating Company. Whether the council will complete the grant to Mr. Bradley or not depends upon the attitude of the Legislature toward a home-rule law for Cleveland.

TOLEDO.—The Toledo Gas, Electric & Heating Company has about completed its lines in the downtown section of the city. The new turbine engine is in operation and is supplying current for the West End, while two additional 1,500-h.p. steam turbines have been ordered adapted for driving a direct-connected 60-cycle generator running at 1800 revolutions per minute and giving 7200 alternations per minute. They will be provided with secondary governor valves by means of which 50 per cent overload may be developed, or full load developed when operating with condenser. The generators will have four poles and will deliver three-phase current at 4400 to 4800 volts. The turbines will be of the Westinghouse make.

EAST LIVERPOOL.—Articles have been filed with the Secretary of State increasing the capital stock of the East Liverpool Traction & Light Company from $6000 to $3,000,000, as the result of a traction and light merger in southeastern Ohio. The deal includes the suspension bridge over the Ohio between East Liverpool and Chester, Pa., the East Liverpool & Rock Spring traction line, Rock Spring Park; the Chester Light & Power Company and the People's Light & Power Company. These properties will be merged with the electric lighting companies of East Liverpool and Wellsville. It is said that this move is a preliminary to a merger of all the electric lighting companies in eastern Ohio. Options have been taken on the Steubenville electric lines which extend to Toronto, and to Brilliant, and a gap is to be filled in between Toronto and Empire. Buffalo (N. Y.) capital is behind the movement.

OKLAHOMA TERRITORY.

LEHIGH.—The Consumers' Ice Company will install electric lights at Lehigh.

WOODWARD.—The Woodward Cotton Company has been granted a franchise to furnish the city with electric lights.

SHAWNEE.—Charles A. Freuauff, of New York, has bought the Shawnee Light & Power Company's plant and entire system, in Shawnee, for $108,000.

OREGON.

ASTORIA.—W. W. Whipple has secured a franchise to construct an electric light and gas plant and telephone system in Astoria.

SALEM.—The Calbe Cove Power Company, of Sumpter, has filed articles of incorporation, with $100,000 capital. O. C. Wright, T. C. Gray and E. Ray Jones are the incorporators.

ELGIN.—The Grand Ronde Power Company (Fred. Housch, engineer, La Grande, Ore.), is to extend its line to Elgin, and furnish light and power; probable cost of work, $20,000.

JUNCTION CITY.—The Gilmore Water Power Company has been incorporated here by S. P. Gilmore, Emma Gilmore and Eliza Gilmore for the purpose of establishing water works for irrigation and other purposes.

HAINES.—At a regular meeting of the Common Council held recently the application of J. F. O'Bryant to install and operate a power and light plant in the corporation limits for a period of thirty years was passed to its third reading and granted.

EUGENE.—W. T. Campbell and associates will, under the name of the Oregon Electric Power Company, appropriate water from Mackenzie River for the purpose of generating electric power. The power house will be located about eleven miles from Eugene. The company offers to furnish power for the proposed municipal electric light system.

EUGENE.—The City Council has employed Engineer Kelsey, of Salt Lake, Utah, to make surveys, plans and estimates for the proposed municipal electric light plant and water works, for which the citizens have voted to issue $200,000 bonds. The site for the power plant is reported to have been selected on McKenzie River, about thirty miles east of Eugene.

OREGON CITY.—H. W. Hageman, of Stone City, Ore., has completed financial arrangements for the construction of an electric light and power plant on Clackamas River, about seven miles above Oregon City. He will build a 35-ft. dam and construct a large power plant. It is proposed to furnish light and power to Park Place, Gladstone, Clackamas Heights, Oregon City and Portland.

BAKER CITY.—The Northwestern Gas & Electric Company, which practically controls all the gas and electric light plants from Boise to Walla Walla, will have an opposition fight in Baker City, as the Powder Valley Light & Power Company has petitioned the City Council for a franchise. The Powder Valley Company offers to pay the city three per cent of its gross earnings for the franchise, and, in addition, proposes a maximum scale of prices, which is very far below that now charged by the Baker City Gas & Electric Company, which is owned and controlled by I. P. Anderson, of the Northwestern Gas & Electric Company. The Powder Valley Company is erecting an immense plant on Powder River, and will string wires as far west as La Grande.

PORTLAND.—Machinery costing $165,000 for the Oregon Water Power & Railway Company is being delivered. The company is constructing a dam in the Clackamas River, at Cazadero, thirty-seven miles from Portland, and will install a plant to develop 20,000 horse-power. President W. H. Hurlburt officially announces that the plant will be completed and in operation before the end of next summer. The total cost will be $225,000. The Bullock Company, of Cincinnati, has the order for generators. The Stanley Company, of Pittsfield, Mass., is manufacturing the transformers. The water wheels come from the Pratt Iron Works, Dayton, Ohio. The power to be generated will be used in operating 100 miles of electric railway between Portland and Cazadero and branch lines in and about this city; also the electrically lighted pleasure park, "The Oaks." There will be a large surplus of power, and this will be delivered under a contract to the Portland General Electric, to be used in commercial lighting and power in this city.

PENNSYLVANIA.

LEBANON.—Geo. R. Hersey and Eli Nisley have secured an electric light franchise.

MALVERN.—Malvern Electric Light Company has been incorporated with a capital of $5000.

WEST CHESTER.—The Ridley Creek Supply Company has extended its line through Williston.

LEBANON.—The Edison Electric Illuminating Company will supply Myerstown and Avon with electric lights.

PLAINS.—Plains residents are considering the the formation of a company to furnish electric lights for this town and Miner's Mills.

FALCONER.—E. W. Jordan, of the Corry Electric Lighting Company, has secured a five-year contract to light the streets of Falconer.

YORK.—It is reported that the Conewingo Electric Power Company is about to construct a plant to furnish light to York, capable of supplying 30,000 horse-power.

HOMESTEAD.—Homestead business men have organized a light, heat and power company, which is to be capitalized at $100,000 and chartered to operate throughout Allegheny County.

MANHEIM.—Manheim borough has given a five-year contract for lighting the borough to the Manheim Electric Light & Heat Company at $11.50 per light per year. This is $2.50 per light less than the old contract, and will save the borough about $200 a year.

BENTON.—Definite steps have at last been taken towards bringing the Benton electric light plant into reality. The company has engaged W. O. De Witt of this town as consulting engineer, and he will at once prepare plans and specifications for the erection of the power house.

PHILADELPHIA.—S. L. Brumbaugh, general manager of the Juniata Hydro-Electric Company, writes in regard to the construction of the proposed electric plant on Juniata River, that the total cost of the work will be about $1,000,000. Bids for excavation steam shovel work, etc., will be received in about 30 days. Bids for electrical equipment will be received about January 1. Engineer, Wm. H. Cushman.

SOUTH CAROLINA.

EDGEFIELD.—It is proposed to install an electric light plant here.

BISHOPVILLE.—The corporators of the Bishopville Light & Power Company have secured a charter from the State of South Carolina.

BAMBERG.—It was voted on October 24 to issue $15,000 bonds for the construction of an electric light plant. The Board of Public Works will have charge of the construction.

SOUTH DAKOTA.

WILMOT.—A new electric light system is being installed at this place.

ABERDEEN.—F. W. Raymond, City Auditor, writes that the citizens voted November 9 to construct a municipal electric light plant.

SPEARFISH.—The Black Hills Traction Company is building a canal 5½ miles long, which will have a fall of 103 feet, and furnish from 1000 to 1200 horse-power. The dam to receive this water is almost completed. An electric light and power plant will be built to furnish power for mining companies and also for the trolley line which the Black Hills Traction Company intends to build from Spearfish to Deadwood and afterward to extend to various other points in the Black Hills.

TENNESSEE.

DAYTON.—C. F. Dowker, of Grandview, has purchased of Thomas E. Stone the city electric light plant and assumed charge immediately.

LAWRENCEBURG.—The citizens have voted to issue $25,000 bonds for the construction of water works and an electric light plant. Jas. Dunn, city secretary-treasurer, writes that no engineer has been employed as yet.

CHATTANOOGA.—A twenty-year exclusive franchise is for sale for a water and an electric light and power system, including rights of way, etc. For further information address I. L. Faucett, Chamberlain Building, Chattanooga.

MEMPHIS.—The Boardman Electric Company has filed an application for an amendment to its charter in order to change the name of the company to the Bluff City Electric Company. The incorporators are: H. H. Carson, R. M. Ellet, G. B. Thornton, Jr., and H. E. Hart.

KNOXVILLE.—The City Council, it is reported, has authorized the Board of Public Works to award to the Knoxville Railway & Light Company a contract for 303 or more arc lights at an annual cost of $72.50 per light per year, for a period of ten years, and to the Carbon Light & Power Company, a contract for 150 or more Welsbach gas lights of 62 candle-power each, at an annual cost of $21.50 each.

CHATTANOOGA.—We are informed that W. J. Oliver & Company, of Knoxville, Tenn., have secured the contract for the concrete work of the lock and dam power plant to be constructed at Hales Bar in Tennessee River by the Chattanooga-Tennessee River Power Company; contract price about $1,000,000. Additional contracts will be let in the near future for other work in connection with the above plant to include hydraulic and electric installation, structural work of power houses, transformers and transmission line. John Bogart, consulting engineer, 16 Exchange Place, New York, N. Y.; C. E. James, president, Chattanooga.

CHATTANOOGA.—Following the letting of the contract for the concrete work of the lake and dam for the power plant to be erected at Hale's Bar, in the Tennessee River, the Chattanooga & Tennessee River Power Company has

applied for an increase in the capital stock from $3,000,000 to $3,500,000. This is for the purpose of increasing the capacity of the power plant. According to the original plans the company was to erect a plant which would have a capacity of 36,000 horse-power. It is understood that this will now be increased to 50,000 horse-power.

TEXAS.

BEAUMONT.—R. C. Duff and others have applied for an electric light franchise here.

KILLEEN.—A local company has been organized for the purpose of installing an electric light plant at Killeen.

CLIFTON.—L. B. Thornton has sold his electric light plant and flouring mill to the Thornton Milling Company.

MARFA.—J. B. Covington, of Hearne, Texas, is going to put in both an electric light plant and telephone exchange in this place.

EAGLE PASS.—The Texas-Mexican Electric Light & Power Company has increased its capital stock from $40,000 to $80,000.

VAN BUREN.—A deed has been filed here transferring the Van Buren electric light and power plant to the Fort Smith-Van Buren Bridge & Traction Company.

MIDLOTHIAN.—The Midlothian Ice, Light & Water Company has been incorporated, with a capital of $20,000, by C. A. Moore, W. W. Meyer and others, all of Midlothian.

DUBLIN.—The Dublin Gas & Electric Company has been incorporated with a capital stock of $50,000 by J. F. Strickland, Oscar Godwin, of Dallas; M. B. Templeton, of Waxahachie; R. B. Sticher, of Sherman, and J. R. St. Clair, of Dublin.

WHITESBORO.—The council has granted a franchise to M. P. Kelly, of Gainesville, Texas, for the installation of a water works system. As soon as the installation is completed, Mr. Kelly will begin the construction of an electric light plant and sewerage system.

UTAH.

COALVILLE.—The City Council has awarded a contract to Thomas L. Allen for an electric power plant in this city.

SALT LAKE CITY.—Francis M. Lyman, Jr., has filed an application with the County Commissioners for a franchise to erect poles and string wires along the county highways. He owns water rights on Mill Creek and proposes constructing a power plant.

SALT LAKE CITY.—Malad Light & Power Company has been organized to succeed to the franchise, plant and rights of G. C. McLaughlin and Frank Moore in the town of Malad, Idaho. $100,000. C. F. Little, president; D. S. Taggart, vice-president; G. H. Jay, treasurer; J. A. Largent, secretary.

RICHFIELD.—A. J. Poulson has had his application for a large amount of water in the Sevier River for power purposes approved. He will form a company for the purpose of putting in a plant to utilize the power. It is purposed to build a plant to cost $60,000, three miles south of Elsinore, to develop electrical energy for Gold Mountain and for Richfield as well. The water power granted will develop 1000 horse-power.

RICHFIELD.—James Christensen, of Salt Lake, and H. N. Hayes, of Richfield, have become associated with Thomas and D. R. Brown, the original owners of the Richfield electric plant. The company has secured the upper water power rights above Glenwood. The company is incorporated under the title of the Richfield Light & Power Company and intends extending a line to Glenwood for the purpose of furnishing that town with light.

HEBER.—In addition to establishing an irrigation system to supply the settlers of Blue Bench on the Uintah reservation, the Blue Bench Co-operative Water Company (Irwin E. Pratt, secretary) also proposes furnishing electric light and power, and has filed application with the State Engineer at Salt Lake City for 200 second-feet of water from Rock Creek in Wasatch County, which it proposes developing and transmitting to Heber and elsewhere. The diverting canal will be 36,500 feet long.

VIRGINIA.

NORFOLK.—J. Edward Cole and W. D. Pender, representing separate interests, have each offered to install an independnt electric lighting and power plant in Norfolk if the retail merchants will subscribe to a certain amount of stock.

LYNCHBURG.—The new power house of the Lynchburg Traction & Light Company, on the James River, three miles above the city, has been put into service. The plant is to supply current for the street cars and for commercial lighting and power for factories. At present it has a capacity of 4500 horse-power, which can be largely increased. The plant is declared by experts to be one of the best in the South. It has been under construction for eighteen months and has cost upward of $150,000.

WASHINGTON.

BELLINGHAM.—The Bellingham City Council has ordered thirty-nine new arc lights for street lighting purposes.

OAKESDALE. — Mr. Shields, of Moscow, Idaho, is interested in the construction of an electric light plant at this place.

TENINO.—S. W. Fenton, it is reported, has applied to the County Commissioners at Olympia, for an electric light and water franchise for Tenino.

KENNEWICK.—C. F. Cochran and C. E. Wood, of Genesee, Idaho, have applied for a franchise for an electric light plant and water works here.

TACOMA.—The Sunnyside Council has entered into a lighting contract with the Prosser Falls Land & Power Company. The line will be built via Mabton.

WENATCHEE.—The Council, it is reported, is considering the question of purchasing the electric light plant of the Wenatchee Electric Power Company for $80,000.

GEORGETOWN.—The Seattle Electric Company has purchased within the last four months 18 acres of ground in Georgetown, on which it will build rolling stock, car barns and repair shops.

PALOUSE.—The Washington Water Power Company has begun work on its plant here, which will furnish power and light to Rockford, Fairfield, Latah, Tekoa, Farmington, Garfield, Colfax and Oakesdale.

BALLARD.—The entire plant and franchise of the Ballard Electric Company has been sold to the Seattle Electric Company, and it is stated that many improvements and additions will be made to the plant.

PORT ANGELES.—Mr. W. S. Hoskins, of Seattle, has made a proposition to take over the present electric light plant here, upon a twenty-year lease, for the purpose of superseding the city in the lighting business.

GARFIELD.—The city council of Garfield has granted a franchise to the Moscow (Idaho) Light & Power Company to light the city with electricity. Work on the line will begin January 1, 1906, and is to be completed July 1.

WEST SEATTLE.—A recent election resulted in the decision to issue $9000 bonds for the purpose of adding a lighting plant to the present municipal street railway plant. Specifications can be obtained from City Clerk W. G. Dickinson after January 1, 1906.

EVERETT.—The City Council has favored a motion made by Mr. Myers that the clerk be instructed to advertise for bids on the city lighting contract previous to the expiration of the present contract with the Everett Electric Company next March. The resolution provided that bids be submitted on contracts for five, seven and ten years.

DAYTON.—The Dayton Electric Company has been incorporated, capitalized at $75,000. Improvements are now in progress, aggregating $20,000. The old steam and water power plant will be replaced by a complete new hydraulic plant. The new barrel flume, 1500 feet long and fifty-five inches in diameter, will double the power of the old open flume and will enable steam power to be dispensed with. The new plant will run night and day, and during the day will furnish power for driving machinery in Dayton.

SNOQUALMIE FALLS.—The management of the Platt Iron Works Pacific Coast district agency has received reports of very successful tests of the new water wheel now in operation at the Seattle-Tacoma Power Company's plant at Snoqualmie Falls, Wash. The Type B. Victor turbine wheel direct-connected to a Westinghouse 5000-kw., three-phase generator tested at full gate developed 8000 kilowatts at the switchboard. This makes the capacity of the wheel 11,200 horse-power when operated at 300 r.p.m. under a head of 270 feet of water. This increase of capacity will be of much benefit to the company's service in the Puget Sound cities.

WALLA WALLA.—Secretary S. D. Sinkler, of the Northwestern Gas & Electric Company, has issued notices that there will be a meeting of stockholders at Walla Walla, December 21, for the purpose of voting on the proposition of increasing the capital stock of the company from $650,000 to $1,000,000 by the issuance of $350,000 8 per cent cumulative preferred stock, entitled to priority, both as to dividends and in the distribution of the assets upon dissolution of the company. The object of the increase in the capital stock is believed to be the building of another power plant on the upper Walla Walla River to provide for the rapidly increasing demands for power in Walla Walla, Pendleton, Athena and Weston.

WEST VIRGINIA.

PARKERSBURG.—The Acme Electric Company has secured its charter of incorporation, and at a recent meeting it was formally organized. The officers elected are: President and general manager, Henry M. Moses; vice-presidnt, Frank S. Mead; secretary, Richard K. Gibson; treasurer, Lewis P. Self; superintendent, Hugh J. Henry.

WISCONSIN.

MENASHA.—Menasha has voted to install an electric light plant.

RHINELANDER. — The Rhinelander Light Company has sold its wiring and supply branch of the business to C. A. Sutliff, of Grand Rapids, Mich. He will put in a full line of electrical goods.

MUKWONGO.—The Milwaukee Electric Railway & Light Company has come into possession of the mill property of John Hewitt. It is understood that the mill property will be used as a power house site.

FOND DU LAC.—T. F. Grover, who resigned recently as general manager of the Eastern Wisconsin Railway & Light Company, with headquarters in Fond du Lac, has moved to Chicago with his family and is now engaged in business in that city.

MILWAUKEE.—The Municipal Electric Light & Power Company, of this city, has been incorporated to supply electric light and power to the city of Milwaukee and its residents; capital, $100,000. Incorporators: L. S. Biron, J. A. Wallis and A. C. Moeller.

MILWAUKEE.—John I. Beggs, president and manager of the street railway company, says that unless the city enters into a contract for street lighting by the expiration of the present contract, December 15, the street lights will be turned off and the entire city will be in darkness.

LA CROSSE.—A combination of the electric lighting plants and electric railways in the vicinity of La Crosse is said to be in contemplation. The properties involved are announced as the La Crosse Railway Company, the Wisconsin Light & Power Company, the La Crosse Gas & Electric Company, and the proposed La Crosse & Black River Railway. It is purposed to transmit power from a large power plant on the Black River, near Black River Falls.

WYOMING.

LARAMIE.—The electric light difficulty in Laramie has been finally adjusted by the purchase of the old plant by the new company, known as the Laramie Light & Power Company, with a capital of $75,000, and represented by W. C. Sterne, of Littleton, Colo. The agreement to purchase the plant was reached at a meeting held at Littleton. The purchase price is to be the sum of $40,000 as a first mortgage on the plant. The new company contemplates extensive improvements, including the installation of an alternating current system.

NEW FUSELESS ROSETTES

Appreciated by all who have to do with wiring. May be fitted with cord and snapped on after the base is in position by merely a quarter turn of the wrist. Notice the stop in the cap. It can be put on only one way, so that in arc light work there is no possibility of reversing the current by taking off the rosette cap.

CAPS INTERCHANGEABLE.
FIT EITHER STYLE OF BASE.

Hole in cap takes new code cord. Sample sent prepaid.

That Happy Expression

denotes the absolute satisfaction which every

Penberthy Automatic Injector

gives to the user

For over 18 years the Penberthy has been known among the engineers of the country as the world's standard injector. No injector is allowed to leave the factory until it has been tested on actual boiler service, and proven its right to bear the Penberthy trade-mark, which is our guarantee of satisfaction. It combines reliability, durability and economy. Its simplicity of construction gives free access to parts and renders necessary repairs easy.

The Penberthy Force Feed Oil Pump

gives a positive easily regulated flow of oil, which can be adjusted to a drop. Its interchangeable ratchet drive wheels double its length of life. It works perfectly, regardless of speed of engine, and never wastes a drop of oil. Every engineer should know about it.

We manufacture a line of engine-room specialties that every engineer should know about. Our catalog gives full particulars. Write for it.

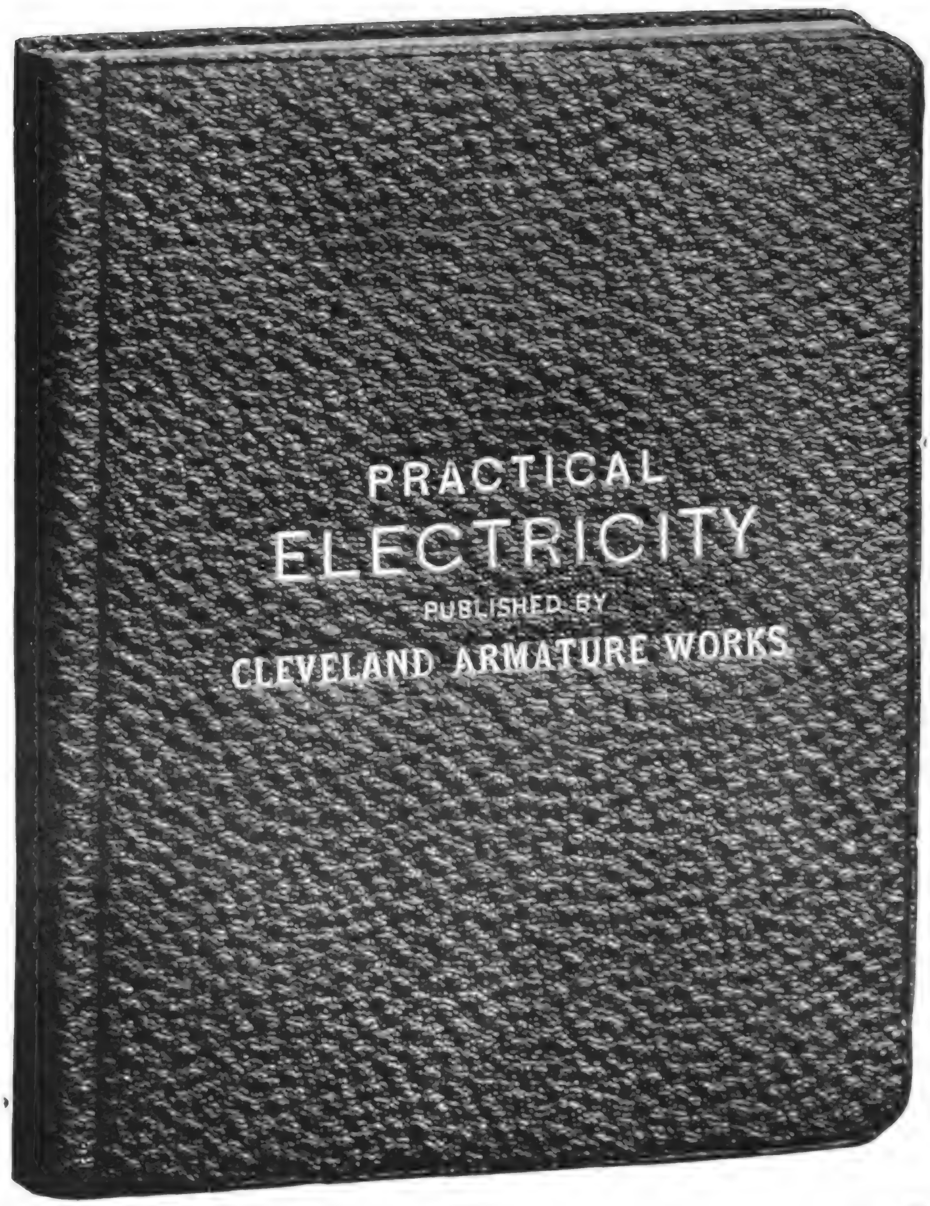
HOW ONE THING
LEADS TO
ANOTHER

From our paper, The Armature Winder, issued for the purpose of advertising our facilities for repairing electrical machinery, originated our book, Practical Electricity, which has proven to be the most popular book devoted to the study of electricity; 12,000 copies have found buyers, and the Fourth Edition is now ready. From Practical Electricity has sprung the manufacture of Dynamos and Motors.

By buying a copy of this book and becoming familiar with the art of electricity you don't know what it may lead up to.

There are XX chapters or subjects carrying you from the fundamental principles of electricity on through the various branches to a point where the careful student comprehends the complete designing, care and operation of a dynamo or motor. Each subject is carefully written and to the point. After a student studies a subject, he is questioned on that subject in such a manner as to bring clearly to his mind the points he needs to know regarding same. A DICTIONARY in back of book will enable him to learn the meaning of any electrical word, term or phrase used in this book as well as hundreds of others in common use. All required tables necessary in the study are in it.

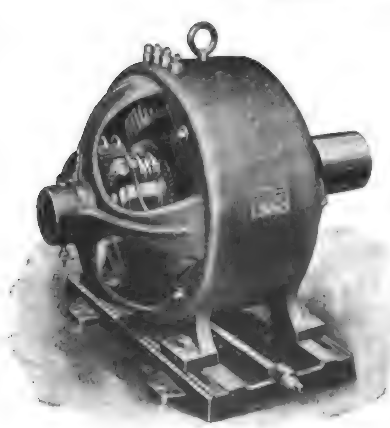


YOU CAN DO IT

While studying electricity from our book—and perfecting yourself in electrical engineering—you can be engaged in the sale of our dynamos and motors and earning a good commission.

Write for our catalogue and proposition in reference to how to sell, and commission we pay.

Our proposition is an ideal one for any man who is connected with a power plant or central station; the people to whom you furnish power will, in most cases, favor you if you but tell them you are agent for a good machine.



Price $2.00 per Copy.

This book will help you in the study of electricity as no other book ever has.

The offer we make of refunding Money if book is not satisfactory upon examination is AN UNUSUAL ONE in connection with the sale of a book. But we have no fear of its return. Your decision will be what thousands of others' have been. Money would not buy it if it could not be duplicated. We could print testimonials by the hundreds. It is the best to order and be your own judge of its merits.

WE OPERATE THE LARGEST REPAIR WORKS IN AMERICA. Let us quote you on winding your armatures, fields and refilling your commutators.

Announcement

We are now installed in our new three-story building at 336-338 Second Avenue, and are prepared to handle our customers' business in a very satisfactory manner.

Our rapidly increasing business has made necessary larger quarters, larger stock and increased shipping facilities.

We wish to thank our friends for their past patronage which has made this move necessary, and solicit a continuance of their favors.

E. E. S. C.

Everything Electrical

A complete stock of electrical supplies and Central Station material coupled with many excellent specialties gives us exceptional facilities for handling the business of our constantly increasing list of customers in a satisfactory manner.

Electrical Equipment & Supply Co.

Consulting Convenience and Economy

from the buyers' point of view, we have embodied in our products features that effect a saving in many ways:—By saving time, by increased durability, by reducing cost. Contractors and engineers who investigate, invariably specify BOSSERT GOODS.

Here are three of our products:

Drawn Steel Bushings

Indestructible and economical. Finished with enameled insulation, making them smoother than it is possible to make any cast iron bushings. Absolutely protect wires drawn over conduit ends.

Steel Drawn Wall Boxes

Save the cost of breakage and time used in making clean holes in cast iron boxes—a blow of the hammer knocks out the hermetically sealed plugs in our boxes, leaving a clean hole.

Bossert Knife Switches

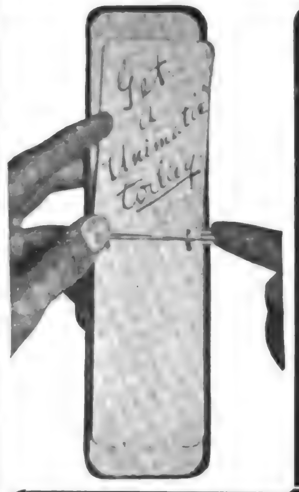
With multiple blades to each pole, increasing radiating surface, reducing tendency to heat. Adjustable bolts for taking up wear. No cast metal on conducting parts—pure drawn copper only.

Write for our catalog.

Bossert Electric Construction Co.

UTICA, N. Y., U. S. A.

AM. ELEC'N



BUSINESS—PROFESSIONAL MEN AND STUDENTS USE

FLAT-OPENING

LOOSE-LEAF BOOKS

FOR EVERY PURPOSE

They are more economical than bound books, and afford all the conveniences of all Loose-Leaf Systems

Write up your sheets on a typewriter
Classify your data in an up-to-date manner
Eliminate the dead matter as it accumulates

This will economize your time and afford you a satisfaction heretofore undreamed of.

THE "UNIMATIC"

(One Movement) and

THE "ROTAMATIC"

(Rotary Movement)

Constitute the most complete line of Flat-Opening Loose-Leaf Books in the world.

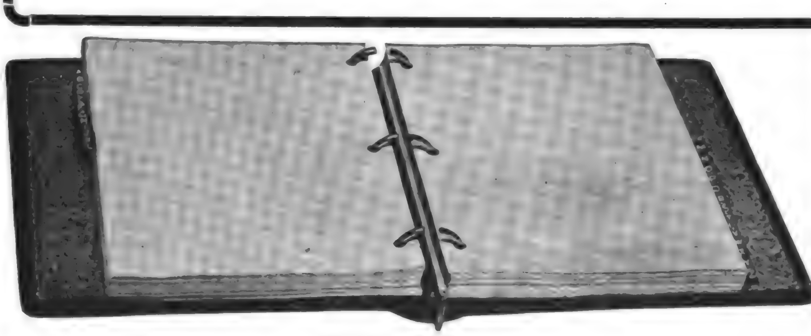
For the Vest Pocket—They provide the most condensed means of classifying an infinite variety of live matter for instant reference.

For the Coat Pocket—They furnish the best means of keeping up-to-date records of whatever subject are desired.

For the Desk—They have no equal for all kinds of business records.

Self-Indexing—Instant access to sheets for insertion or removal.

THE UNIMATIC



THE ROTAMATIC
A simple twist of the wrist opens or closes the arches.

Flat-Opening—No crimping of sheets required. Writing surface from edge to edge of sheet.

Compact, Convenient, Economical and Elegant. The best that money and brains can make.

ALL STATIONERS HAVE THEM

If not convenient to a dealer, write us for catalog.

Sieber & Trussell Manufactuing Company

82 DUANE STREET, NEW YORK

WAGNER

Electrical Instruments

for direct or alternating currents, possessing all the characteristic virtues of the best instruments on the market, with none of their faults. Prices place them within the reach of all. Voltmeters, Ammeters, Wattmeters and Power Factor Indicators.

Described in Bulletin 67.

1075

Transformers

for both lighting and power service, and equally satisfactory at either duty. Show practically the same regulation on unbalanced 3-wire load as on 2-wire load. Interchangeable on motor and lighting loads having same voltage ratio for both.

Described fully in Bulletin No. 65.

Single Phase Alternating Current Power Motors

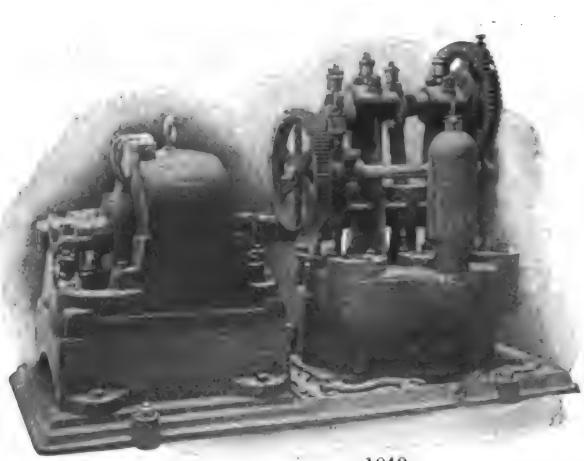
Require neither auxiliary condensers nor compensating transformer, and each is a complete unit within itself, possessing a starting torque characteristic, like that of the series direct current motor.

Described in Bulletin No. 68.

Direct Current Generators and Motors

Direct-current generators and motors, 125, 250 and 500 volts. Generators from ¾ K. W. to 50 K. W. Motors from 1 to 65 H.P.

Described in Bulletin No. 34.



1040

Motor Generators and Vehicle Charging Sets

We also manufacture a complete line of motor-generators for 60 and 133 cycles, A. C. to D. C. Vehicle charging outfits for 60 and 133 cycles, A. C. to D. C., as well as D. C. to D. C. The most satisfactory outfits in the market.

Described in Bulletin No. 69.

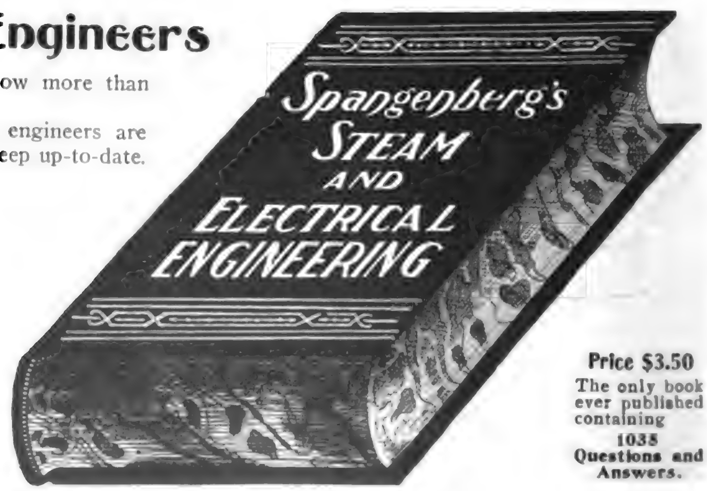
Good Times Ahead for Engineers

There's an ever increasing demand for engineers that know more than just enough to get a license.
The demand is for up-to-date engineers, and up-to-date engineers are those who keep right on studying—that's the only way to keep up-to-date.
A man like that can get more pay than you get now.
If you want more money, get more knowledge. Get it by reading

Spangenberg's Steam and Electrical Engineering
In Questions and Answers

A complete course in engineering, Stationary and Locomotive, Compressed Air Refrigeration, Gas and Gasoline Engines, Elevators, Repairs and Electrical Engineering.



Price $3.50
The only book ever published containing 1035 Questions and Answers.

NOTE MONTHLY PAYMENT PLAN

TO READERS OF AMERICAN ELECTRICIAN

In again asking the attention of the Mechanical World to the Hawkins' Engineers' Library and the "little at a time" payment plan on which these books are supplied, the publishers wish to express their appreciation of the hearty support and endorsement tendered by those who have been and continue to be students of engineering.

The Works are kept constantly "up to the times" by frequent revisions and additions by the author; to this fact is undoubtedly due their continued popularity.

$1 MONTHLY PAYMENTS

The books are sold on easy payments; the set, seven volumes, price $12.00, will be sent, express prepaid, to any address on receipt of $1.00, and agreement to pay balance in monthly instalments of $1.00. Each volume is complete in itself; one, two, three, four or five books of the series will be sent on the same easy terms, that is, one dollar with order and remainder of the purchase money $1.00 monthly.

CUT OUT AND MAIL TO-DAY

I accept your offer to supply me with HAWKINS' ENGINEERS' LIBRARY (seven volumes) for $12. Enclosed find $1 as first payment; the balance I promise to remit in $1 monthly instalments.

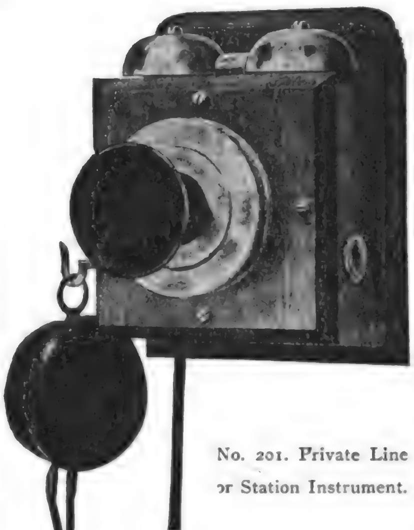
SAMSON JUNIOR GUARANTEED TELEPHONE SYSTEMS

These illustrations will, no doubt, be pleasing to you. We admit that our styles are good ones, but remember, we do not sell our instruments according to their outside appearance only. Their value, and what interests you the most, lies within the case.

"Our systems are installed in some of the largest hotels, apartment houses, and school houses in this country. We have also furnished complete telephone systems for the two largest steamers ever built in the United States. Could we not meet your requirement?



No. 201. Private Line or Station Instrument.

Our intercommunicating styles can be furnished in either flush metal or flush wood, which make exceptionally fine instruments for apartment houses, fine residences, etc.

Do you realize that a system can be supplied at a small expense?

Consider the advantages ducting your business with telephone service.

The expense is soon forgotten when satisfactory apparatus such as the Samson Junior Telephone is used.

ANNUNCIPHONE SWITCHBOARD

A moderately priced switchboard especially adapted for systems where intercommunication would be under the supervision of a clerk.

Instruments can be equipped with either our Single Contact, or metallic circuit jacks and with intercommunicating cord pairs, listening-in cams and supervisories.

Outside service equipment can also be furnished, as well as our celebrated Safeguard Fire Alarm Attachment.

Bulletins 1 and 6 explain fully.

No. 351 for Concealed Wiring.
No. 321 for Exposed Wiring.

Advise us what you desire to accomplish and we will inform you which system would be best adapted to your use and will send estimates.

No. 391 for Concealed Wiring.
No. 371 for Exposed Wiring.

No. 381 for Concealed Wiring.
No. 331 for Exposed Wiring.

EVERY ISSUE of the AMERICAN ELECTRICIAN is filled with important and timely articles reflecting the latest advances in both electrical and steam engineering and practice, the aim being to present matter of REAL intrinsic value to everyone interested in electricity and its applications.

Main Building, Armour Institute of Technology

THIS INSTITUTION WAS FOUNDED TO HELP MEN TO A TECHNICAL EDUCATION

You know whether or not you need a technical education.

You know that men who have attained success have had an education of some sort. And you know that a good many of these men have hewed out that education for themselves without going to College.

Every man doesn't have a chance to go to College.

But every man has a chance to make the best of his opportunities.

We can't give you a College education, but we can give you the next best thing to it.

We can help you to master many of the hard problems which stand in the way of your success, and we can help you lay a foundation of good, sound, common-sense information (genuine engineering knowledge) which every man must have if he is going to get ahead in his work.

Lincoln never went to College. Edison never had a technical education except what he gleaned from stray books. These men fought a hard battle and won.

And it was harder to get ahead then than it is now.

If you had an authority at your elbow, to consult with every day, at your work, think how fast you would learn and how quickly you would get ahead.

If you had a chance to ask all the questions you wanted to about your work:—how best to accomplish certain results; how to make quick repairs; how to "figure out" problems; how to make a drawing that would express that good idea you have thought of so long; how to save waste energy in the shop; how to save time and delays and the money that's thrown away every day in just this way—you would feel inclined to look into the matter, wouldn't you?

Well—that's just what we are offering you—an authority or a dozen authorities to consult on just these things.

You work under the personal direction of the members of the teaching staff of a great technical school—Armour Institute of Technology.

You can carry your class-room (your instruction paper) around in your pocket. You can read it at home, you can study it on the street car going to work, you can get a chance to look into it at noon-hour. And it wont be long before you will realize the benefits in your pay envelope. It wont be long before you may have a chance to be foreman, or superintendent, or start a small shop of your own.

The future is full of opportunities for the man who is ready for them.

You want to be that man.

The course you want may be any one of those listed below. What we have said applies to all of them. All we want is that you let us tell you more about what we can do for you. You can do it best by mailing us the coupon and checking the course you are interested in. DO IT NOW.

COUPON. Cut out out and mail to

AMERICAN SCHOOL OF CORRESPONDENCE

at Armour Institute of Technology **CHICAGO, ILL.**

Are You Tied Down

Are you tied down to work you do not like,—constantly dissatisfied—with little hopes of doing better? Do you intend to remain blindfolded all your life to good opportunities when they are offered to you?

If not, if you want to better yourself we will show you a simple and sure way, which we positively guarantee to be the right road to a better position and a good salary. All we ask of you is to write for our free 80-page book and testimonials from our students and convince yourself of our claims, and what we can do for you in your spare time.

Our system and our courses are the key to success. Courses in **Electrical Engineering, Steam Engineering, Mechanical Engineering, Telephony, Telegraphy, Electric Lighting, Electric Railways, Electric Motorman's Course, Short Electrical Course, Dynamo Tender's Course, Arithmetic, Algebra.** *Write to-day for our free book with testimonials. State subject which interests you.*

D. W. COOKE, General Passenger Agent, New York.

The test of years

has shown beyond a doubt that

Triumph Electrical Machinery

Triumph Motor, geared direct to Punching Press.

is unexcelled for efficiency, economy, and good wearing qualities.

Power and lighting service of the highest order is given by **Triumph Generators.** Built in both the belted and direct-connected types, these are designed in accordance with the latest principles of engineering practice, and are equipped with all modern improvements. The material and workmanship which enter into their construction are only of the best. To the excellence of their service, their many users will testify.

For practical results in operating machine tools, or, in fact, any sort of apparatus, the **Triumph Motor Drive** has achieved an enviable reputation. We make motors for all classes of work, and to meet any requirements.

We shall be pleased to answer your inquiries, and to send you our latestbulletins.

Ask for Bulletins "A 201 and 221."

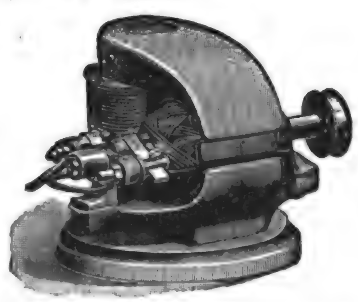
Price, $4.50.



Weight, 3¾ pounds. Will light 6-c.p. lamps, ring bells, explode powder. Output 10 to 20 watts. As a motor will develop 1-32 h.p. **Wound** for voltages 4 or 6, **as desired**. Other voltages up to 110 to order. Ask **your dealer** for illustrated **circulars** or send 2-cent stamp for them.

ELBRIDGE ELECTRICAL MANUFACTURING COMPANY,
Elbridge, N. Y., U. S. A.

THE INDUCTION MOTOR

Its Theory and Design, set forth by a Practical Method of Calculation.

By BOY DE LA TOUR.

TRANSLATED FROM THE FRENCH BY
C. O. MAILLOUX, M.A.I.E.E., M.I.E.E.,
Past President New York Electrical Society.

Cloth. About 250 pages, 75 diagrams. Price, $2.50.

This work is intended to elucidate the theory of the Induction Motor, and to facilitate its design by a practical method of calculation which is at once simple, ingenious and effective. The book will be useful to all who desire information regarding the peculiarities of the Induction Motor, especially those who desire to study the effect of changes or modifications in design and proportions on the performance of the Induction Motor and its adaptability to different purposes. The work will be especially valuable to the designer who is looking for relatively simple rules and methods, whereby the modifications in design and in details necessary to meet certain requirements may be predetermined.

Sent postage prepaid on receipt of price.

ENGBERG'S ELECTRICAL AND MECHANICAL WORKS
St. Joseph, Mich.

Noiseless Gearing For High Speed Motor Drives

NEW PROCESS PINIONS, meshed with accurately cut metal gears, will run at very high speeds, practically without noise. Being noiseless they increase the efficiency of workmen, it being recognized that noise distracts their attention, unsteadies their nerves, and decreases output.

NEW PROCESS PINIONS ARE NOISELESS

By reducing vibration NEW PROCESS PINIONS contribute to the long life of the machinery on which they are used. They are non-conductors of electricity and are ideal in every way for the motor drive.

NEW PROCESS PINIONS REDUCE VIBRATION

Our booklet is interesting and profitable reading for the mechanical man. Send for a copy.

Gas Engine Generating Units

THE UNITED STATES BATTERY COMPANY, NEW ROCHELLE, NEW YORK.

Pittsburg, Pa., June 21, 1904.

The Meriam-Abbott Co., Cleveland, Ohio.

Gentlemen:—We are pleased to advise you that the test made to-day on the Meriam-Abbott 16 Horse Power Gas Engine now installed at the Pittsburg Bible Institute, No. 12 Congress St., Pittsburg, showed full 16 horse-power for one hour, and an over-load of 20½ horse-power for some time without apparent strain and without reducing speed below the rate of 350 R. P. M.

This test showed this engine operating in a perfectly satisfactory manner.

Respectfully,
THE UNITED STATES BATTERY CO.,
D. H. Darling, Sec'y.

Investment or Expense?

You can buy electrical instruments at most any price. Look for cheapness and the cost is expense—expect no returns—expect added expense to keep the things fairly useful, expect constant undetected losses in your plant.

Pay a little more for quality—make quality your chief requirement—buy

Keystone Instruments

and the cost is an investment that will return your capital plus good interest. See catalogs 12 and 13.

At last my wants are well supplied,
Although I have the others tried;
Yet all good points for which I sought,
Were in that "SHAWMUT" Bushing, bought.

Uses

Shawmut

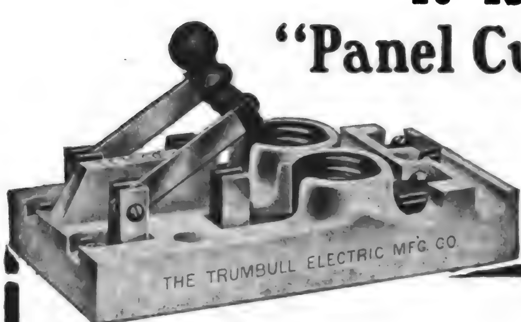
Outlet  **Bushings**

HAVE YOU TRIED THEM?

Then see Bulletin No. 31

CHASE-SHAWMUT CO.
NEWBURYPORT, MASS.

If it isn't a Trumbull it isn't a "Panel Cutout"



You can't carry panel boards in stock, because you can't tell just what you're going to need; but you can do better—you can carry a few Panel Cut-outs, and your wiremen can construct their panel boards at the very time they're needed.

When rough wiring, the wireman runs his branch circuits into the usual distributing box, and, when finishing up, puts in the necessary number of Panel Cut-outs.

Besides saving much time and trouble, Panel Cut-outs save on the first cost, for a distributing board can be constructed with them at one-third the cost of a slate panel board.

Order a few to-day, and see how much they'll save *you.*

VULCABESTON

THE TEST OF TIME

TIME REVEALS ALL THINGS

IT is TIME that brings out the flaws and imperfections that when young were carefully hidden by clever workmanship on the surface only.

It is the same TIME that VULCABESTON has so very successfully withstood and still stands.

It is the same TIME that has shown VULCABESTON in its true colors—the most efficient, durable, and reliable insulation ever manufactured.

VULCABESTON for years has STOOD THE TEST and proven its superiority over all other insulating materials.

VULCABESTON has very high insulating properties and great tensile strength.

It can be moulded into innumerable shapes suiting it for all conditions and requirements.

The C-H Rotary Press Controller

In the control of motor-driven rotary presses the two extremes of speed are demanded. Very slow speed for setting up the plates and threading in the paper, and "hurry up" speed to make up for delays in going to press.

In most control systems, to obtain slow speeds a second motor is necessary. With the Cutler-Hammer Rotary Press Controller but one motor is required for both the slowest and highest speeds, and it also provides for a large number of intermediate speeds. At any and every speed it gives a steady motion to the press, and prohibits its jumping, no matter how heavy it may be loaded.

This controller is so arranged that there is absolutely no arcing on the segments, the opening of the motor circuit being accomplished by the large solenoid shown in the cut. This solenoid is equipped with a carbon break and blow-out magnets for disrupting the arc. Protective devices are provided to quickly stop the press in case of accident.

Our Bulletin No. 65 tells about this type.

California

This Winter

The riches of health and the joys of a whole year are in a California winter.

California is not far away.

Fully two days nearer the Atlantic Coast than it was a few years ago. Correspondingly nearer from all Middle West points.

Plan your winter's trip NOW.

The cost of tickets is the SAME by all direct lines.

The service, scenery and accommodations are DIFFERENT.

On the Rock Island's Southern route, via El Paso, there are two fast through trains daily from Chicago and St. Louis.

It is the line of lowest altitudes and longest level stretches—the quickest route.

On the Rock Island's Scenic route, through Colorado and Salt Lake City, there are Standard and Tourist Pullmans through without change.

Write to-day for maps and booklets.

The Greatest Event in Electrical Journalism

On January 1, 1906, the *American Electrician* will be consolidated with the *Electrical World and Engineer*, the combined paper being thereafter known as the

ELECTRICAL WORLD

An outline of the plans for this consolidation, together with announcements of importance to advertisers and subscribers will be found on the following pages

McGRAW PUBLISHING COMPANY

The New
ELECTRICAL WORLD

Consolidation of "Electrical World and Engineer" and "American Electrician"

On January 1st, 1906, the Electrical World and Engineer and the American Electrician will be united and the consolidated journal will thereafter be known as the ELECTRICAL WORLD.

For a number of years there were separate places to be filled in the electrical field by a weekly and monthly publication, but owing to the evolution of the industry conditions have arisen which make it desirable from the standpoint of the manufacturer, the reader, the advertiser, and the publisher that these two important periodicals should be consolidated.

The Electrical World and Engineer is in itself a combination of the Electrical World and the Electrical Engineer. The Electrical World dates back to 1874 and was always recognized in the industry as incontestably the leading electrical paper. The Electrical Engineer was published separately from 1882 to 1899 and held the second position in importance in the field.

The progress of the industry having reached a point where it was desirable that these two papers should be combined and thereafter be published as one large weekly paper, the present owners took the necessary steps to accomplish this purpose and the Electrical World and Engineer was the result. During the past seven years this paper has more than ever occupied a unique position among technical journals, in that it has been accepted the world over as the one great exponent of the electrical art.

The American Electrician through its predecessor, Electrical Industries, dates back to 1889. Its subscription is the largest of all electricai journals, and it has earned for itself the reputation of being the only strong electrical monthly ever published.

Although the paid circulations of the two papers have overlapped less than 10 per cent., the tendency has been steadily toward a greater similarity in the character of the reading pages. Notwithstanding the considerable sacrifice on the part of the publishers, the consolidation will be justified, as the result will be an electrical journal of unprecedented strength, combining the engineering, technical, practical and commercial features of the component journals, and interesting every man engaged in the art or industry, from the consulting engineer or the superintendent of the large power station to the engineer of the isolated plant or the smallest electrical contractor.

The first issue of each month will contain the special practical features which have heretofore characterized the American Electrician. The second issue of the month will be the regular export issue, and, as in the past, every effort will be made to extend the foreign field for the benefit of those advertisers who are interested in export business.

The advertising rates in the Electrical World will be based upon the page unit instead of the inch, but the present flexible form of contract, which has met with so much favor, will be retained. That is to say, an advertiser who agrees to use a certain number of pages during the year, the space to be divided as he desires, and who for any unforeseen reason fails to use the entire number of pages contracted for, will pay for the advertising actually published at the rates applying to that amount of space.

NEW SLOW BURNING WEATHERPROOF WIRE.

50,000 lbs. Nos. 14, 12 and 10 brand new American Steel & Wire Slow Burning Wire in original coils, just as received from factory.

Also new Stranded Slow-Burning Wire on reels, sizes 2/0 and 3/0.

FEEDER WIRES.

The following Stranded Feeder Wires in stock for immediate shipment:
500,000 C. M.—60,000 lbs.
400,000 C. M.—150,000 lbs.
2/0—90,000 lbs.

SOLID CONDUCTOR WEATHERPROOF WIRE.

All sizes from No. 14 to No. 1. Some of it brand new and some second-hand.

LEAD COVERED CABLES.

An enormous stock of new and second-hand "Safety" Rubber Insulated lead covered cables from size No. 14 to 500,000 C. M.

INCANDESCENT LAMPS.

100,000 brand new General Electric Incandescent Lamps, in original cases, just as shipped from factory, packed 200 and 400 to the case. They are all 8-candle-power, 100, 101, 102 and 103 voltage, Edison Base. In case lots, each, 11 cts.

25,000—Brand new General Electric Incandescent Lamps, natural colors: Ruby, Green, Amber and Opal, packed 200 and 400 to the case, Edison Base, 104 voltage, 8-candle-power. In case lots, each, 21 cts.

500,000—Second-hand, tested 8 candle-power Incandescent Lamps, Edison Base, 104 to 110 voltage. Price in lots of 500, 6 cts. each.

RECEPTACLES.

1,000,000—No. 9171 Edison Base Receptacles in lots of 500, each, 2 cts.

KNOBS.

50,000—Split B. & D. Porcelain knobs, No. 10 to No. 14 wire, per thousand, $7.00.

40,000—No. 8 to No. 4 wire, per thousand, $10.00.

30,000—No. 6 to 2/0 wire, per thousand, $10.00. The above are brand new and in original packages.

CLEATS.

10,000—Single wire glazed porcelain cleats for 500,000 C. M. cable, brand new, in original packages, per thousand, $25.00.

150,000—Brand new single wire glazed porcelain cleats for 3/0 and 4/0 wire, per thousand, $9.00.

CUT-OUTS.

13,000—30 Ampere D. P. M. L. Porcelain plug cut-outs, Edison pattern, per gross, $12.00.

PORCELAIN TUBES.

All kinds of Tubes at 30 per cent. below market price.

DISPLAY PIECES.

3,000—¼ circle segments, stars and other fancy pieces which we are offering at 4 cts. per receptacle. They are on wood and wired ready for use.

SWITCHES

500—Double pole, single throw, slat base with removable terminals, in all sizes. Write for our list.

CARBONS

10,000—New "Electra" cored and solid carbons, 9½ x ½ inch, per thousand $14.50. Other sizes also on hand.

Besides the above, we can furnish practically everything in the Electrical Line. Here is a chance to save anywhere from 30 to 50 per cent. on your regular supplies. You dare not overlook it.

DAYTON, OHIO

Builders of PUMPING MACHINERY, WATER WHEELS, AIR COMPRESSORS and POWER PLANT APPARATUS

COCHRANE Steam Separators save steam—coal—money.

They supply your engines with dry steam—which is more economical when used expansively than steam containing moisture.

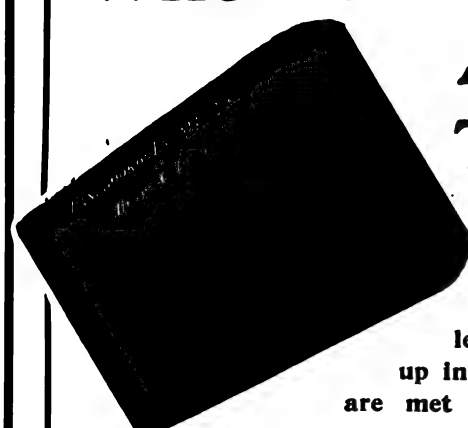
You get better cylinder lubrication, too, because water in the steam washes the oil from the surfaces of the cylinders and prevents thorough and economical lubrication.

Besides being thoroughly efficient in taking moisture out of steam, Cochrane Steam Separators take care of the large flushes of water whenever these come. Engine insurance of this kind is important, though the resultant economy from securing dry steam pays for the separator and pays for the insurance.

Shall we send you our Catalogue I-S?

HARRISON SAFETY BOILER WORKS
3124 North 17th Street, - Philadelphia, Pa.

When in Doubt Ask Tulley



Pretty nearly all the problems that come up in a power plant are met and solved in

Tulley's Handbook on Engineering

It tells how to figure the safe working pressure of boilers. How to calculate horse power of boilers and conduct boiler tests.

It explains the setting of engine valves, the operation of dynamos, motors, air compressors, refrigerating plants, and everything of this nature.

It contains 970 pages, has 400 illustrations and is handsomely bound in leather.

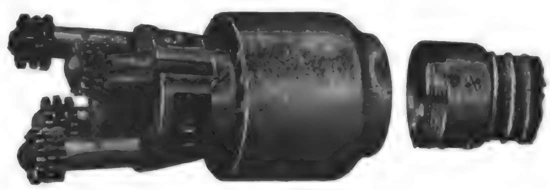
A money order for $3.50 will make a copy yours, and you will find it a mighty good investment. Fifth Edition just out. Thoroughly revised and right up to date. *64-page circular sent free.*

HENRY C. TULLEY & CO.

710 Wainwright Bldg. ST. LOUIS, MO., U. S. A.

WEINLAND TUBE CLEANER

THE RESULT OF 20 YEARS' EXPERIENCE



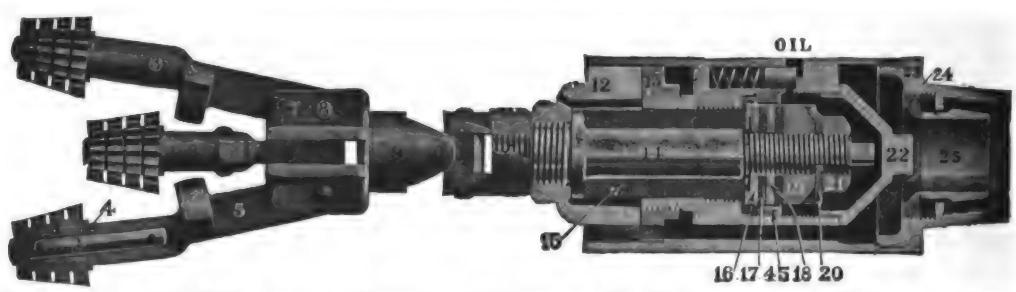
THERE are two kinds of economy. The first wouldn't buy a boiler tube cleaner—would go on making steam in scale covered boiler tubes in spite of the strain on the boiler and bank account. **One-sixteenth of an inch only, adds 15% to fuel bill.** All this to save the price of the cleaner. The second does buy tube cleaners and buys the Weinland because that has proved its superiority over all competitors.

We sell or rent Turbine or Power Cleaners, or Clean by contract, if you prefer that way. Write us also about Lagonda Tube Cutters, Damper Regulators, Reseating Machines, etc. Dollar savers all.

Philadelphia
Chicago
London, Eng.

THE LAGONDA MFG. CO.
SPRINGFIELD, OHIO

New York
Pittsburg
St. Louis



The Liberty Turbine Cleaner

Pays for itself the first time it cleans your boilers.

Are you sure your boilers are clean?

The fact that you use a light Turbine Cleaner and pass it through the tubes at frequent intervals, is no indication that the scale is removed. Other types of machines ride over the scale, whereas the Liberty removes it down to the iron, polishing up the tube and leaving it in as good condition as it was when the boilers were new.

The Liberty is the only Cleaner in existence that will do this.

One-eighth of an inch of scale means fifteen per cent more coal to evaporate the same amount of water as compared to clean tubes.

Liberty Cleaners are sent to responsible parties on trial.

In the end it is the cheapest Cleaner in existence.

WE ALSO MAKE THE "FABER" BLOW OFF VALVE

"IT WASHES IT'S FACE"

Liberty Manufacturing Company

3805 Susquehanna Street, PITTSBURGH, PA., U. S. A.

THE ECONOMY OF STEAM

is an important problem in every power plant. The cost of fuel is generally the largest item of expense and every pound of steam that is saved is made apparent in the coal bills.

A direct saving can be effected in most plants by using steam for various purposes at pressures less than the boiler pressure and for this service *Davis Pressure Regulators* are designed.

By their use any high initial pressure can be reduced any amount, and when once set to the desired delivery pressure they will automatically maintain that pressure constant irrespective of any fluctuation in the initial pressure.

They are simple in design, being constructed of few parts and have no springs, diaphragms, packings or toggles to get out of order or fail at inopportune times.

They are made for long, hard, continuous service and have established just such a reputation in the many years they have been on the market.

We want you to become familiar with the merit of these Valves —to determine their value by actual service tests—and we are willing to take all the chances.

To responsible concerns we will send a *Davis Pressure Regulator free on trial* with the understanding that it will be paid for if found entirely satisfactory after having been fully tested, or returned at our expense in the event of a failure.

We guarantee our goods and have confidence in them or we could not make such a liberal offer.

Our guarantee means something. It means we are responsible for the proper and satisfactory performance of DAVIS VALVES.

We also make Back Pressure Valves, Steam Traps, Exhaust Relief Valves, Damper Regulators, and other power plant specialties which are sold on the same liberal basis.

For Sale by Jobbers Everywhere. Send for Complete Catalog.

Write for Story of District Steam Heating

American District Steam Co.,

LOCKPORT, N.Y. CHICAGO, ILLS.

SKINNER ENGINES

You frequently hear of "self-oiling" engines melting out boxes and cutting guides and cross-heads. Why? Because the same filthy, hot, impure oil is simply splashed about the engine, no attempt being made to filter and cool it. Such engines are "self-grinding," not "self-oiling." Reason for existence—cheapness. The Skinner Automatic Oiling System is different—it costs something to make, and we charge you something for it. But you get your money back many times over.

SKINNER ENGINE CO.

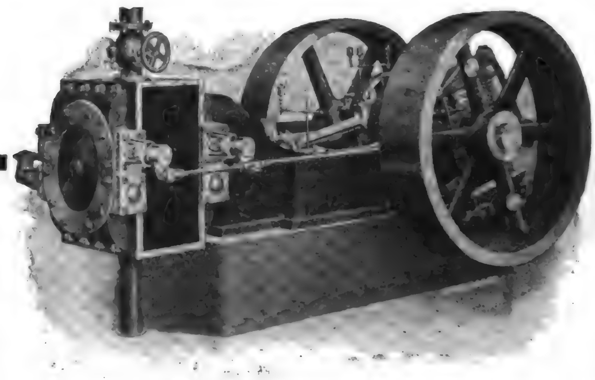
AMERICAN BLOWER CO., Detroit

W YORK CHICAGO ATLANTA LONDON



Slide-valve simplicity and speed, combined with Corliss economy, has been attained in the

Atlas Four-Valve Engine

The two inlet valves and two exhaust valves are worked by two separate eccentrics in perfectly straight lines without off-sets, cardan joints or other power-wasters and with none of the binding strains of rocker arms.

Note on the picture the entire absence of wrist-plates, dash-pots, releasing gear and other complications. The valves are placed directly in the heads, reducing clearance to a negligible factor. All this means economy in attendance, economy in coal and economy in first cost of electrical apparatus.

Pay Day

What Does It Mean to You?

No matter what your position may be, whether day laborer or office worker, if you are in that discouraged line of men who get the same pittance week after week, year after year without hope or prospect of anything better, it's time you appealed to the International Correspondence Schools. Ask them how you can in your spare time qualify for ***a better position, a higher salary, and a safe future.*** They will make the way so ***plain and easy*** for you that your only wonder will be that every worker in the world is not following the thousands who have already reached success over this highway.

If ***YOU*** want to get more money on pay day, simply mark and mail the coupon below. It puts you under no obligation to do this. ***Can you afford to neglect your opportunities?***

INTERNATIONAL CORRESPONDENCE SCHOOLS, Box 1025, SCRANTON, PA.

Please explain, without further obligation on my part, how I can qualify for a larger salary in the position before which I have marked **X**.

PIPE TAPS AND REAMERS

The constantly increasing demand for our Pipe Taps is the very best recommendation we could have. Special sizes made to order at short notice. When a customer orders on trial, future orders are sure to follow.
